One of the most urgent problems which American medicine must meet and help to solve is that of the rural area, in which for one reason or another economic and social conditions are bad and medical care is sadly deficient. If doctors could be induced even by subsidies to locate in such places, the quality of care would still be substandard, for the doctor cannot do his best without tools. The solution lies in the planned establishment of hospital centers under county or local control which will give the doctor a place in which he can work satisfactorily and from which medical and hygienic knowledge can diffuse into surrounding communities. These deficient areas are scattered all over this country, and their salvation is a state and economic problem. The doctor will gladly join, but he cannot carry both the economic and the medical burdens alone. The rectification of the social and medical deficiencies in these areas will remove the most important claim to consideration of the advocates of socialized medicine.

The medical as well as the social and economic problem of the immediate and more distant future will be solved by a continuation of the evolution and orderly growth of medicine and social activities.

A definite program looking to the elimination of gross deficiencies in rural and other depressed areas, and the continued advance in medical education and consciousness of social responsibility with maintaining of standards, will go far toward attaining this desirable goal.

The American way of life is to us the most desirable. We have a degree of individual freedom (in spite of minor inconveniences of rationing and taxes) found nowhere else in the world.

Our very national life has been threatened first from the Atlantic and then from the Pacific. We are fortunate in having strong allies whose immediate aims are ours. But our real aim in this war is to maintain our American way of life. This is the reason our soldiers are willing to serve and suffer. And so it is the duty of those of us at home that we preserve for those who fight for us their ideals of freedom and see to it that our doctors in the service return to a free medical world unencumbered by the deadening influence of state controlled medicine and politically dominated practice.

Their military service will be easier and more effective if they are assured that during this war we are preparing for an enduring economic peace with maintenance of educational and medical standards and the preservation of liberty and free enterprise.

SEPTICEMIA AND PURPURA WITH ADRENAL HEMORRHAGE IN THE ADULT

(WATERHOUSE-FRIDERICHSEN SYNDROME)

A DISCUSSION OF THE ROLE PLAYED BY THE ADRENAL
GLAND IN THE PRODUCTION OF THE SYNDROME;
REPORT OF TWO ADULT CASES.

H. B. THOMAS, M.D.

YORK, PA.

AND

C. D. LEIPHART, M.D.

Assistant Surgeon (R) U. S. Public Health Service

NEW YORK

The syndrome of bleeding into the skin and other organs including the adrenals in the presence of a severe septicemia is becoming more frequently recognized by clinicians both here and abroad. At the present time almost 150 cases have been reported, the vast majority being in infants and young children. A careful search of the literature has revealed only 19 instances in adults. A recent epidemic of meningococcal meningitis has given us the opportunity to observe 2 typical instances of this unusual syndrome in adults. With prompt recognition plus intensive specific therapy, more victims of this almost uniformly fatal malady might be saved.

At the present time there remains a great deal of confusion concerning the etiology, the pathogenesis, the role of the hemorrhagic adrenal destruction and the status of the thymolymphatic system in the production of this syndrome. As more cases are being studied and with more information concerning capillary physiology, some of the unknown problems are nearing solution.

Fulminating purpura with bilateral adrenal hemorrhage was described as early as 1894 by Voelcker.¹ In 1898 Garrod and Drysdale,² Battin³ and Andrewes⁴ published case reports, which was followed in 1900 by 1 from Talbot.⁵ Blaher and Bailey⁶ in 1901 reported 4 cases of hemorrhage into the skin and adrenals and suggested that the etiology was a fulminating hemorrhagic smallpox. The same year Little⁷ presented 4 cases of his own, with a review of 12 others which he stated were "hitherto unclassified." Waterhouse⁸ in 1911 described the syndrome with an accurate picture of the symptomatology and pathology but contributed nothing to the etiology. Most authors credit MacLagan and Cooke⁹ in 1916 with being the first to find a specific bacterial agent when they recovered the meningococci in 2 fulminating cases of cerebrospinal fever. It

should be noted that Andrewes¹⁰ in 1906 reported this organism in what is perhaps the first bona fide adult case. Friderichsen¹¹ in 1918 published reports of 2 cases of his own and made an extensive review of 28 others. Since then the syndrome has gradually assumed its present title. Aegerter¹² presented a study of the symptomatology, pathology and etiology in 1936. In his review of 55 collected cases plus 2 of his own he found only 6 in adults, with 70 per cent under the age of 2 years. Since then all reported cases have been in children except adult case reports by Foucar,¹³ Simpson,¹⁴ Craster and Simon,¹⁵ Kwedar,¹⁶ Carey,¹⁷ Leone,¹⁸ Drummond and Tooke,¹⁹ Grace, Harrison and Davie²⁰ and Sharkey.²¹

ETIOLOGY

Investigations to determine the responsible bacterial agent were not as common in the early cases as in later years. In Friderichsen's collection of 30 cases blood culture was reported in only 12 instances, 7 of which were sterile and the remainder included a variety of organisms. Waterhouse's case yielded a sterile post-mortem blood and spinal fluid culture, and it was his opinion that cultures were sterile in most cases. Previous to the work of Andrewes and of MacLagan and Cooke in demonstrating the meningococci, bacterial agents cultured from the blood, skin and adrenals included the streptococcus, staphylococcus, pneumococcus, colon bacillus, *B. pyocyaneus*, and the Friedländer bacillus. Blaher and Bailey suggested that the etiology was a fulminating hemorrhagic smallpox; Dudgeon²² found a *Streptococcus aureus* in 1 case and a pneumococcus in another. Little demonstrated streptococci in sections of the skin.

After some years of investigation by modern bacterial methods it seems definitely established that the most frequent invading organism is the meningococcus. In a review of this syndrome Sacks²³ states that, since MacLagan and Cooke's report, of 21 cases in which definite etiologic data are included, 60 per cent, or 12 cases, were due to the meningococcus while the others were sterile or showed growths of *Streptococcus haemolyticus*. Sacks also notes that Bamatter²⁴ in 1934 found that only four bacteriologic examinations had been done ante mortem. It is the growing opinion

of a number of students of this condition that, with an increased number of case studies, *Neisseria meningitidis* will be indicted as the sole etiologic agent. In our review of the 21 adult cases including 2 of our own the meningococcus has been cultured or reasonably well identified on sections in 16 reports. In the remainder no organism was seen in sections, and cultures of blood and spinal fluid when done had revealed no growth.

At the present time, however, the meningococcus is not universally accepted as the sole etiologic factor. Recently Lindsay and his associates²⁵ reported 7 cases in children in which the heart's blood culture showed 4 to be positive to *Neisseria meningitidis*, 2 to *Haemophilus influenzae* and 1 to *Neisseria flava* II. In case 2 by Sacks the postmortem culture revealed a pneumococcus type I. The occasional finding of the pneumococcus is of great interest because of its characteristic like that of the meningococcus in producing purpuric skin lesions as shown by Mair²⁶ and by Julianelle and Reimann.²⁷

PATHOGENESIS

The concept that the hemorrhagic destructive lesion of the adrenals is the cause of the dramatic death of the victim has been accepted by most observers for a number of years. That this theory is not tenable is attested by animal experimentation, reports of recoveries and of autopsies on cases in which there was no adrenal involvement or a unilateral cortical lesion.

Adrenalectomized dogs lose appetite and become weak and listless, with vomiting, diarrhea, pronounced depression, feeble pulse and low blood pressure and metabolic rate. These symptoms are faithfully followed by patients with the Waterhouse-Friderichsen syndrome with one important exception, and that is the time that it takes for these features to appear. The onset of the symptoms to the time of death of the patient is usually measured in hours and seldom runs over two days at the most. In adrenalectomized dogs in the average, survival time in 74 subjects was found by Rogoff and Stewart²⁸ to be seven days. The onset of the changes in the experimental animal is slow and insidious, the subject becoming apathetic and sluggish, weak in the hind legs, then lying prostrate, refusing food and often vomiting. Muscular twitchings and frank convulsions develop, respirations becoming slow and labored and eventually ceasing. In man these identical changes are rapid but complicated with profound overwhelming infection that has produced sepsis and hemorrhagic phenomena.

In the reported cases of recovery in the Waterhouse-Friderichsen syndrome the clinical features are identical with those that are fatal. It is difficult to visualize even mild bilateral hemorrhagic lesions of the cortex which could produce such profound disturbances of the individual and still be able to recover complete function. While it is known that one eleventh to one fourth of one adrenal cortex is sufficient to maintain life in the experimental animal, it is not reasonable to suppose that rapid destruction of the major portion of the cortex will produce the syndrome rapidly, because that is not the case in complete adrenalectomy.

Regeneration of the glands can likewise be eliminated. The MacKays and Addis²⁹ have shown that hyperplasia of the cortex of one gland does occur after excision of the other, but that it is an inactive process taking nearly three months to develop and requiring most encouraging conditions which are not present when disease is present. As far as rapid destruction of the glands is concerned, regeneration is far too slow and uncertain to play any part in staving off insufficiency. Any process-resembling regeneration is seen rarely in company with disease of the organ itself.

The sequence of events in the production of the Waterhouse-Friderichsen syndrome is undoubtedly initiated by a bacterial invasion of the blood stream. That in most cases of meningococcal meningitis show a stage of dispersion in the blood stream after a period of local infection in the upper respiratory tract is generally accepted. The cause of the wide hemorrhagic phenomena of the skin, adrenals and many other tissues has been thought to be the direct action of the bacteria or their toxins on the walls of the capillaries.

Removal of the adrenal medulla will produce no definite change in the physiology of the animal, and it has been noted by many investigators that the surgical removal of both adrenal cortices will not produce the symptoms of insufficiency for at least several days. Because of the great rapidity with which symptoms uniformly appear in an apparently healthy individual, it is difficult to ascribe their origin to adrenal insufficiency. However important the adrenal glands are to the economy of the individual, they are just one of the tissues of the victim that manifest this capillary weakness. If the patient would not succumb in such a rapid manner, the loss of the adrenal cortex hormone would present a very serious complication in a few days.

It is our opinion from observation of our 2 cases and the study of a large number of reported ones that death occurs from an overwhelming septicemia with a superinduced profound state of shock. The reason for massive adrenal hemorrhage exciting the interest of most observers is that it has long been known that loss of the adrenal cortical hormone produces fatal disorders of systemic functions that are identical in most features with those of surgical or traumatic shock. However, the duration of the illness is too short for the loss of this hormone to be noted. Aegerter states that, if there is a pronounced fall in the blood sodium concentration, one may assume that death is at least partly due to the collapse following adrenal destruction. With an illness of such short duration, the blood serum sodium cannot fall appreciably. Cutler, Power and Wilder³⁰ point out that in Addison's disease the blood sodium may be within normal limits and sodium balance studies are necessary to determine the abnormality of sodium metabolism. It might also be added that many observers have noted that, in the development of shock of any cause, plasma loses sodium.

The clinical evidence for the concept that adrenal hemorrhage plays little or no part in the rapid death of the patient is furnished by Williams,³¹ who has

observed 17 children with fulminating meningococcal septicemia who came to autopsy. The clinical features of all the cases were much the same, but only 9 of them presented bilateral adrenal hemorrhage. Williams states that it was impossible to predict which of the cases would present adrenal involvement and which would not. In a detailed analysis of the two groups it is apparent that the two groups cannot be separated on clinical grounds. The classic clinical features were identical, as were the necropsy findings, with the exception of the adrenal hemorrhage in 9 of the 17 cases. It is Williams's opinion that adrenal hemorrhage is but an incident in an explosive disease process that overwhelms all bodily resistance.

SYMPTOMATOLOGY

The clinical picture is almost the same in adults as in the more frequently described infants. The patient usually has no prodromal complaints except what seems to be a mild upper respiratory infection. After a few days of mild malaise the serious symptoms appear and progress with alarming rapidity, so that the duration of the disease is measured in hours and not days. Chills, fever, sweating and manifest weakness appear together as the first complaints. General aching with abdominal pain or cramps is quickly followed by profuse vomiting of the stomach contents followed by bile. Cyanosis is usually extreme and appears early and is frequently the sign that attracts the attention of the family to the seriousness of the situation. In a few hours the fever is usually over 102 F., with a rapid, weak pulse and evident hypotension. Petechiae appear over wide areas and rapidly coalesce into large ecchymotic spots with amazing rapidity. The cyanosis plus the purpura usually alarms the family to the degree of obtaining medical advice, because in most case reports the physician seems to be called early in the course of the disease. There is no abnormality of the central nervous system on examination except a toxic delirium, which changes rapidly with convulsions to a deep coma and death.

Laboratory examinations are frequently meager and inconclusive because of the short duration of the disease. There is almost always a rather accentuated leukocytosis, with some shift to the left. Owing to the shocked condition of the patient it is frequently difficult to express a drop of blood from the skin for examination. Smear and culture of the purpuric areas as suggested by W. W. King³² and by McLean and Caffey³³ often prove of value in isolating the offending organisms, most frequently the *meningococcus*. The same organism is found in blood cultures in at least 60 per cent of the cases.

Boone and Hall³⁴ and Kwedar have reported finding the meningococcus in blood smears stained with Wright's stain. Chemical examinations of the blood are those generally found in shock.

Spinal fluid examinations are usually of no value in diagnosis but generally become abnormal in the last hours of the illness if death does not intervene too quickly.

PATHOLOGY

The pattern of pathologic features is much the same in all cases of infants or adults. The outstanding feature is bilateral adrenal hemorrhage, reported in more than 95 per cent of the cases. These findings vary from microscopic pinpoint hemorrhages to massive bleeding, converting the adrenal into a mass of blood. When severe there is complete destruction of the organ with scattered remnants of the gland remaining. When the bleeding is mild the medulla is usually more involved than the cortex. In 3 of the 55 cases reviewed by Aegerter the bleeding was unilateral and on the right side. The bleeding may extend into the perirenal fascia, and in 1 case noted by Aegerter the capsule had been ruptured, producing a hemorrhagic peritonitis. The capsule is usually tense and, when opened, resembles a blood cyst grossly. The microscopic picture usually shows a complete replacement of medullary tissue by hemorrhage and only remnants of cortical tissue remaining around the capsule. Bacterial stains frequently reveal the meningococcus in the tissues.

Sections of the purpuric skin lesions show engorged blood vessels in the corium, with occasional small areas of extravasation of blood. Postmortem findings in other organs are not constant; hemorrhage into the serosal cavities and intestinal tract are sometimes found. Pulmonary engorgement and injection of the vessels of the brain are frequently found. Other organs are not remarkable except for the prominence of the thymolymphatic system in the children who have succumbed to this disease. Enlargement of the thymus, lymph nodes, Peyer's patches and spleen has led to a discussion whether there is some relation between this condition and the rapid death of the patient. While some observers believe that the prominence of the thymolymphatic system is too frequent to be coincidental, no evidence of its presence is found in adults, who succumb just as rapidly as children. The definite relation of these findings remains unknown at the present.

REPORT OF CASES

CASE 1.—A white man aged 34, of normal health except for a mild upper respiratory infection of three days' duration, on the third day (Dec. 26, 1942) when returning from work complained of weakness, fever and general malaise. He was seen by his physician and found to have a temperature of 104 F. At 5 o'clock the following morning he became unconscious, and the skin became purple and mottled in appearance. During the night he vomited and had severe pains in the back and epigastrium. He was admitted to the York Hospital at 7 a. m. and died at 9:30 a. m. the same day. Physical examination showed that he was well developed and had cyanosis, dyspnea, a restless delirium and a skin that was covered with large areas of purple macules, some of which were confluent. The temperature was 105 F. rectally, the pulse rate 120, the respiratory rate 36 and the blood pressure not obtainable. Other than moist rales at the bases and evidence of shock and sepsis, the physical examination was not remarkable. No laboratory data were obtained because of the short duration of the illness.

Postmortem examination by Dr. Lewis C. Pusch revealed in general that the patient was well developed and very well nourished. The body length was 167 cm., the estimated weight 100 Kg. The face had a diffuse ashen purple-gray hue. The chest and abdomen were mottled with sharply defined, irregularly shaped, largely confluent, nonelevated areas of a purple hue, a few millimeters to several centimeters in diameter, which on section appeared to be due to hemorrhage into the derma. More discrete similar areas were present on the back. The thighs and legs were of a diffuse purple hue.

The pleural and pericardial surfaces of the thorax were smooth and glistening. A few black-reddish brown, circular, scarcely elevated plaques, several millimeters in diameter, were

found in the visceral pleurae, which otherwise was of a dull gray-brown-purple hue. The right lung weighed 660 Gm. The pulmonary vessels were grossly normal. The bronchial mucosa was gray. Calcified foci were found in the tracheobronchial nodes. The pulmonary substance was diffusely spongy, moist and brownish red. The left lung weighed 660 Gm. and resem-

Fig. 1 (case 1).—Section of lung, $\times 83$. Hemorrhagic disruption. Extravasated blood in pulmonary parenchyma can be seen in a dark matrix of extravasated blood.

bled the right lung in every respect except that the bronchial tubes did not contain mucus but a reddish brown fluid, and the bronchial mucosa was red-brown. The thymus was inconspicuous.

The aorta was elastic; brownish red hemic pigmentation of the intima was noted.

The heart weighed 430 Gm. It was unremarkable on dissection except that the myocardium was somewhat soft.

The peritoneum was smooth and glistening.

The stomach, intestine, biliary tract and pancreas were grossly normal on dissection. The liver weighed 2,225 Gm., had a smooth capsular surface and was brownish gray. The cut surface was the same color, relatively homogeneous and of normal consistency.

The spleen weighed 250 Gm. and was grossly normal on dissection.

The right kidney weighed 195 Gm., the left kidney 300 Gm. The cortical surfaces were smooth and gray. The cortex was 1 cm. thick and gray with striations obscured. The medullas were 2 cm. thick and were red. The renal pelvis were grossly normal. A 1.5 cm. cortical cyst was present in the right kidney.

The bladder was grossly normal and contained approximately 100 cc. of clear brownish yellow urine.

Both adrenals were diffusely enlarged. On serial gross sections both were found to be occupied diffusely by diffusely reddish black hemorrhagic infiltration. The dimensions of the right adrenal were 7 by 3.3 by 1.5 cm. and its weight 13.5 Gm.; of the left adrenal 6 by 3.5 by 1.5 cm. and 12.5 Gm.

Microscopic examination by Dr. Pusch revealed that the sternal bone marrow was normal.

There were acute passive congestion and edema of the lungs. The capillaries as well as the arterioles and venules were engorged with blood, and the alveoli in general were partly collapsed, although areas of compensatory emphysema were seen. Within the capillaries the erythrocytes were normal and

the leukocytes fairly numerous. The latter consisted chiefly of monocytes, nonsegmented neutrophils and lymphocytes. In an occasional instance groups of eosin stained, ill defined, minute diplococoid objects of meningococcal morphology were distributed throughout the cytoplasm of both intracapillary and intra-alveolar phagocytic cells. There was also a considerable amount of intracellular brown pigment. Some alveoli were empty, while others were filled with serum, erythrocytes and macrophage cells.

In a bronchial lymph node the capillaries and sinuses as well as the interstices of the lymphatic cords were engorged with blood.

The myocardial fibers were swollen and pale, in part fragmented and in part disintegrated. Within one disintegrated fiber a group of the eosin stained diplococoid objects noted in the lung were seen; another group occurred within a small patch of fibrin and histiocytes attached to the mural endocardium. An occasional instance of perivascular leukocytic infiltration was encountered, also an occasional small focus of interstitial hemorrhage.

The esophagus, stomach, intestine and pancreas were not remarkable.

Toxic degenerative alteration of the liver was seen in granular cytoplasmic swelling and vacuolation of the hepatic cells, with pyknosis. Leukocytes were numerous in the sinusoids. The diplococoid bodies of meningococcal morphology noted in the lungs and heart could be found in occasional instances in the liver, occurring in groups, free and intracellularly in hepatic cells and in Kupffer cells. There were also intracellular granules of a brown pigment.

In the spleen acute passive congestion, an increased number of leukocytes in the pulp and questionable reticuloendothelial hyperplasia were observed. Groups of the minute meningococoid bodies were rather readily found, chiefly intracellularly. There was also a considerable amount of coarsely granular brown blood pigment.

Fig. 2 (case 2).—Section of lung, $\times 835$. Capillary engorgement, as seen in shock, intra-alveolar hemorrhage and blood pigment in macrophage cells within alveoli. Many of the granules undoubtedly are artefacts occasioned by the embalming process. A few intracellular diplococoid bodies can be seen.

The adrenal glands were diffusely and decidedly hemorrhagic, with structural disruption and disintegration. The hemorrhage was of recent occurrence, without organization or phagocytosis of blood pigment. It extended into the periadrenal fascia. Only an occasional small patch of intact and uninvolved medullary

and cortical tissue was found, chiefly as extracapsular adenomatoid cortical nodules, which in some instances also were destroyed by hemorrhage. Groups of the eosin stained diplococoid bodies were found also in both adrenal glands, occurring both free and intracellularly in parenchymatous and in phagocytic cells. Multiple sections of the adrenal arteries and veins presented normal structures throughout.

In the kidneys there was granular cytoplasmic swelling of the tubular epithelium. The glomeruli were congested. There were a few interstitial areas of hemorrhage in the medullas.

There were edema and focal lymphocytic infiltration of the bladder, but in general nothing of note was observed.

Fig. 3 (case 2).—Section of skin. $\times 835$. Capillary engorgement, vasculitis, thrombosis and hemorrhagic extravasation. Intramural and perivascular infiltrations of granulocytes, monocytes and lymphocytes. Some diplococoid bodies can be seen, but the majority of the granules are artefacts resulting from embalming.

In a section of skin through one of the purple areas of the abdominal wall dilated capillaries in the dermal papillae and an occasional small area of hemorrhage were seen.

CASE 2.—A white man aged 46 was admitted to the York Hospital on May 1, 1943 and died thirty-four hours after the onset of his illness. For several days preceding his illness he noted a mild upper respiratory infection. The night preceding the onset he felt reasonably well except for a mild headache. While at work on the morning of admission he was seized with severe chills, became very weak, vomited a turbid yellow liquid and perspired freely. He went to the first aid station, where his temperature was found to be 105 F. He was admitted by ambulance immediately with a provisional diagnosis of pneumonia. His past medical history was irrelevant.

On admission he was somewhat irrational and slightly cyanotic. He complained of general pains, particularly over

the lumbar region. Physical examination was generally unremarkable except for an occasional rate at each base. The temperature was 105 F., pulse rate 110, respiratory rate 30 and blood pressure 130/80. The catheterized urine was normal except for a trace of albumin; the hemogram showed a slight anemia and a leukocytosis of 40,200, with 84 per cent neutrophils, 31 per cent being of the nonsegmented variety.

The platelet count was 273,000 and the spinal fluid was normal. No sputum was obtained. Two successive blood cultures revealed meningococci (type 1). Within five hours after admission the first meningococcal manifestations were noted on the back. The patient became more cyanotic, and large ecchymotic areas appeared over the whole body, including the ears, face and extremities. During the period the blood pressure dropped rapidly to 52/20 and remained at very low levels to his death. There was little change in the pulse rate, but the temperature dropped progressively to 99 F. During the last twenty-four hours the patient vomited frequently and was very dyspneic, restless, sweating and cyanotic. He manifested all the symptoms of profound shock. The therapy consisted of plasma, oxygen, epinephrine, saline solution and dextrose by vein and intravenous sulfadiazine. The patient died thirty-four hours after the onset of his illness.

Postmortem examination by Dr. Pusch revealed that the body length was 170 cm. and the estimated weight 80 Kg. The patient was well developed and well nourished, with confluent areas of ecchymosis, dark purple and of irregular configuration, several centimeters in diameter, covering the skin of both arms, back, thighs and legs. The body had been embalmed by arterial injection.

In the thorax there was no free pleural fluid or increased amount of pericardial fluid. There was one fibrous adhesion at the left base. The heart weighed 410 Gm. There was no dilatation. It was unremarkable on dissection, including valves and coronary arteries, except for epicardial petechiae. Each lung weighed 735 Gm. There was a moderate amount of mucus in the right bronchus. Both upper lobes and the middle lobe of the right lung were spongy, moist and brownish gray on section, while the lower lobes were spongy, heavy and blackish red and dark reddish brown. The visceral pleurae were black. There was no appreciable sclerosis of the aorta. The thymus was inconspicuous. The tracheobronchial nodes were moderately enlarged and blackish red and moist on section.

The peritoneum was smooth and glistening. There were no adhesions, ecchymoses nor petechiae. The gastrointestinal and biliary tracts were unremarkable on exploration. The pancreas was grossly normal on dissection. The right adrenal gland measured 6 by 3.5 by 1.5 cm. and weighed 15 Gm. It was diffusely occupied by hemorrhagic infiltration, being dark red-brown on serial cross sections with only a few minute yellow foci of cortical tissue apparent. The left adrenal measured 8 by 3 by 1.5 cm. and weighed 20 Gm. Serial cross sections were in every way similar to those of the right adrenal. The spleen weighed 240 Gm.; the pulp was soft and red. The liver weighed 1,950 Gm. The cut surface was light brown, with visible lobulations. The right kidney weighed 180 Gm., the left kidney 200 Gm. The cortical surfaces were smooth. The cut surfaces were predominantly gray, with ill defined striations.

Microscopic examination by Dr. Pusch of a section of skin from an area of purple discoloration revealed the capillaries engorged with blood, in some instances with associated hemorrhagic extravasation, and with intramural and perivascular infiltrations of granulocytes and monocytes.

The predominant feature of the lungs was that of hemic engorgement of the capillaries, with intra-alveolar hemorrhage and numerous alveolar phagocytes filled with blood pigment, seen chiefly in a section of the lower lobe of the right lung. In this section also were found a few intra-alveolar masses of eosin stained small diplococci. In 1 instance similar structures occupied the cytoplasm of a macrophage histiocyte. There were very few lymphocytes and granulocytes and no appreciable fibrin; free serum was seen. The pleural capillaries were engorged with blood.

A tracheobronchial lymph node showed definite hemic engorgement of the capillaries with large numbers of erythro-

cytes and erythrocytic debris in the sinuses as well as within the lymphatic cords.

Swelling and vacuolation of the muscle fibers of the myocardium, especially subendocardially, were noted.

The aorta was not remarkable at the site of section.

Hemorrhagic infiltration of the adrenal glands occupied a diffuse distribution and extended into the periadrenal fascia, but it was of unequal density, with complete disintegration of most of the structural organization in the sections, while in some areas the structure was well maintained. The cortical and medullary substances seemed to be equally involved. Where destruction was complete a tendency toward polymorphonuclear leukocytic infiltration was apparent. A few clumps of meningococoid bodies were seen, notable within a dilated capillary in the capsule of the right adrenal, where, enmeshed with a few leukocytes in a ball-like mass of fibrin, they constituted an embolus.

The kidneys showed few areas of hemorrhage, chiefly intratubular. There was moderate tubular dilatation.

Fig. 4 (case 2).—Section of liver, $\times 375$. Margin of focal necrosis, pyknosis, karyorrhexis, karyolysis and coagulative necrosis of hepatic cells with associated leukocytic infiltration. In sinusoids of bordering viable hepatic tissue leukocytes are numerous.

The spleen showed acute passive congestion, with areas of hemorrhage.

The predominant feature of the liver was the presence of focal necroses, chiefly midzonal within hepatic lobules but also occurring along central efferent venules, attaining a diameter of 0.5 mm. and characterized by acute passive congestion, granular cytoplasmic swelling of the hepatic cells and a considerable amount of brown pigment, which was free, within hepatic cells, and to a less extent within Kupffer cells.

The pancreas exhibited focal toxic cytoplasmic swelling and disintegration of the acinar cells of moderate degree.

TREATMENT

The treatment of this rapidly progressive dramatic malady requires prompt, decisive and heroic measures. With the isolated case, waiting for blood culture reports will mean that the patient has either died or progressed to a point at which therapy is of no avail. When the physician is confronted with an overwhelming septicemia, repeated blood smears should be frequently made in the hope of recognizing the meningococci. If pur-

puric spots have appeared, a smear of these areas should be made for the same purpose. In an epidemic of meningococcic meningitis specific therapy should begin immediately in all suspected cases.

Review of Adult Cases with a Summary of Available Clinical and Autopsy Findings

No.	Author	Year	Age	Sex	Comment
1. Little ⁷		1901	22	♂	No laboratory report, along with bilateral adrenal apoplexy and hemorrhagic phenomena there was also tuberculosis of lungs and adrenals
2. Andrewes ¹⁰		1906	53	♂	Meningococcic septicemia
3. Elliot and Kaye; Quart. J. Med. 10: 361, 1917		1917	Adult	♂	Meningococci in blood and spinal fluid
4. Herriek; Arch. Int. Med. 23: 409 (April) 1919		1921	21	♂	Meningococcic septicemia; autopsy limited to head
5. Herriek, ibid.....		1919	21	♂	Meningococcic septicemia
6. Kessel; M. J. Australia 2: 450, 1925		1925	30	♂	No laboratory report
7. Middleton and Duane; Am. J. M. Sc. 177: 648, 1929		1929	18	♂	Meningococcic septicemia
8. Boone and Hall ³⁴		1935	18	♂	
9. Foucar ²⁵		1936	20	♂	No laboratory report; sections of brain showed gram-negative cocci
10. Simpson ¹⁴		1937	Adult	♀	18 hours; coarse purpuric lesions in mucous membranes and skin with bilateral adrenal apoplexy
11. Craster and Simon ¹⁵		1938	42	♀	Meningococci found in placenta at autopsy
12. Carey ¹⁷		1940	27	♀	Patient recovered; meningococci recovered from blood and spinal fluid
13. Grace, Harrison and Davie ²⁰		1940	20	♀	No laboratory report; autopsy cultures of blood and organs sterile; gram-negative cocci found in kidney tuft
14. Grace, Harrison and Davie ²⁰		1940	40	♀	Laboratory reports not given; patient recovered
15. Leone ¹⁸		1941	43	♂	No bacteriologic report; no organisms noted in sections
16. Drummond and Tooke ¹⁹		1941	31	♂	Only adult case found in Negro; blood cultures sterile and no organisms found in sections; no hemorrhages in the skin, but diffuse ecchymoses of the conjunctiva, filling of the fourth ventricle, visceral pleura and many other structures
17. Drummond and Tooke ¹⁹		1941	40	♀	Cultures of blood, spinal fluid and heart's blood were sterile; sections showed rare isolated bodies resembling gram-negative cocci
18. Sharkey ²¹		1941	40	♀	Eight months pregnant; delivered dead fetus in eight hours; patient recovered; blood culture sterile but complement fixation test positive for meningococcus; no organisms reported in spinal fluid, which contained 21,000 cells
19. Kwedar ¹⁶		1942	58	♀	Meningococci found in blood smear and culture
20. Thomas and Leiphart.....			34	♂	No laboratory report; diplococci bodies of meningococci morphology in the cytoplasm of phagocytic cells in the lungs; in each adrenal these bodies were intracellular and extracellular
21. Thomas and Leiphart.....			46	♂	Meningococci present in blood; meningococci bodies found in lungs and adrenals

Therapy falls into two natural categories, specific and supportive. Chemotherapy with sulfadiazine in the form of the sodium salt should be given at once. About 0.05 Gm. per pound of body weight is the initial dose

intravenously. The total daily requirement thereafter is approximately the same amount. Efforts should be made to keep the sulfadiazine level to 15 mg. per hundred cubic centimeters. Sulfathiazole is the drug of second choice, followed by sulfapyridine and sulfanilamide. While there is a great deal of dispute about the combination of chemotherapy and serotherapy in the treatment of meningococcal infections, the seriousness of this syndrome makes it necessary to use all the weapons in our possession. There should be no waiting to see if the effects of the chemotherapy will suffice. Polyvalent antimeningococcus serum should be started along with chemotherapy in doses of 50 to 150 cc. intravenously, repeated every six to twelve hours for three doses and daily thereafter if necessary. The use of meningococcus antitoxin in 100,000 units intravenously may be substituted for the serum. We have had no experience with the antitoxin.

Supportive measures include the use of fluids with sodium chloride to combat the dehydration from vomiting and perspiration. With the appearance of hemocoagulation, large and adequate doses of plasma should be used to combat the shock. As there is always deep cyanosis and dyspnea, oxygen should be used early and as long as necessary. The use of adrenal cortex extract in large doses is justified primarily to combat the capillary permeability and only secondarily to replace the destroyed hormone. Adrenal cortex extract is given twice daily in 10 cc. doses or the equivalent dose of the synthetic cortical derivative desoxycorticosterone. One dose of epinephrine may be given; if there is evidence of improvement, this may be repeated. While this drug has been used by several clinicians, there is no evidence that its use is warranted in this condition.

The worth of this treatment is difficult to evaluate. In most cases progressive irreversible changes have probably taken place early in the disease almost before treatment has been instituted. Carey, Grace and his associates and Sharkey have reported recoveries with the treatment as outlined. Harries³⁵ reported 3 cases of fulminating meningeal infection with imperceptible pulses on admission to the hospital and yet made complete recoveries (ages unknown). Rucks and Hobson³⁶ report a case in a child with recovery. They also note a case by Bickel³⁷ with recovery; the details of this case are not available at the present time. Since these recoveries have all occurred since 1940 there is no good reason why a certain number of early or less severe cases should not be given the benefit of all that modern therapeutics has to offer.

SUMMARY

1. The syndrome of severe sepsis with hemorrhagic phenomena is being recognized with greater frequency by clinicians.

2. As more cases are being reported, the meningococcus has been found to be the chief, if not the sole etiologic agent.

3. Adrenal hemorrhage is merely part of the generalized bleeding diathesis and is not concerned per se with the rapid death.

4. These patients die from the effects of severe shock induced by the overwhelming sepsis.

35. Harries, G. E., in *Discussion on Modern Methods in the Treatment of Meningococcal Fever*, Proc. Roy. Soc. Med. 33: 560, 1940.
Hobson, J. J.: *Purpura Fulminans* (Waterhouse-Friderichsen Report of Case with Recovery, J. Pediat. 22:

— *Waterhouse-Friderichsen* (Septicémie et purpura) terminé par la

survécu avec guérison, Rev.

60: 1058, 1940.

5. It is impossible to predict from clinical and laboratory methods which cases exhibit adrenal hemorrhage.

6. The status of the thymolymphatic system plays no part in the adult cases. As the adults are similar to the juveniles, it may be assumed that it is almost never a factor.

7. Rapid diagnosis can be made by smears of the purpuric areas.

PEPTIC ULCER, GASTRITIS AND PSYCHONEUROSIS

AMONG NAVAL PERSONNEL SUFFERING FROM DYSPEPSIA

U. S. NAVAL HOSPITAL, CORONA, CALIF.

This paper deals with the diagnosis of the condition of Navy and Marine patients who present symptoms suggesting chronic disease of the upper part of the gastrointestinal tract. That such a group of patients constitutes a problem among military personnel has been emphasized repeatedly in current medical writings.

Gill,¹ after a thousand gastroscopic examinations carried out in an effort to "determine the value and indications for gastroscopy in the assessment of the service dyspeptic," has confirmed its value by uncovering 102 cases of gastritis in 308 cases in which the roentgenologic observations had been negative. It is surprising that the condition of none of the 806 patients studied was diagnosed as psychoneurotic. Flood² made psychiatric studies of 47 of 75 service patients suffering from proved peptic ulcer. Twenty-five presented symptoms of an anxiety state or an anxiety neurosis. No mention was made of patients presenting symptoms in the absence of roentgenologic observations. No gastroscopic study was reported. Rush³ reported on 200 dyspeptic service patients near the combat area in the South Pacific. In 106 cases no positive objective evidence of organic disease could be demonstrated, and the patients were judged to have functional disorders of the gastrointestinal tract. All of the patients were found to be in a state of either acute or chronic emotional ferment. Gastroscopies were not possible, and Rush expressed the belief that the group may have included some patients whose symptoms were caused by chronic gastritis.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

All of these investigations have one serious drawback: they fail to study each patient sufficiently to show whether he had solely a peptic ulcer, gastritis, a psychoneurosis or some other disorder, or whether he had a combination of two or more of these conditions. We believe that any value in the present investigation springs from the fact that all the patients are being studied in the same way, including roentgenologic, gastroscopic and psychiatric studies.⁴

For service patients, the problem of differential diagnosis of the diseases causing the symptoms just mentioned does not differ in any basic way from the problem for civil personnel in peacetime, but there are important minor practical differences. Since these patients are confronted with danger and unhappy maladjustments incident to service, some will knowingly and some unconsciously present symptoms in order to avoid danger or discipline. The similar tendency in civil personnel is less likely to express itself in symptoms because they have wide choice of occupation and are exposed to less danger. Furthermore, a physician in civil life is usually in no position to afford escape for a patient from his environment, whereas service physicians can survey a patient from the service back into civil life. This fact throws a heavy responsibility on the Navy physician, and the Navy owes him the time and the equipment to allow even more exact diagnosis than may be required in civil life. In civil life it is necessary to rule out malignant lesions and to try to relieve symptoms; in service it is also necessary to decide whether a man is to be retained in service.

METHODS (CARRIED OUT IN ALL CASES)

Roentgenologic methods are best suited for finding a duodenal ulcer and both roentgenologic methods and gastroscopy for showing a gastric ulcer, gastroscopy alone is best suited for visualizing various degrees of gastritis, and a psychiatric study is the only orderly way in which to reveal psychoneurotic tendencies. In each instance, roentgenologic examination preceded gastroscopy, so that it would reveal any esophageal lesion that might make gastroscopy dangerous. While the patient was under surface (throat) anesthesia, gastroscopy was performed by one of us (Schindler) by means of the Schindler flexible gastroscope after the stomach had been emptied with a large flexible rubber tube. The validity of gastroscopy for our purposes may be questioned only in that gastroscopy may fail to reveal minor inflammatory changes. A striking correlation between gastroscopic and microscopic observations in cases of gastritis has been demonstrated previously.⁵ There is no question that the gastroscope can show the severe, acute, ulcerative form of gastritis reported for civilian patients having duodenal ulcer.⁶ Nevertheless it is necessary to admit that misinterpretation of the gastroscopic picture is possible.

All but two of the psychiatric interviews were carried out by one of us (Underdahl). Each patient was studied with a total disregard for the presence or absence of organic disease. In no instance was a psychiatric diagnosis made in the absence of neurotic symptoms or simply because organic disease was not found. Whenever a diagnosis of psychoneurosis was

made, it was made because of multiple psychoneurotic tendencies, frequently dating back to childhood. A psychoneurosis can exist in the presence of organic disease, and with this method of psychiatric interview such a case is clearly brought out.

The other methods of study used were (with one exception, the Palmer acid test) those usually employed in the diagnosis of disease of the upper part of the gastrointestinal tract, such as fractional analysis of gastric contents, examination of stools for occult blood and routine examinations of blood and urine. In the performance of the Palmer acid test, the presence and location of pain and tenderness were noted (1) while the stomach was empty, (2) while 200 cc. of 0.3 per cent solution of hydrochloric acid was introduced for fifteen minutes, (3) while the stomach was empty and (4) while 200 cc. of 2 per cent solution of sodium bicarbonate was introduced for fifteen minutes. The complete evaluation of these studies must await the completion of a longer series.

SUBJECTS FOR STUDY

The patients were all of Navy or Marine personnel and can be divided into those who had had sea duty and those who had not. The former had been subjected to rough food, lack of milk and more fried food than is good for some persons and in some instances had had combat fatigue, seasickness, tropical disease and near starvation under unusual combat conditions. The others comprise those who had had duty only in the United States and had had the advantage of a good, regular diet, usually including milk. They correspond to patients of the same age group in civil life except that they too may have been apprehensive of service discipline and future danger. Fairly frequently a proportion of these subsisted at home and had an opportunity to make any needed dietary adjustments.

There is no satisfactory term to cover all the symptoms that the patients may present. Unfortunately "dyspepsia" is a synonym for indigestion in general, and properly used it includes symptoms of the large bowel as well. The symptoms with which we are concerned are those of the upper part of the gastrointestinal tract, anorexia, heartburn, nausea, vomiting and pain in the upper part of the abdomen. The pain is characteristically epigastric, but sometimes it is localized sharply in some spot included in the triangle bounded by the gallbladder, the spleen and the umbilicus. There may or may not be any reference of pain to a shoulder blade or through the body at the level of the origin of the pain. If there is vomiting it may or may not give evidence of bleeding or of obstruction of the upper part of the intestine. Tenderness may occur either at the location of the pain or elsewhere. Fairly frequently there are accompanying symptoms not referable to the gastrointestinal tract. Of these, headache, dizzy feelings, weakness, dyspnea and coldness and sweating of the hands and feet are examples. Less commonly there is idiosyncrasy to certain foods or other suggestive evidence of allergy in the patient's history or in the family history.

The more common diagnoses expected to fall within the scope of this paper are peptic ulcer (duodenal or gastric), chronic gastritis, duodenitis and various psychoneuroses. Because of the young age of most of the patients, mainly 20 to 30 years, duodenal ulcer should predominate over gastric ulcer. Malignant lesions and chronic cholecystitis will be uncommon.

4. We do not know of any report of a similar investigation.
5. Schindler, R., and Ortmayr, M.: Histopathology of Chronic Gastritis, *Am. J. Digest. Dis.* 9: 411-415 (Dec.) 1942.
6. Konjetzny, G. E.: Bemerkungen zu W. Fischer: "Einiges über Magengeschwür, Magenkrebs und ihre Beziehungen zueinander," *Med. Klin.* 37: 35-36 (Jan. 10) 1941.

RESULTS OF STUDY

The results of the study thus far are not valid statistically and will not be presented now in any detail. Forty-five unselected patients have been studied as outlined. In 23 instances peptic ulcer (duodenal only) was revealed by roentgenologic examination with characteristic deformities, and these comprise group 1. In 22 instances no peptic ulcer was found by roentgenologic examination and none has been found by gastroscopy. These comprise group 2. We are indebted to Commander John Camp (MC), U.S.N.R., who carried out the roentgenologic studies of the gastrointestinal tract.

GROUP 1.—In the 23 cases in which peptic ulcer was demonstrated by roentgenologic examination, a single duodenal ulcer was seen in each instance. Gastroscopy did not visualize any peptic ulcer because none was gastric. There were gastroscopic examinations in all these 23 cases, but in 3 of them gastroscopy was unsuccessful. In 1 case severe gastritis was present, in 5 there was a mild degree of gastritis, in 2 there was questionable gastritis and all of the others were negative. In the case in which there was pronounced gastritis, severe hypertrophic gastritis of the antrum and superficial changes of the lower portion of the anterior wall were seen. In 1 case there was only mild superficial gastritis associated with localized hypertrophic gastritis of the body of the stomach. Only these 2 cases correspond to the frequent cases of severe gastritis combined with duodenal ulcer encountered so regularly in civil practice.

Psychiatric interviews in this group did not reveal any one suffering from severe psychoneuroses at the time of examination, but 2 patients had moderate and 4 had mild neurotic symptoms. Two of these had had a reactive depression and situational neurosis respectively in the past. The remaining 17 patients did not have any neurotic tendencies. There was no apparent correlation between gastritis and neurosis, since in only 1 case were both present. In no instance in this group were the psychoneurotic symptoms severe enough to suggest discharge from the service. One patient was admitted with a diagnosis of gastric neurosis, but subsequently he was found to have three separate organic diseases of the upper part of the gastrointestinal tract (case 1). Psychiatric interview did not reveal any neurotic tendencies. Another patient was admitted suffering from gastric neurosis. After complete study he was found to have a duodenal ulcer as well as a neurotic background.

In each instance in this group the diagnosis, established with reasonable degrees of confidence, was duodenal ulcer.

GROUP 2.—In these 22 cases peptic ulcer was not demonstrated by roentgenologic examination. In no case did gastroscopy visualize an ulcer overlooked by roentgenologic examination. In the cases in which there were varying degrees of gastritis as visualized through the gastroscope, roentgenologic examination had not given any evidence of the gastritis. Gastroscopically, in 11 cases the gastric mucosa proved to be entirely normal. In 2 cases mild hypertrophic gastritis was seen. In 1 case pronounced chronic superficial gastritis of the body of the stomach combined with atrophic gastritis of the antrum was seen. In 3 cases mild and probably insignificant superficial gastritis was observed. However, in 3 cases there was outspoken

chronic superficial gastritis. In 2 additional cases a combination of superficial with atrophic gastritis was seen.

Psychiatrically this is a very important group. In 11 cases there was a definite psychoneurosis, mostly of the anxiety and mixed types, sufficiently severe to necessitate discharge from the service. In 3 of these 11 the psychoneurosis was superimposed on a constitutional psychopathic inferiority. Of the remaining 11 patients 6 had mild but very definite neurotic symptoms and only 5 were considered not neurotic, although 2 of the latter were restless and high strung. The diagnoses on admission varied widely, but only 1 of these patients was admitted originally to the psychiatric service. Of the 11 patients who had definite psychoneurosis, 6 had mild to severe gastritis and 5 had normal gastric mucosa. Of the 6 who had mild neurotic symptoms, 2 had gastritis and 4 had normal mucosa. Of the 5 without neurotic symptoms, 3 had mild gastritis and 2 had normal mucosa. One of the latter was suspected of malingering, although this was not proved.

In summarizing the differential diagnoses in this group, it is interesting that among these 22 cases there were 11 in which the diagnosis was made by gastroscopic examination and 9 of the remaining in which the diagnosis was made by psychiatric approach. In the other 2 neither psychiatric, gastroscopic nor any other study afforded a satisfactory diagnosis.

REPORT OF CASES

CASE 1.—*Diagnosis of "intestinal neurosis" changed to diagnosis of three separate organic diseases of the gastrointestinal tract.*

An electrician's mate, second class, aged 40, had been a telephone lineman who ate irregular meals. He had enlisted a year before admission to the hospital and had not had any sea duty. The patient had had laparotomy through the right lower abdominal quadrant in 1926 for "freeing adhesions," in 1932 appendectomy for typical symptoms of appendicitis and in 1938 herniorrhaphy. On one occasion in 1937 he had been awakened by severe pain in the epigastrium extending to the shoulder blades; the residual soreness lasted several days. Since 1939 the patient had had epigastric pain several times a week, a half hour to one hour after each evening meal. The pain was relievable by either food or soda. Later, in 1941, he had controlled all symptoms by eating his meals regularly, but after a drinking bout the pains returned and have continued to the time of writing of this paper except during his several months of boot training.

The patient was admitted to the U. S. Naval Hospital, Corona, Calif., in August 1943, complaining of epigastric burning pain and occasional vomiting. His physical examination gave negative results except for obesity (weight 232 pounds [105 Kg.], height 6 feet 1 inch [185 cm.]) and for the scars of his several operations. The first series of roentgenograms of the gastrointestinal tract was entirely negative, and the roentgenogram of the gallbladder with orally administered dye was negative. Analysis of gastric contents yielded normal values, the highest figure for free acid being 31. At this point, diagnosis of intestinal neurosis was made before a psychiatric interview was undertaken. On the second roentgenogram of the gastrointestinal tract a penetrating duodenal ulcer was observed. No abnormality of the stomach was seen.

Laparotomy was performed, and, in addition to an ulcer 1.5 cm. in diameter in the superior border of the duodenum, the gallbladder was subacutely inflamed, distended with purulent material and filled with small stones. Cholecystectomy was performed. Decision as to the advisability of surgical treatment of the duodenal ulcer was reserved until a later time to note the effect of the cholecystectomy on the patient's symptoms. The stomach appeared normal.

The patient made a satisfactory recovery from the surgical procedure, but for a month and a half after being ambulatory

he had nausea and vomiting after some meals and then, even while he was on a Sippy regimen, his old preoperative symptoms returned. Three stools were negative for occult blood. When a Palmer acid test was performed, the introduction of acid produced epigastric pain which lingered until the alkali was introduced. Gastroscopy revealed severe hypertrophic gastritis. The greater curvature of the antrum showed extensive pathologic changes. At first it protruded like a tumor and, though this bulging disappeared when more air was blown into the stomach, the mucosa still looked swollen and nodular. The mucosa of the sphincter antri was shiny and glistening but had many patches of adherent mucus. Veil-like layers of thin mucus were seen in the lowest portions of the anterior wall. The upper portions of the stomach appeared entirely normal. A third roentgenogram of the gastrointestinal tract did not show any change from the second examination. The duodenal deformity was unchanged, and there was no visualization of gastric pathologic change. A psychiatric interview did not afford any suggestion of neurotic tendencies.

The patient had a duodenal ulcer, chronic cholecystitis with stones and hypertrophic gastritis. Since his dyspeptic symptoms continued unchanged after cholecystectomy and under a subsequent medical regimen for his ulcer, he was surveyed out of the service. The symptoms which continue are caused most probably by the severe gastritis associated with the ulcer. It was thought inadvisable to operate on him for his ulcer because of the mechanical difficulties of performing gastric resection on a patient weighing 232 pounds (105 Kg.), because of the fact that symptoms of the ulcer had existed prior to enlistment and because of the extensive gastritis present.

CASE 2.—Diagnosis of duodenal ulcer changed to diagnosis of anxiety neurosis.

A yeoman first class aged 25 considered himself well until March 1943, one and a half years after enlistment, when he began to have pain in the midepigastrium, especially in the late morning and late afternoon and frequently on waking at night. Drinking of milk produced some relief. The pain was brought on by highly seasoned foods. It disappeared for several weeks at a time only to recur for weeks at a time. From June to August the patient was nearly free from pain while following a strict ulcer-regimen, but the pain recurred when a special diet was no longer possible. His pain then became intractable during several months of dissatisfaction with a superior officer.

The patient was admitted to the U. S. Naval Hospital, Corona, Calif., in December 1943. Physical examination gave negative results except for slight, questionable epigastric tenderness. He was in a good state of nutrition; he failed to respond to a Sippy regimen. On admission a series of roentgenograms of the gastrointestinal tract did not show any abnormality; a roentgenogram of the gallbladder with orally administered dye was also negative. No abnormality was found by gastroscopy, gastric analysis or the Palmer acid test.

The psychiatric interview and an interview with a parent yielded important information. Throughout childhood the patient had been shy and moody. He talked and walked in his sleep. On seeing a dead friend he became violently ill for a week. Later he wanted to study medicine but was again violently ill for a week after dissecting a cat. Fairly frequently he was depressed and felt that he might as well be dead. On the spur of the moment, a few days before he was to be married, he sent a telegram to his fiancée saying it was all off. He has never made further marital plans. The patient enlisted six months before Pearl Harbor but, with some college training, had hoped to be an officer and chafed under orders of a Wave officer in his department. In addition to the epigastric distress, periodic headaches developed. He also became more dissatisfied, nervous, worried and irritable. He frequently stated that he wanted to be discharged from the service. On sick leave from the hospital his epigastric pain became severe but he did not seek any medical aid. On returning from leave, though he was neat, clean and well nourished, he was irritable, critical, restless and apprehensive and frequently bit his finger nails.

The diagnosis was changed to anxiety neurosis (superimposed on emotional instability), and the patient was informed that he was to be surveyed out of the service. From then on, although he has remained as a patient for more than a month

while his papers were being cleared, he has complained less of pain while having a regular diet. However, he has been undependable in his work and has shown some irritability as before.

CASE 3.—Extensive superficial gastritis and mild psychoneurosis in a case of constitutional psychopathic inferiority.

A seaman first class aged 31 in the Coast Guard Service enlisted in June 1942 and did not have any overseas duty. He stated that he had had a "nervous stomach" all his life but he first complained of epigastric pain in October 1942. There was a past history of heavy drinking and excessive use of tobacco. The patient occasionally vomited and according to his story sometimes had blood in his stools. The pain centered in the epigastrium, but a separate gas pain, somewhat relieved by belching, tended to be in the left flank. Hot or cold drinks taken between meals aggravated the pains. There was little or no periodicity of the pain.

By August 1943 the epigastric pain became intense, and the patient was admitted to the U. S. Naval Hospital, Corona, Calif., on Dec. 29, 1943. Physical examination gave negative results except for a tremor of the extended fingers, voluntary rigidity throughout the abdomen, mild pes planus and external and internal hemorrhoids. The patient was restless and mildly apprehensive. Two series of roentgenograms of the gastrointestinal tract were negative. By proctoscopy the rectum and sigmoid were normal. There was no anemia, and three stools were negative for occult blood. Analysis of gastric contents showed distinct hypochlorhydria. The highest free acid figure was 8. (A test meal was used, but histamine was not used.) At gastroscopy striking changes were seen in the mucosa of the fundus. Everywhere there were thin layers of grayish, adherent mucus between and under the folds of the gastric mucosa. A diagnosis of extensive superficial gastritis was made.

Psychiatric interview afforded a separate diagnosis. Born to a family in which the father was rarely at home, the boy had frequent temper tantrums, was shy and irritable in crowds and was subject to moody spells. He lived in the tough part of town, had sexual intercourse from the age of 13 years and had gonorrhea several times. At the age of 14 years he started riding the freight trains. The expected subsequent career was interrupted only temporarily by an unhappy time in military school and public schools until he completed the twelfth grade. Since then the patient has been an admitted "bum," working seasonally in resort hotels, drinking, smoking three packages of cigarets a day and living with various women. At each place of employment he was restless and "sick and tired of it" and soon had to quit and move on. He was always introspective and was quickly aware of, and concerned about, any symptoms. During nervousness the patient had frontal and suboccipital headaches. His intelligence quotient is high; he writes a little, but not for publishing, thinks individually, is rather philosophic in his injudicious treatment of himself and has avoided crime because of the unpleasant sequelae. He has an excellent insight into himself and very much regrets not having studied for a profession. In addition to having chronic gastritis, this man has a psychoneurosis superimposed on a constitutional psychopathic inferiority.

SUMMARY

Forty-five consecutive patients of the naval service presented themselves at the U. S. Naval Hospital, Corona, Calif., with a variety of complaints referable to the upper part of the gastrointestinal tract. On the basis of symptoms and observations this group was divided into two classes: those that had a duodenal ulcer demonstrable by roentgenologic examination, and those that did not have an ulcer so far as could be seen by roentgenologic examination. In addition to the usual routine procedures employed in establishing the correct diagnosis, gastroscopy was performed on all of these patients and they were given a psychiatric interview.

Using this approach to the problem it was observed that, in the group of 23 patients suffering from duodenal

Research, where several persons have been working for about five years with the same V-1938 encephalomyelitis strain that was the causative agent of the aforementioned 10 human cases. For this reason we carried out the serum neutralization test with the serums of various employees in our institute, presuming that the evidence of antibodies against this virus could be considered a proof of a previous infection which passed clinically unnoticed.

TECHNIC OF SERUM NEUTRALIZATION

In all, 16 human serums were tested, 13 of which were taken from persons working in the Institute for Veterinary Research and the 3 remaining ones from country people. All persons were men.

The serums were tested against the original V-1938 encephalomyelitis strain isolated in 1938 and since then used for the elaboration of chick embryo encephalomyelitic vaccine. In order to eliminate possible individual oscillations of the virus titer, a 20 per cent suspension in saline solution was prepared from the brains of 6 mice

The three laboratory technicians (J. M., P. Ch., A. L.) of group 2 who formerly worked with the virus (elaboration of vaccine) have now not had, for two and three and one half years respectively, any contact with the virus.

Neither of the 3 employees of the institute (C. P., M. C., N. M.) in group 3 worked with the encephalomyelitis virus systematically. The laboratory technician C. P. helped two years ago, at one time or another, in the elaboration process of the encephalomyelitis vaccine. The person M. C. performed for the space of a month the postmortem examinations on 13 encephalomyelitic horses during the encephalomyelitis epizootic in the summer of 1943. The third person of this group, N. M., has for three years been bottling the formaldehyde inactivated encephalomyelitis vaccine and has never worked with the active virus.

The serums of the 6 persons of groups 4 and 5, who had never come into contact with encephalomyelitis virus, served as control negative serums for the other three groups. Three of these persons are

‡ Ratio between the titer of virus mixed with each of the immune serums and the titer of virus mixed with control serum.

inoculated with the virus forty-eight hours previously. From the supernatant part of this suspension, drawn off after a centrifugation at 1,000 revolutions per minute for ten minutes, serial hundredfold dilutions in saline solution were prepared, and to 0.5 cc. of each dilution the same amount of the serums on test was added, making a series of final dilutions of the virus ranging from 10⁻² to 10⁻¹⁸. After an incubation for two hours at 37 C. in a water bath, the serum-virus mixtures were inoculated intracerebrally (0.03 cc.) into 4 week old Swiss white mice. Surviving mice were discarded after fourteen days of observation.

EXPERIMENTAL

The 16 persons on test may be divided into five groups according to the degree of contact they have had with the encephalomyelitis virus.

Group 1 consists of 4 employees of the institute, all of them having been in continual contact with the virus for some years: three of them (A. D., A. R., A. Q.) have been elaborating the chick embryo encephalomyelitis vaccine for two and five years respectively, and the fourth one, a caretaker, has for more than five years handled mice, guinea pigs and rabbits inoculated with encephalomyelitis virus.

employees of the institute and the others are peasants living in the vicinity of the institute, where some cases of equine encephalomyelitis among horses have been observed.

The details and results of the neutralization tests are presented in the accompanying table. It is apparent that the serums of all persons who at any time worked with the encephalomyelitis virus contained specific neutralizing antibodies (the 10 persons of groups 1, 2 and 3). The amount of antibodies in the serums was sufficient to reduce the titer of the virus, which, in the presence of normal control serums, has been 10⁻¹⁰, to 10⁻⁵-10^{-3.33}, indicating an exceedingly high neutralization index of 10⁻¹¹-10^{-12.67}. On the other hand, control serums of persons who never came into contact with encephalomyelitic material did not even show any traces of neutralizing antibodies, because the titer of the fresh virus in saline solution, which has been 10⁻¹⁸, dropped, after contact with normal serums, to only 10⁻¹⁶. This may be easily explained by the attenuation of the virus by the warmth of the water bath.

The experiment further demonstrated that the amount of antibodies was practically equal in the serums of persons who have been working systematically and for a long time with the virus (groups 1 and 2) as well

as in the serums of persons who only occasionally came into contact with the virus (group 3). Of still greater interest is the fact that even a long period of contact with the encephalomyelitic vaccine, i. e. with inactive virus, was able to promote a considerable immune response in the person concerned (N. M., group 3).

The cases of group 2 give evidence that antibodies, once present, persist in the serum for a long time in the same intensity. Serums of persons who have not worked with the virus for the last two and three and one-half years showed the same virus neutralizing power as did the serums of persons who have been working with the virus uninterruptedly for various years (group 1). However, it is noteworthy that the serum of P. Ch., who stopped working with the virus three and one-half years ago, has also had the least—though still considerable—amount of neutralizing antibodies of all the serums on test, and a neutralization index of 10^{-10} .⁶⁷

The persons whose serums demonstrated high neutralizing antibody titers have in their records no evidence of any special clinical manifestations which could lead to a suspicion that they were suffering from a disease caused by the encephalomyelitis virus. Nevertheless, in view of recent reports by Casals and his collaborators¹⁷ and by Lennette and Koprowski,¹⁹ the possibility must be considered that our subjects did suffer from an encephalomyelitis infection which, owing to its mild course, has been confused with a current infection of grip. Only in 1 of our persons (M. C., group 3) was there some evidence that he might have become infected when performing the postmortem of 13 encephalomyelitic horses. His illness began a few days after the last autopsy with a severe headache, a high fever and nausea, which, according to his statement, persisted for three to four days. He was bled on the fifth day of the illness, when the headache disappeared and the temperature returned to normal. Though no virus could be isolated from his blood, his serum contained neutralizing antibodies for the Venezuelan encephalomyelitis virus. The neutralization index was higher than 10^{-3} but its exact limit was not determined at the time.

COMMENT

The recent communications by Casals and his collaborators¹⁷ and by Lennette and Koprowski¹⁹ concerning 10 cases of disease in man caused by the Venezuelan encephalomyelitis virus bring clear evidence of the high infectivity of this virus for man. However, the course of this infection in human beings appears to be much milder than that produced by the western and eastern encephalomyelitis virus. This mild course of the illness is probably the reason why, up to now, there have not been any reports on proved cases of encephalomyelitis in man from the areas where the Venezuelan virus is prevalent in horses. A striking feature of the present study is the high neutralizing antibody titers of the positive serums. They neutralized approximately 100 billion minimum lethal doses of the Venezuelan virus. The serums tested by Casals and his collaborators and by Lennette and Koprowski showed a lower, though still very considerable, neutralizing power. This amount of antibodies is certainly higher than that generally produced in human serums due to an infection with both the western and the eastern virus. Though this is probably a consequence of special immunologic characters of the Venezuelan virus, the influence of the very high titer of the Venezuelan virus in this phe-

nomenon must also be considered, since, in a recent study, we²⁰ were able to verify that, the higher the titer of the virus, the greater the number of lethal doses withstood by immunized mice; and it is precisely the Venezuelan virus which has the highest titer of the three viruses mentioned. On the other hand, it must be said that when we, on previous occasions, tried to produce an encephalomyelitis immune serum by means of repeated inoculations, even of the active virus V-1938 into donkeys, the serum had only a very low neutralizing antibody titer.²¹

As to the way in which people working with encephalomyelitic material become infected, there seem to exist various possibilities. The respiratory route of infection, described by Lennette and Koprowski, is one of them, and our case of M. F., an animal caretaker, could also be due to it. However, our neutralization test brings evidence that the transmission of the disease, or at least the promotion of an immune response, by contact, is also possible. This opinion could be corroborated also by the observation of Howitt,²² who tested the serums of a group of 9 persons who had been in contact with frank cases of human encephalitis. Seven of them had antibodies for the western virus. According to Howitt, several of these persons undoubtedly had an abortive type of encephalitis with slight fever that may have been responsible for the production of antibodies.

The interval after the onset of illness in which neutralizing antibodies appear seems to be very short.²² In the serum of our case M. C., antibodies were found as early as the fifth day of the supposed illness. According to Howitt,²² neutralizing antibodies for the western strain are found during the first two weeks after the onset of illness in 100 per cent.

Antibodies persist in the serum for a long time after the infection. We found high neutralizing antibody titers in the serums of 3 persons who did not have any contact with the encephalomyelitis virus for two and three and one-half years respectively. Howitt²² also demonstrated the presence of antibodies for the western virus at least two years after the onset of illness.

Finally, the question arises from the present study whether neutralizing antibodies for the encephalomyelitis virus in the serum of a person may be considered to be a proof that the person had some time before suffered from a disease caused by this virus or, on the contrary, that they are at least in some instances the consequences of a kind of immunization due to the repeated contact with encephalomyelitic materials. This possibility, mentioned also by Beard and Finkelstein,²⁴ is certainly corroborated by N. M., whose serum, though he has been working exclusively with the formaldehyde treated inactive virus-containing encephalomyelitis vaccine, had as high a neutralizing antibody titer as the serums of persons working with active virus. We do suspect, however, that the serums of the majority of our persons became positive as the result of a previous infection, because, with the exception of N. M., who during three years never failed to

come to work, all of them had to stay at home at one time or another on account of some grip infection. Several persons also remember very strong muscle pains, and 1 of them even a pronounced somnolence for three days. This mild and inconspicuous course of the illness caused by the Venezuelan virus is doubtless also the main reason for the lack of any communication about encephalomyelitis in man from areas where the disease is enzootic in equines.

In view of the work of Casals and his collaborators, of Lennette and Koprowski and of the present study, it may be said that the Venezuelan equine encephalomyelitis strain differs from both the western and the eastern virus not only by its immunologic character but also by a distinct pathogenicity for man.

SUMMARY

1. The serums of 3 laboratory workers and 1 caretaker of experimental animals, who have now been working for from two to five years with encephalomyelitic material, showed high neutralizing antibody titers (average neutralization index $10^{4.73}$).

2. The serums of 3 laboratory workers who worked previously with the virus but by now have not had any contact with encephalomyelitic material for two and three and one-half years had an equally high virus neutralizing power (average neutralization index $10^{4.44}$).

3. The same neutralization index showed also the serum of one person who worked only on very few occasions with the virus and of another who performed the dissection of 13 encephalomyelitic horses.

4. One laboratory worker, who is bottling the inactive virus-containing encephalomyelitic vaccine and who never came into contact with the active virus, also developed a high amount of neutralizing antibodies (neutralization index $10^{4.0}$).

5. It is possible that all the persons who have been working with the encephalomyelitis virus and who remember transitory illness with grippal symptoms have suffered from an encephalomyelitic infection.

6. Six persons (3 from the institute and 3 from outside) who have never had any contact with encephalomyelitic material showed no neutralizing antibodies at all.

7. Though the Venezuelan equine encephalomyelitis virus seems to be highly infective to man by direct contact, the illness is much milder than that produced by the western and eastern encephalomyelitic virus.

First Institution for the Epileptic.—The first institution specifically for epileptics was established at Gallipolis, Ohio, in 1890 and opened in 1893. The idea of the separation of buildings into many different groups was thoroughly carried out at the Craig Colony in western New York, to create for appreciative patients homes where they could be comfortable and have suitable occupation for life. Similar institutions have been developed at Woodstock, Ontario; Abilene, Texas, and Skillman, New Jersey. Numerous institutions care for both epileptic and mentally deficient groups: for instance, Sonoma, California; Mansfield Depot, Connecticut; Glenwood, Iowa; Lynchburg, Virginia, and Cambridge, Minnesota. Such institutions usually set aside several buildings for groups of convulsive patients and distribute those who are mentally deficient but without convulsive disorders in other wards or buildings. Such sharp segregation is not always practiced, and classification by temperament and interest seems sometimes more successful than classification by psychiatric diagnosis.—*One Hundred Years of American Psychiatry*, New York, Columbia University Press, 1944.

EXPERIENCES UNDER THE MEDICAL EXAMINER SYSTEM

IN A SEMIRURAL COUNTY OF THE STATE
OF MARYLAND

K. E. LANDÉ, M.D.

Pathologist; Director of Laboratories, Washington County Hospital
AND

S. R. WELLS, M.D.

Deputy Medical Examiner, Washington County
HAGERSTOWN, MD.

On June 1, 1939 a law was enacted in the state of Maryland removing the investigation of unexpected, unusual and violent deaths from the hands of the coroner and a lay jury and setting up instead a more modern system, creating the office of chief medical examiner and providing for medical deputies in each county.

Responsibility for the kinds of cases formerly handled by the coroner was transferred to the newly created office of medical examiner. The deputy medical examiner, as he is termed in the counties outside Baltimore, is appointed by the Maryland Post Mortem Commission from a list submitted by his county medical society. He is charged under the new law to view the body of the deceased at the scene of death and to examine the circumstances leading to death "when any person shall die as a result of violence, or by suicide, or by casualty, or suddenly when in apparent health, or when unattended by a physician, or in any suspicious manner." The medical examiner may then sign the death certificate or he may order a medicolegal autopsy for further information, investigation to be made by himself, the county or city police or all three.

It is obvious that close cooperation of the medical examiner with the state's attorney (district attorney) is essential. In fact, in the majority of instances when postmortem examinations are considered necessary they are authorized after consultation with, or at the suggestion of, the prosecuting authority of the county. However, the law setting up the machinery for the medical examiner's system in this state gives its official representatives the right to order autopsies independently of the state's attorney. A permit from the next of kin of the deceased is not required. Thus autopsies have been ordered by the medical examiner himself in cases with a medicolegal angle when the state's attorney was unavailable and in cases involving other than purely legal problems such as compensation insurance and public health.

Autopsies are performed in Washington County by the director of the local hospital laboratory, a certified pathologist with six years' special full time training in legal medicine. He was appointed by the chief medical examiner of the state of Maryland at the suggestion of the local county medical society. The pathologist is not called on to be present at the preliminary investigation, which takes place at the scene of death. His duties are confined to postmortem examinations and to testifying when called on before the grand and petit juries.

The medical examiner's findings are reported on a special form provided by the main office in Baltimore. In addition to personal data of the deceased and final diagnosis (cause of death as stated in the death certificate), a brief summary is written concerning the circumstances leading up to, or factors contributing to, the death and the manner in which it occurred. At

the end of each month a report summarizing and classifying that month's cases is filed with the central office. Should the necessity arise, advice and assistance from the chief medical examiner are always available. Photographs taken at the scene of death by the medical examiner (photography is not police routine in Washington County) have proved of graphic assistance in reconstructing cases at a later date. A number of prints have been admitted as evidence in court and have been instrumental in confirming otherwise debatable testimony.

In any case in which an autopsy is performed, the law requires that the detailed findings be filed with the main office in Baltimore. Copies of the report are sent to the local deputy medical examiner and to the state's attorney. The subsequent microscopic reports are usually forwarded only to the two first named medical officers.

However, should the microscopic investigation show results not anticipated at gross inspection and should the findings have some practical bearing on pending legal procedures, the state's attorney also is informed and the significance of the newly found evidence explained. If chemical analysis is desired (poison cases, alcoholism), the organs, blood, urine and stomach contents are sent (if possible by special messenger provided by the sheriff's office) to the chief medical examiner's laboratory in Baltimore.¹ The unavoidable expenses connected with toxicologic investigations have so far limited their application to a few cases only. Whenever ordered, an authorization from the state's attorney is procured in advance.

Fees of both medical examiner and pathologist are set by law. The former receives \$15 per case, the latter \$25 for each autopsy plus a small stenographic charge. Expenses are defrayed by the county. Compared with the former system the expenses under the new law

was 32,491 to 36,347. These figures may have shifted somewhat in favor of the city (Hagerstown) owing to a war boom (airplane factories). The population is fairly stable and according to the 1940 census was 97 per cent American born; 2.5 per cent represented the colored population of the whole county and 39 per cent that of Hagerstown proper.

TABLE 2.—Medical Examiner's Autopsies in Washington County, Md. (Five Years' Survey)

Year	Fatal Auto- mobile Acci- dents	Suicides	Hom- icides	Natural Deaths	Other Fatal Acci- dents	Rape, Abor- tion, Still birth	Poison ings; Varia	Total
1939 (7 mo.)....	2	3	1	5	3	1	1	16
1940.....	1	3	1	4	3	1	1	14
1941.....	1	2	..	6	2	..	1	12
1942.....	1	1	1	6	4	1	..	14
1943.....	..	1	2	9	2	..	3	17
1944 (6 mo.)....	2	1	..	3	3	..	1	10
Total (5 yr.) ..	7	11	5	33	17	3	7	83

Because of the fairly even distribution of rural and city population and also because of the stability of the native white group, the county has figured as a sample in several surveys of the National Institute of Health (cancer frequency, tuberculosis in school children, dental caries and others).

The 420 cases listed in table 1, seen in five years, allowed for 83 autopsies. By special order of the medical examiner, and at the expense of the county, postmortem examinations have been performed forty-nine times (11.7 per cent). However, included are 2 cases in which the costs have been defrayed by insurance carriers.

In cooperation with the medical examiner, but without his express order and without remuneration from the county, autopsies have been undertaken in 34 additional instances (8.1 per cent). Among the latter group have been listed 25 patients who died at the local hospital. Although medical examiner's cases *sensu strictiori* (victims of accidents, violence, and so on), the autopsies were done more in the course of the stepped up program of the hospital for a high percentage of autopsies than for any other reason. In this category, if possible, permits have been secured from the next of kin. Included in this group also are patients dying at the hospital with no relative available for an autopsy permit. Here the medical examiner has been instrumental in authorizing a post-mortem examination which would otherwise not have been feasible.

Eleven additional cases, although dying as patients of, and in, the hospital have been counted among the first group of 49 "ordered" postmortem examinations. These patients succumbed mostly in consequence of some event which led to court or insurance procedure after a short or long stay at the hospital.

The medicolegal autopsies just classified and enumerated represent, in their distribution among the different listings, a sample such as may easily be encountered in similar surveys in counties like Washington County, Md., as well as in large cities. From a purely criminologic point of view the 83 cases did not reveal any outstanding or unusual evidence except in 1 instance: A youth of 18 suffered severe lacerations of the right temple region in a motor-car accident. His deep and profusely bleeding wounds had to be sutured. Toward the end of the surgical intervention the patient suddenly vomited

TABLE 1.—Medical Examiner's Cases in Washington County, Md. (Five Years' Survey)

Year	Fatal Auto- mobile Acci- dents	Suicides	Hom- icides	Natural Deaths	Other Fatal Acci- dents	Rape and Abor- tion	Poison- ings; Varia	Total Cases	Autop- sies
1939 (7 mo.)	6	4	4	27	6	..	1	48	16

Total (5 yr.)	79	61	14	173	86	1	6	420	83

Fatal automobile accidents: Any fatal injury resulting from an auto-mobile, as being killed by a drunken driver or head on collisions.

Homicides: Include several cases of homicide with subsequent suicide of the culprit.

Other deaths, the home wor, dent, the electricity.

Poisonings: Here are listed some (by no means all) of the acute alcoholic intoxications, suspected poisonings and 1 case of phosphorus poisoning (rat poison swallowed by a child).

constitute a considerable saving for the county in spite of a much greater case load.

The figures of the following survey can be evaluated only when correlated with certain data about the county itself. Washington County, Md., contains 462 square miles and comprises mountainous fringes surrounding a very fertile farm valley region. According to the 1940 U. S. census it had 68,838 inhabitants. The distribution between rural and city population in 1940

1. Maldeis, H. J. Post Mortem Examination in Cases of Suspected Poisoning, *Am. J. Clin. Path.* 13: 165-169 (April) 1943

(intravenous anesthesia had been given) aspirated stomach contents and died a few hours later. The autopsy established as the cause of death suffocation due to aspiration. Besides the external lacerations there were no fractures of the skull and no brain lesions. Since the driver of the car in which the deceased was a passenger had been accused of manslaughter, the postmortem findings raised an important legal point of utmost significance for the defendant.

The cause of death could be sufficiently unraveled in all except 2 instances. One was a suicidal death in the neighboring prison farm where even chemical investigation did not disclose what kind of drug or chemical had been employed. However, other circumstantial evidence and the lack of any striking anatomic (gross and microscopic) findings seemed to confirm the assumption of a suicidal death. In the other case (sudden unexplained demise of a man age 20 after a debauch in *venere*) a mechanism of the kind recently suggested by Wilhelm Raab² was at least considered possible, again in the presence of irrelevant anatomic and toxicologic findings.

From the standpoint of pathologic anatomy the group of "death from natural causes" represents the most interesting source of gross and microscopic material, with considerable diagnostic variation and occasional unforeseen surprises.

COMMENT

It is not our purpose in this report to compare the medical examiner's system of Maryland with that of other states where similar legislation has been in force for many years (e. g. Massachusetts, New Jersey and New York). Here, as in these other states, one of the primary aims of the new setup is to contribute to an adequate pursuit of justice, either by providing evidence of crime or violence in cases with fatal outcome or by ruling out foul play in others.

In contradistinction to the former coroner's system, no political motives govern the selection of the medical examiner, who must be a duly licensed physician in good standing.

Since the incumbrance of the coroner's jury has been completely eliminated, the procedures have become less complicated. Investigations are undertaken not only whenever special circumstances of police interest call for them but also, and in much greater frequency, under routine conditions clearly defined by the law creating the medical examiner's office. This means that instead of a few conspicuous criminal cases, a large number of less obvious but nevertheless doubtful occurrences of sudden, unexplained deaths are investigated by an independent nonpolitical officer acting for the state.

The fact that not all the really pertinent cases have been investigated makes it necessary to mention certain weaknesses of the system. Occasionally physicians, more in the outlying rural districts of the county than in Hagerstown itself, have signed death certificates for persons who according to the definitions of the law fall clearly into the medical examiner's realm. It is understandable that in the case of the sudden, unexpected death of an old man or woman known to have suffered from attacks of precordial pain the local physician prefers to sign the certificate. If the deceased happens to have been a former patient of his, the medical examiner certainly will authorize him to do so (and a considerable number of cases are

handled this way, free of any charge for the county). However, there have been instances in which younger persons and children who died after a very short course of unexplained illness without medical attention have, contrary to law, not been reported. Here, usually, after the medical examiner finally had been informed of the circumstances and started his investigation, the body had already been embalmed and exhibited to friends and relatives. It is difficult, and feasible only for very cogent reasons, to order an autopsy under these circumstances in a small village community. Some difficulty too has been experienced in convincing the general public that the rumors of mutilation committed on the body of a deceased person are without foundation. It has been found best to describe the procedure as a surgical operation and to assure interested persons that all incisions are carefully sutured after completion of the "operation." Intercession by the family physician has been of great value in securing an autopsy permit from an otherwise adamant family. Although experiences of this kind have been the exception and have occurred mainly through ignorance of the law, they are cited in order to show some of the loopholes of the new system. The medical profession has been on the whole not only cooperative but also seemingly appreciative of the separation of this type of investigation from the hands of unqualified laymen.

The medical examiner's usefulness to the county depends to a great extent on his relation with the state's attorney and his staff. In fact, it stands and falls with it. No difficulties in this respect were encountered here through the change in law. The prosecuting attorney acknowledged the quasi-independent position of the medical examiner and made every effort to utilize the newly available source of additional expert information on medicolegal questions. The fact that the large group of so-called sudden deaths from natural causes was closely scrutinized by alert medical officers contributed much to mutual esteem.

Since in Maryland the tenure of office of a state's attorney ends after two years and since he cannot be nominated for consecutive reelection, the medical examiner in his work has to deal with several incumbents of the prosecuting attorney's office. This, as well as points of common interests with possible ensuing friction, make tact, discretion and reserve an absolute must in the discharge of the medical examiner's duties, the more so since he deals also with a somewhat fluctuating group of persons who serve as sheriffs, deputy sheriffs and county and city investigators (detectives). Without being in any clearly defined official relationship to the officers of these law enforcement agencies, the medical examiner needs their whole-hearted cooperation. Without it all his endeavors to render good service to the public would be frustrated. Fortunately, there has been no lack of zeal, understanding and helpfulness among the group of men to whom these special duties were delegated directly by the electorate or by their respective superiors in office.

The medicolegal autopsy turned out to be the most controversial subject of the new law. There were no objections against postmortem examinations in cases of obvious homicide or manslaughter. But it took some time until the public, the law enforcing agencies and the county commissioners came to the conclusion that in having these autopsies performed a distinct service was rendered to the community. In a special meeting before the board of county commis-

2. Raab, W.: Sudden Death of a Young Athlete with an Excessive Concentration of an Epinephrine-like Substance in the Heart Muscle. *Arch. Path.* 36: 383 (Oct.) 1943.

sioners, the medical examiner and the legal pathologist were given an opportunity to expound their opinions. They were able to explain why, for example, in sudden deaths in railroad yards or in municipal buildings or in certain cases of accidental death, postmortem findings would forestall a future lawsuit with eventually much greater expense to the county. The two physicians were supported in their reasoning by the state's attorney and the board's own legal adviser. A further point of interest to the county commissioners was the proof presented from available data not only that a number of examinations had been done for the county without charge but that in other cases bills had been presented only after the necropsies had established beyond doubt that there was public interest at stake.

The difficulties just described were to be expected when the new medical examiner's law was enacted in 1939. As a matter of fact the anticipation of these and similar obstacles on the part of the law makers and medical advisers was one of the main reasons that considerable leeway was left to the local deputy medical examiners. Because of the elasticity of interpretation permitted by the law, it has been possible to proceed slowly and to accustom the authorities and the general public gradually to the new situation without major conflict.

The discussion of the autopsy problem has to consider, in addition to the points touched on, the practical value to the public of postmortem examinations. No words need be wasted on cases of unequivocal criminal violence. Less well recognized by the local authorities, however, is the eventual importance of an autopsy in every case of accidental death. In cases of this type, if the cause of death can be established beyond any reasonable doubt, tedious and costly litigation at a later date may be avoided. When the argument of accident due to some primary bodily ailment (cerebral hemorrhage, coronary occlusion or others) may come up, brought to the fore in honest conviction or in hope of monetary gain, a necropsy performed shortly after death acts as an effective deterrent.

In the period covered by this report the medical examiner has been instrumental several times in contributing to the elucidation of certain public health puzzles. One autopsy of an old man who died shortly after admission to the hospital revealed as cause of death the presence of typhoid (perforated ulcer of the ileum with secondary peritonitis). This led to the discovery of a small, hitherto unknown, endemic focus of typhoid in an outlying district of the county. Another necropsy, performed on a young infant, called attention of the health authorities to a likewise limited endemic outbreak of meningococcic meningitis. The little girl showed a typical Waterhouse-Friderichsen syndrome as it has been again recently described by Martland³ in its medicolegal implications.

In a third case a sudden death was found to have been due to a foudroyant laryngeal diphtheria in one of the poorest hill sections of the county. The child, one of a family of eight, was never seen or treated by a physician. A spread of the diphtheria was prevented.

In the fourth case, a Negro aged 40 died suddenly in the county jail, where he was awaiting removal to a mental institution after having been confined originally on a count of disorderly conduct. Necropsy revealed that in spite of a negative serologic reaction

of the blood his fatal illness turned out to have been dementia paralytica with *Treponema pallidum* demonstrable in Levaditi stained brain sections.

SUMMARY.

1. In a semirural county of Maryland, 420 medical examiners' cases have been handled during the first five years period of a new medical examiner's system introduced in 1939.
2. Under this new, nonpolitical, setup a much greater case load has been carried at lower expenses for the county than under the previous, outdated coroner's system.
3. In 83 instances autopsies have been performed. These were ordered by the deputy medical examiner 49 times, whereas 34 postmortem examinations have been done with his consent but without compensation on the part of the county.
4. The exact cause of death could be established in all but 2 cases.
5. Among the 83 autopsies, 1 case of criminologic importance, due to unusual circumstances, and 3 cases of epidemiologic (public health) significance have been encountered and brought to a satisfactory solution.

BLAST CONCUSSION INJURY

LIEUT. COL. DAVID WOOLFOLK BARROW

AND

CAPTAIN HARMON T. RHOADS

MEDICAL CORPS, ARMY OF THE UNITED STATES

Two hundred persons exposed to the effects of air blast produced by high explosives have been studied. Adequate clinical facilities were available and the injuries were not complicated by flying splinters, so that an unusual opportunity was presented to study the effects of blast concussion on human beings. Complete follow-up studies have been possible.

A correlation of the position of the men in relation to the explosive charge with the injuries sustained is of considerable interest. As was to be anticipated, the closer the individual to the explosion, the greater the injury. This was not always true, however, for bizarre effects were noted. One fortunate man who was standing between 2 men fatally injured, 1 of whom was found 42 feet from his original position, escaped uninjured except for perforations of the tympanic membranes. Another man was thrown 15 feet and turned completely around in midair and yet had minor injuries. This capriciousness of injury was evident time and again. One person would be seriously injured and his neighbor with seemingly identical protection, or lack of it, would escape without damage. One soldier was resting his chin on the shoulder of another in front of him who was literally "blown to bits" and escaped with a fractured maxilla. It was evident that those standing in the front row were most seriously injured, and one row of men between the soldiers and the blast afforded protection except for the tympanic membrane. But again there were exceptions, for one man standing in the second row 30 feet from the explosion was unconscious for one hour, while his companions were hardly injured. These phenomena are presumably related to two characteristics of blast waves. In the first place, near the source the blast wave is irregular in outline¹ with many "eddies" in its periphery, and

3. Martland, H. S.: Fulminating Meningococcic Infection with Bilateral Massive Adrenal Hemorrhage (The Waterhouse-Friderichsen Syndrome). *Arch. Path.* 37: 147 (Feb.) 1944.

1. Discussion on Problem of Blast Injuries, *Proc. Roy. Soc. Med.* 34: 171-192, 1941.

a man sheltered in such an eddy might escape serious damage. In the second place, blast waves, like sound waves, are reflected from surface to surface and are subject to reinforcement or neutralization on meeting a similar wave in the same or opposite phase.² And this neutralization may explain why 1 man is seriously injured and another near him is not. Indeed, in Madrid destruction of alternate houses on opposite sides of the street was not uncommon. Since pressures vary as the square or cube of the distance from the source, this difference in critical pressures may be represented by a few feet.³

The most striking clinical feature of those who survived was a pronounced decrease in psychomotor activity.⁴ These patients were listless and apathetic, and they seemed overcome with fatigue and lassitude. They were content to stay in one place, made no conversation among themselves, and made but few demands on their attendants. There was no complaining or crying out with pain; they did not request water or sedation. Verily they were men "stunned and stupefied."

Vital functions were depressed; shock was universal and was associated with pallor and sweating. Blood pressure readings of 80 to 90 mm. of mercury systolic and 40 to 50 diastolic were the rule. This hypotension responded promptly to the intravenous administration of plasma and had entirely disappeared in every instance within twelve hours of admission. To our surprise the pulse rate in the first twelve hours was less than 60 per minute in 26 per cent, less than 70 in 75 per cent and less than 80 in 92 per cent. In addition to this unanticipated bradycardia the peripheral pulse was of a striking character, soft, collapsing and readily compressible.⁵ It was so distinctive as to be remarked on by several different medical officers. Electrocardiography showed low voltage, a flattened QRS complex and normal sinus rhythm. Arrhythmia or fibrillation was not present.

The initial temperature on admission was slightly subnormal in the majority of the patients. A secondary rise of 1 or 2 degrees in from four to twelve hours was observed in the more seriously injured, and this fever persisted for one or two days. The maximum temperature observed was 102.4 F. in the patient with abdominal distention. This fever appeared within eight hours of injury and subsided in the course of three days. The red, white and differential blood counts were within the normal range. The respiratory rate on admission was low. Slow, shallow, sighing respiration seemed characteristic but in certain individuals seemed modified by pain, and these "gasped" for breath.

Pulmonary lesions have been reported constantly in experimental animals and in human beings exposed to blast.⁶ Deep hemorrhages adjacent to the bronchi and lacerations along the lines of the ribs, and "red hepatization" associated with cyanosis, dyspnea, cough, hemoptysis and roentgen ray evidence of patchy consolidation have been prominent features of the reports of others.⁷ Pneumonia has been a common

sequel.⁸ Chest conditions in our patients were less severe. Eight patients complained of mild pain in the chest lasting more than twenty-four hours, and 1 patient had severe pain in the chest lasting for ten days. No fractures of the ribs could be demonstrated by roentgen ray, and the pain was more diffuse in nature than that usually associated with such fractures. Only 1 patient exhibited the rusty sputum and patchy consolidation reported by others. Pulmonary edema and secondary cardiorespiratory embarrassment did not develop, which may have been due to the entire absence of exertion.⁸

In experimental animals exposed to blast, hemorrhage in the subserosa of the small or large intestine in patches or annular bands has been noted. And numerous reports of intra-abdominal injury associated with immersion blast injury have appeared.⁹ But in these patients abdominal pain was not frequent in those who survived. Of those who died, abdominal evisceration was noted in 3. Severe abdominal pain was encountered in 5 instances, and mild abdominal pain in several additional patients. It was colicky and gripping in nature and associated with hyperactive peristalsis in 4 of these 5. This pain subsided in a few hours except in the patient most severely injured, who had all the signs and symptoms associated with an adynamic ileus. He exhibited diffuse abdominal tenderness, distention and absence of peristaltic sounds. Because of associated injuries, laparotomy was not feasible, and the patient's symptoms subsided in four or five days on conservative treatment. Perforation of the intestine in patients who are not killed instantly by air concussion blast must be very rare,¹⁰ and since surgery for such patients is hazardous in patients suffering from air concussion injury, laparotomy should be undertaken only with reluctance.¹¹ Let us repeat, this is very different from the conditions which pertain in immersion blast injury.

Unconsciousness of short duration was experienced by less than 20 per cent of the nonfatally injured. Two patients were unconscious for periods of three and four hours, respectively, without residual effects. Tremor, such as that sometimes associated with intense emotion, was common at the time of admission in conscious patients. One patient showed convulsive twitchings, while unconscious, and later recovered completely. In 2 of the 3 patients who died within thirty minutes after the explosion without external evidence of injury, generalized convulsions were noted. They were not unlike those sometimes associated with anoxia during anesthesia or too many "G's." Memory for events leading up to and after their period of unconsciousness was excellent. Residual paralysis did not occur. The presence or absence of permanent cerebral damage cannot be evaluated, for no psychologic studies of these individuals prior to their injury is available. Certain of these men have continued to have complaints for which no organic basis can be found, but their number and variety is no different from that encountered in other units of similar size and composition. Change in mood and psychomotor activity evident immediately after the blast did not persist.

Because of the character of the soil, multiple foreign bodies (sand) in the skin were almost universal; and for the same reason injury by fragments was absent. In most instances the particles of sand were so deeply embedded that their removal was impossible even by the most vigorous scrubbing.

Injury to eyes and ears was the most common injury encountered. Tinnitus, deafness and pain referred to the ears was almost universal immediately after the explosion. The pain and tinnitus subsided in a few hours in most instances, but partial deafness persisted. The more severe immediate deafness was associated with hemotympanum rather than perforation of the drum. In the patients with actual hemorrhage into the ear drum, usually in the region of the umbo and the handle of the malleus, there was almost complete deafness. Recovery in this group was rapid with but little impairment after two weeks.

Thirty-two patients had perforation of the ear drum (14 bilateral, 12 right ear only, 6 left ear only) varying in size from small slits to complete loss of the entire tympanic membrane and ossicles, which showed no signs of healing. It was interesting to note that there was no wax in the external auditory canals of those having perforation of the ear drums. This evidence has been used by others to show that wax has protective value. It seems to us, however, that it may simply indicate that the damage is done by the short concussive blast (0.006 second) and the detritus is removed by the longer suction wave (0.03 second). We were unable to find parts of the tympanic membrane or middle ear ossicles by the most careful examination in those patients with complete loss of both structures.

The smaller perforations, including several of more than 2 millimeters in diameter, healed rapidly. Three patients in whom slightly more than one third of the tympanic membrane was destroyed healed almost completely. Those patients in whom more than one half of the ear drum had been destroyed showed no tendency toward healing.

There was no relationship between the size of the perforation and the amount of hearing loss either immediately after the accident or five months later when a loss of approximately one third for whispered voice and a greater loss for the notes above 4,096 double vibrations on the audiogram was noted. In the 3 patients with persistent otitis media there was greater impairment in hearing. In no instance was the loss so great as to prevent the performance of military duty.

With 3 exceptions the middle ears remained unaffected during the more than six months they have been under observation, and these dried up following systemic administration of sulfathiazole. One patient had a preexisting chronic otitis media which apparently was aggravated by the blast. There was no mastoiditis in this group of patients, which we attribute to the absence of local treatment within the ears and the absence of insufflation. Bleeding from the middle ear did not occur. No patient showed signs of labyrinthine involvement such as vertigo, nystagmus, past pointing or actual falling.

Ocular symptoms were equally widespread. Almost all persons exposed to the blast complained of photophobia, blepharitis and lacrimation of varying severity. This was of limited duration with the exception of 1 patient, who continues to complain of photophobia and blepharitis after six months. One patient developed haziness of the corneal epithelium a few days after

injury, which disappeared in a week. In addition to those patients whose eyes were injured by blast concussion alone there were 31 patients with foreign bodies in the eyes. They were lodged in the corneal epithelium and conjunctiva in 20 patients, deep in the cornea in 9 patients and in the anterior lens capsule in 2 patients. Three patients exhibited subconjunctival hemorrhage without foreign bodies. There were no patients in this group with hemorrhage into the anterior or posterior chambers or in the retrobulbar region. There were no patients with detachment of the retina.

Six months after injury 1 patient has light perception only, 1 patient is blind in one eye and 1 patient has a posterior synechia with pronounced impairment of vision in that eye. These patients suffered from ulceration of the cornea which eventually healed. Nine men developed corneal opacities of varying size.

That tremendous damage can be accomplished alone by blast can scarcely be questioned. Death was instantaneous in most instances in which it occurred and was usually due to multiple injuries. In only 3 instances was it unaccompanied by single or multiple fractures and/or evisceration of a body cavity.

The prognosis in those not killed more or less instantaneously is probably more directly related to the treatment given than to any other single factor. The underlying pathologic lesion is probably associated with hemorrhage into various tissues and any activity, even that of transporting a patient, seems to increase this hemorrhage and lessen the likelihood of survival. Indeed, it is believed that hemorrhage into the pulmonary parenchyma may continue for more than two days, and transfer of even seemingly well patients during this interval is hazardous.⁸ All patients in this group survived who reached the hospital alive or, to put it differently, all patients in this group who survived the effect of blast concussion by sixty minutes were saved.

Treatment is symptomatic and is largely governed by individual indications. Plasma may be used in liberal amounts for every patient with signs of shock and repeated as long as hypotension persists. Oxygen was likewise given freely to those patients who were either in shock or who had pain in the chest or respiratory embarrassment. Sulfonamide drugs were administered prophylactically to all patients with perforations of the ear drums or persistent pain in the chest.

SUMMARY

1. Detailed observations and complete follow-up studies were made on a group of 200 men exposed to "blast" due to the detonation of high explosives.

2. Those nearest the explosion were, in general, most seriously injured, but capricious choice of victim was noticeable.

3. Death was almost instantaneous when it occurred and was due to multiple injuries in most instances.

4. Those patients who survived sixty minutes recovered.

5. Damage to the ears by blast and to the eyes from foreign bodies occurred in a high percentage of those who recovered. Periods of unconsciousness, convulsions, chest pain, pulmonary complications and abdominal distress were minimal in this group. Intestinal perforation did not occur. Shock, bradycardia, hypotension, decreased psychomotor activity and slow respiration were the outstanding clinical signs and symptoms of this group.

Clinical Notes, Suggestions and New Instruments

CONTACT DERMATITIS FROM PENICILLIN

MAJOR H. D. PYLE
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND

HERBERT RATTNER, M.D.
CHICAGO

In November 1943 a penicillin section was established at the Gardiner General Hospital. The medical officer in charge, who undertook to prepare the various solutions as well as to administer the drug to patients, noted shortly thereafter that he had a mild marginal blepharitis and conjunctivitis with some blurring of vision on reading. Glasses were prescribed for the condition, but the blepharitis persisted and soon there developed a dermatitis which began on the bridge of the nose and spread to involve adjacent areas of the forehead and the central oval of the face. The eruption had the characteristics of a relatively acute dermatitis due to contact with an irritant, and its source was thought to be in the plastic frames of the newly acquired glasses.

These glasses were discarded, but the dermatitis became progressively worse despite topical treatment with bland preparations, and in the course of a few weeks similar eczematous lesions appeared on the dorsal surfaces of the third, fourth and fifth fingers of the left hand and the distal third of the penis. The latter was swollen, edematous, reddened and excoriated, and in areas the dermatitis was moist. On Jan. 15, 1944 the actual handling of the penicillin was delegated to an assistant, and in the course of the following two weeks the lesions had completely disappeared. Some time later, when the services of the assistant were not available for a period of forty-eight hours, it again became necessary for the first officer to handle the penicillin solutions, and within twenty-four hours there was a recurrence of the dermatitis affecting the same areas.

When this attack had completely subsided, a closed patch test was performed on the arm with the penicillin in the form in which it was used. The patch was removed after forty-eight hours, and at seventy-two hours there was a strongly positive reaction with itching, erythema and vesiculation. The site showed residual hyperpigmentation even four weeks later.

We were informed by a firm that is producing penicillin "The mold in growing on this medium produces a number of substances in addition to penicillin, and as the purification process at present utilized results in a content of penicillin varying between 20 to 40 per cent, the remaining material consists of extractives soluble in organic solvents which occasionally produce urticaria and vary from batch to batch of the material." Therefore it seemed important to determine whether the mold itself or the medium was the source of the irritation. Patch tests were then performed, one with the medium alone and another with the penicillin as it is used, the latter to serve merely as a check on the first test. The whole product again produced a strong reaction, but there was no reaction from the medium, which consisted of corn steep liquor and a small amount of lactose. Another patch test was then performed with the purest penicillin then available, the material from which the crystalline product is made, and this too gave a slightly positive reaction. Several weeks later we obtained some of the crystalline material, and this, when dissolved in water and tested by means of a closed patch test, also gave a strongly positive erythematovesicular reaction. It was therefore concluded that the dermatitis in this case was produced by the penicillin itself.

For the past eight weeks the penicillin has been handled by three hospital corps men. All three have experienced, at times,

slight discomfort from itching of the face and penis, though they showed no evidence of dermatitis—their symptoms were discovered only after pointed interrogation. None of these men had ever before had eczema or any other disease of an allergic nature. The question was then raised as to whether the reaction was in the nature of a true allergic hypersensitivity or a "chemical irritation." There was, of course, no material available for patch test studies of a large group of normal subjects; however, penicillin has been applied frequently in the form of dressings for topical therapy on several patients, and in none of them was there any evidence of irritation of the skin from it.

SUMMARY

A case was observed of dermatitis venenata of the face and genitalia from contact with penicillin. This is apparently the first such case to be reported.

1660 East Hyde Park Boulevard—25 East Washington Street.

HOW TO AVOID FLARE-UPS OF PEPTIC ULCER

WALTER C. ALVAREZ, M.D., ROCHESTER, MINN.

A man of 50 who had always been well discovered one day that the man who for twenty years had been his brother-in-law, his closest friend and his business partner had been falsifying the books in order to steal from him. All that night he lay awake in great mental distress, and next day he had a big gastric hemorrhage. Another man, a physician, after examining a woman's stomach with a roentgenoscope, discovered that he had used a current of 60 milliamperes instead of the usual 3 milliamperes. After lying awake all night worrying over the expected burn and resultant damage suit he found himself almost incapacitated by the pain of a bad ulcer. Another man, when a violent strike in his factory distressed him terribly, had a big hemorrhage. A woman who adored her peppery little daughter-in-law one day inadvertently offended her and brought down on her head a storm of abuse which nearly killed her. Next day a long-healed ulcer flared up and perforated. A woman who heard that her soldier husband had just been killed at the front promptly had a hemorrhage.

Many such experiences will doubtless spring to the mind of every busy physician who reads these words, all illustrating what is well known today, namely that the patient with ulcer is most in danger of a flare-up or a catastrophe during the hours immediately following a distressing emotional storm. Then is the time when, probably with an increase in the acid gastric secretion, and perhaps a decrease in the alkaline and neutralizing secretions that flow into the duodenum, or a combination of these two processes, the acidity of the contents of the first portion of the duodenum becomes so high that an ulcer either develops or, if present already, promptly becomes greatly deepened. As Wolf and Wolff showed in their patient with a gastric fistula, psychic strain can produce turgescence of the gastric mucosa with a great increase in the acidity of the gastric juice.

Under the circumstances it would seem obvious that the time to start strenuous treatment should always be immediately after a psychic strain has come. Why should one wait until an ulcer has formed or, if present, has eaten its way into a blood vessel or clear through the wall of the intestine? Why wait for disaster when it might perhaps be headed off and prevented?

Furthermore, since it now appears probable that most of the injury to the duodenal mucosa that is wrought by acid comes during those hours between 10 p. m. and 3 a. m., when, in the person with an ulcer temperament, the stomach tends to be empty of food but full of highly acid and unbuffered gastric juice, would it not be logical the evening after a nervous crisis has occurred to begin with either a constant antacid drip or the taking of food and antacids every one or two hours from dinner time on to 2 or 3 a. m.? The patient can easily set an alarm clock to wake himself perhaps at midnight and again at 2 a. m.

From the Gardiner General Hospital, Chicago.
Dr. Rattner is volunteer civilian consultant in dermatology to the Gardiner General Hospital.

From the Division of Medicine, Mayo Clinic.

For some years now I have been asking my patients with ulcer to do just this, and already some feel that the treatment has tided them over some bad crises in their lives and kept them from having a flare-up of their ulcer. Dozens of physicians with a tractable type of ulcer have told me that during the intervals in which their life goes peacefully they do not seem to need much dieting or other treatment.

SUMMARY

It is suggested that when a patient who has had an ulcer goes through an emotional crisis he should immediately start taking food every hour or two. He shouldn't wait for the expected flare-up or hemorrhage or perforation. The extra feedings are probably most needed between the hours of 10 p. m. and 3 a. m.

SCHISTOSOMIASIS MANSONI

MICHAEL P. DI GIACOMO, M.D., AND ROBERT A. MAYER, M.D.
Passed Assistant Surgeons (R), United States Public Health Service
ELLIS ISLAND, N. Y.

Schistosomiasis *mansoni* infection is an acute or chronic disease caused by the blood fluke *Schistosoma mansoni*. The adult worms live and lay their eggs in the veins draining the colon, the rectum and occasionally the bladder. When the ova are deposited in fresh water the egg hatches and the embryo (miracidium) enters a snail, the intermediate host (genus *Planorbis* or *Australorbis*), where it undergoes asexual development. The free swimming larvae (cercariae) emerge from the molluscan host into fresh water and infect man by penetration of the skin during swimming, wading, bathing or using infected water in showers.¹

The diagnosis is established only when the characteristic lateral-spined ova are found in the stool. Occasionally they are present in both urine and stool.

Antimony and arsenical compounds are used in the treatment of *Schistosomiasis mansoni*. The trivalent antimony compound neoantimosan (Fuadin) is one of the drugs of choice because of its ease of administration and infrequent reactions. Potassium or sodium antimony tartrate is administered when satisfactory results are not achieved after the use of fuadin.²

REPORT OF CASES

CASE 1.—An Arab aged 30 (from Yemen) was admitted to the U. S. Marine Hospital, Ellis Island, N. Y., on Sept. 29, 1943 complaining of weakness, loss of weight, poor appetite, constipation, and blood and mucus in the stools.

The onset of his complaints began about one year prior to admission, when he had abdominal cramps and a small amount of blood and mucus in the stools. About six months prior to admission constipation started, and he had burning on urination and blood in the urine, the blood being expressed at the end of micturition. About five months prior to admission the patient suddenly felt itchy and had a generalized skin eruption, which he described as resembling hives. The eruption lasted for about two days and then disappeared. A week later it recurred and for the next two months it appeared intermittently. The patient stated that he had not had any previous illnesses except an attack of chills and fever lasting about a month, which occurred five years previously, while he was living in Yemen.

Physical examination at the time of admission was normal except for malnutrition. The patient was 64 inches (163 cm.) tall and weighed 112 pounds (51 Kg.). No rectal polyps or hemorrhoids were present. Several small, irregularly shaped, bleeding, ulcerated areas above the distal rectal haustation

were seen on proctoscopy. No ova or parasites were found in scrapings taken from the ulcerated areas. Repeated stool examinations showed the presence of ova of *Schistosoma mansoni* and *Trichuris trichiura*. Centrifuged specimens of urine did not contain any ova or parasites. The red blood cell count was 4,920,000, with 85 per cent hemoglobin (Sahli), and the white blood cell count was 5,400, with 65 per cent neutrophils, 30 per cent lymphocytes and 5 per cent eosinophils. The Wassermann and Kahn reactions were negative, and the sedimentation rate (Cutler method) was 6 mm. in one hour. The total blood protein was 6.2 per cent, with an albumin of 3.5 per cent and globulin of 2.69 per cent, yielding an albumin-globulin ratio of 1.3. A roentgenogram of the chest was normal.

Treatment consisted of a full course of ten intramuscular injections of fuadin and 1.0 Gm. of hexylresorcinol was given orally for his *Trichuris trichiura*. This was combined with general supportive measures including a high caloric, high vitamin diet. Using zinc flotation technic, no ova of *Schistosoma mansoni* or *Trichuris trichiura* could be found after the fourth injection of fuadin, and repeated examinations remained negative. The patient's appetite improved, he gained strength, and there was no more blood or mucus in the stools. At the time of discharge, on Dec. 14, 1943, one month after discontinuing treatment, he had gained 3 pounds (1.3 Kg.).

CASE 2.—An Arab aged 30 (from Yemen), who has lived in the United States for the past twenty years, was admitted to the U. S. Marine Hospital, Ellis Island, N. Y., on Oct. 25, 1943 complaining of low back pains, weakness, and some loss of weight for the past two years. Treatment at several hospitals for lumbosacral strain, consisting of alcohol injections in the lumbar region and short wave diathermy to the back, was given, but he failed to improve. The patient stated that he had always been well previous to the onset of his illness.

Physical examination at the time of admission was normal, except for moderate tenderness elicited on pressure over the lumbosacral region and over both iliac crests posteriorly. The patient was 66 inches (167 cm.) tall and weighed 132 pounds (60 Kg.). The red blood cell count was 4,110,000, with 88 per cent hemoglobin (Sahli), and the white blood cell count was 4,200, with 58 per cent lymphocytes, 34 per cent neutrophils and 8 per cent eosinophils. The Wassermann and Kahn reactions were negative and the sedimentation rate (Cutler method) was 24 mm. in one hour. Roentgenograms of the spine, long bones and chest were normal. Ova of *Schistosoma mansoni* were found in the stool on three successive days. Centrifuged specimens of urine did not contain any ova or parasites.

The patient was given a full course of fuadin intramuscularly. With the zinc flotation technic, ova could not be found after the fifth injection and the stools remained negative.

At the time of discharge on Jan. 3, 1944, one month after discontinuing treatment, the patient had gained 13 pounds (5.9 Kg.), his backache had almost completely subsided, and he felt very much improved. The red blood cell count was 4,810,000, with 86 per cent hemoglobin (Sahli), and the white blood cell count was 7,200, with 70 per cent neutrophils, 27 per cent lymphocytes and 3 per cent eosinophils. The sedimentation rate (Cutler method) was 18 mm. in one hour.

COMMENT

These 2 cases of *Schistosomiasis mansoni* demonstrate the insidiousness of the disease. This point was well demonstrated by the second patient, who had been living in this country for twenty years. His infection began, in all probability, prior to his entry into the United States.

Physicians should be constantly on the lookout for parasitic diseases, especially in all persons returning from endemic areas. It is therefore advisable for every one who has been in any country where parasitic diseases exist to have a stool examination on returning to this country. The stools should always be obtained following the administration of a saline purge. The examination should be made regardless of whether or not symptoms of a parasitic infection are present.

AMERICAN HEALTH RESORTS

THE PLACE OF HEALTH RESORTS IN REHABILITATION FOLLOW- ING INJURIES

FRANK H. KRUSEN, M.D.
ROCHESTER, MINN.

It is undoubtedly a fact that we are now facing the most stupendous problem in rehabilitation which has ever existed in the history of the world.¹

The number of war injuries sustained in the army and navy and also in industrial and other civilian pursuits will be the largest our country has ever known. Adequate utilization of our national health resorts will assist materially in solving our rehabilitation problems. But rehabilitation of those disabled by the war must follow a broad general plan in which use of our health resorts can play only a limited, although extremely important, part.

Fortunately, considerable thought is already being given to postwar rehabilitation. President Roosevelt² in a radio address on July 28, 1943 said: "We must this time have plans ready—instead of waiting to do a hasty, inefficient and ill considered job at the last moment." He outlined a six point program, which included as one item "improved and liberalized provisions for hospitalization, rehabilitation and medical care of disabled members of the armed forces and merchant marine." Former President Herbert Hoover³ has said "I have always felt it of paramount concern to rehabilitate human beings; to return a man or woman to productive citizenry is an urgent need and a service of the highest order to the social and economic welfare of our country."

General Fred W. Rankin⁴ in his presidential address to the American Medical Association said "Consideration is already being given to postwar planning even though it may seem little warranted at this time. It should be realized, however, that only by such long range charting can the confusion and disorder which characterize immediate postwar reconstruction periods be averted." During the last war, as hinted by President Roosevelt, some of our rehabilitation planning was hasty and inefficient. This led Johnstone⁵ to comment "Rehabilitation of our armed forces has been attempted following all previous wars but has never been successful." General Frank T. Hines,⁶ administrator of the Veterans Administration, has explained that after the last war "veterans were advised to undertake a training program for an objective which could not be obtained."

It is evident that disabled persons must be restored as nearly to normal as possible before they are returned to civilian occupations. They cannot attain suitable

adjustment in normal activities without first receiving adequate medical reconstruction. Now is the time for us to determine just exactly what is the place of health resorts and other rehabilitation agencies in this reconstruction of the injured. Health resorts often will be found to be ideal locations for providing satisfactory "rehabilitation and medical care" in order to return injured persons to "productive citizenry."

GENERAL PLAN FOR REHABILITATION

In order to determine the exact sphere of usefulness of treatment in a health resort as part of a broad plan of total rehabilitation, it is necessary to outline such a plan. Recently I¹ pointed out that our problem begins when a soldier or sailor is first wounded and ends only when he is finally completely adjusted in a suitable position in civil life. Similarly, the civilian war worker who is injured must be carried through several stages of reconstruction before he is finally completely rehabilitated. I have concluded¹ that there are, roughly, nine steps to be taken in a complete plan for total rehabilitation. These are:

1. Immediate emergency care.
2. Secondary emergency care.
3. Care during transportation
4. General hospital care.
5. Care in rehabilitation centers.
6. Vocational guidance.
7. Vocational training.
8. Selective placement.
9. Industrial rehabilitation.

It is during steps 5, 6 and 7 that health resorts will be utilized most frequently. They should serve chiefly as rehabilitation centers, and during the reconstruction period vocational guidance and vocational training often can be inaugurated. In some instances the health resort can fit also into steps 4 and 8 of the overall rehabilitation plan. At times general hospitals can be located at health resorts in order that patients may be placed in a healthful environment at the earliest possible moment. Also at times selective placement can be arranged at the health resort before the patient establishes a permanent home in civil life. It is obvious that in many instances it will be advisable for the disabled person to be placed suitably before he leaves the rehabilitation center. In the overall plan of rehabilitation which we must develop it is evident that health resorts may have a wide sphere of usefulness.

BRITISH PLANS FOR REHABILITATION

In the present war in England there has been promulgated the Tomlinson plan.⁷ This is essentially an elaboration of the medical rehabilitation program developed at Shepherd's Bush in 1916 by Sir Robert Jones.⁸ In an appendix to the Tomlinson report appears a "rehabilitation scheme." In this scheme are listed the various types of disablement, the types of institutions in which these conditions should be treated, the suggested remedial treatment, the probable resulting medical condition, the further provisions which are needed, and also the type of center or institution in which final rehabilitation should be completed. It will be seen on consulting the accompanying table that physical therapy, occupational therapy, physical training, vocational training centers, sheltered workshops and reconditioning centers (with medical supervision) are recommended

for many types of disablement. These forms of therapy usually can be provided best at an established health resort.

The actual experiences of the British Royal Air Force with rehabilitation centers of the health resort

Royal Air Force, that they will be quoted at some length. Watson Jones mentioned an air gunner who remained in a civilian orthopedic hospital for treatment of a torn and displaced semilunar cartilage for ten months and who was still totally incapacitated even

REHABILITATION SCHEME FOR VARIOUS TYPES OF DISABLEMENT
(BEING THE APPENDIX TO THE TOMLINSON REPORT)

I.—Type of disablement.	II.—Type of institution in which treated.	III.—Remedial treatment.	IV.—Resulting medical condition.	V.—Further provision needed.	VI.—Type of centre or institution.
1. Fracture or other physical injury.	Orthopedic centre. Fracture unit. General hospital.	Surgical or orthopedic. Occupational therapy. Remedial exercises and physiotherapy. Hospital workshops.	(a) Complete restoration. (b) Partial restoration—but allowing return to ordinary (c) ment in a new occupation—after training if necessary. (d) Permanent and serious disability causing a grave handicap to employment and, in some cases, preventing employment under ordinary conditions.	(a) In some cases reconditioning course. (b) Ditto. Vocational training preceded in some cases by a reconditioning course. (d) Specialised vocational training or sheltered employment. Note.—Artificial limbs may be required for some cases under (c) and (d).	(a) Reconditioning centre. (b) Ditto. (c) Vocational training centre—after (for some cases) a preliminary course at a reconditioning centre. (d) Special training centre for ordinary employment. Institution providing sheltered employment.
2. Othersurgical conditions and the general group of medical cases.	As a rule in a general hospital. (Note.—The present provision for proper rehabilitation treatment is inadequate and should be developed.)	If illness is prolonged, and especially if associated with sepsis, gradual restoration of bodily strength by physiotherapy, exercises, &c., would be essential—with special attention to the feet to prevent dropping of the arches.	(a) The majority should have complete restoration of (b) Convalescent treatment—followed in some cases by a reconditioning course—under medical supervision. Note.—Artificial limbs may be required for some cases.	(a) In some cases a reconditioning course. (b) Convalescent treatment—followed in some cases by a reconditioning course—under medical supervision. Note.—Artificial limbs may be required for some cases.	(a) Reconditioning centre. (b) Reconditioning centre—with medical supervision.
3. Cardiac cases.	General hospital. (Note.—Special hospitals are required for the further treatment of some of the cases in this group.)	If the valves are badly affected, little chance of restoration. Where the heart muscle only is involved, restoration to fair, if not full, working capacity can be achieved—by rest over a long period and then graduated exercises.	(a) Residual disability preventing heavy physical activity but permitting light and sedentary work. (b) Serious disability preventing employment under ordinary conditions.	(a) Special care in selecting employment—with vocational training as required. (b) Sheltered employment.	(a) Vocational training centre as necessary. (b) Institution providing sheltered employment. Note.—Medical supervision will be necessary under both (a) and (b).
4. Pulmonary tuberculosis.	Sanatorium. Tuberculosis hospital. Sanatorium-hospital. Home for advanced cases.	Rest, hygiene, diet. Collapse therapy (including major surgery). Chemotherapy. Occupational therapy.	(a) Restoration—permitting employment under ordinary conditions. (b) Quiescence—requiring part-time or modified employment to prevent relapse. (c) Unfit for employment under ordinary conditions	(a) Care in selecting employment. (b) Special provision for part-time or modified work. (c) Sheltered employment.	(a) — (b) For some cases—special institution providing sheltered employment. (c) Special institution providing sheltered employment.
5. Blindness.	Special eye hospital. Special department of general hospital. General hospital for treatment of underlying medical condition.	Surgical (e.g., cataract removal). Optical appliances, including recent "contact lenses." General medical treatment.	(a) Restoration of good sight. (b) Restoration of limited but useful sight. (c) Blindness or its near equivalent.	(a) In some cases a reconditioning course. (b) Care in selecting employment and, for some cases, vocational training. (c) Carefully selected employment in ordinary industry, or sheltered employment.	(a) Reconditioning centre. (b) Vocational training centre as required. (c) Blind workshop or organised home worker scheme.
6. Deafness.	Special department of general hospital. General hospital for treatment of underlying medical condition.	Surgical. General medical treatment. Appliances.	(a) Improvement of hearing. (b) Defective hearing. (c) Total deafness.	(a) — (b) Training in lip reading or provision of artificial aid. (c) Training in lip reading and, for some cases, vocational training.	(a) Vocational training centre as necessary. (b) Schools or evening institutes, and, for some cases, vocational training centre.
7. Neurosis.	Neurosis centre (under E.H. scheme). Special O.P. department of general hospitals. A few special clinics for outpatients.	Psychotherapy, with occupational therapy, physical training and workshops.	(a) Restoration—permitting return to ordinary employment. (b) Minority remain as problem employment.	(a) Careful selection of employment—with a reconditioning course for some cases. (b) Selected employment and aftercare.	(a) For some cases—reconditioning centre. (b) —
8. Psychosis.	Mental hospital—as certified or voluntary patients	Medical and psychotherapeutic treatment, with occupational therapy.	(a) Fit for ordinary employment. (b) Fit for specially selected employment. (c) Permanent disablement and unsuitable for employment.	(a) Assistance in placing probably preceded in some cases by a reconditioning course. (b) Carefully selected employment and aftercare. (c) —	(a) Reconditioning centre for some cases. (b) — (c) —

From the London Lancet 1:119 (Jan. 23) 1943.

type have been so enthusiastically reported by Watson Jones,⁹ civilian consultant in orthopedic surgery to the

though the diagnosis had been correct, a skilful operation had been performed, there had been no surgical complication and he was receiving daily massage. He limped, "he would not cooperate" and he was depressed.

9. Jones, R. W.: Rehabilitation in Royal Air Force, Brit. M. J. 1: 403-407 (March 28) 1942.

He had been told that "the nerve to his knee had been cut." Then he was transferred to one of the orthopedic rehabilitation centers of the Royal Air Force medical service.

Watson Jones described subsequent events as follows: "He saw the sky, the sea, the open spaces. For many months he had seen only the stone walls of many corridors. His new surroundings were different: there was a lounge and a writing room, tasteful decorations and flowers, a menu which was varied and excellent, an atmosphere of well being and contentment. After a few days he smiled. There was sometimes a sparkle in his eye. Within a week he sensed the spirit of optimism. It grew upon him and he was reassured. His difficulties were explained and he was taught special exercises. He learned to walk then to run. He became an enthusiast and worked hard. He worked in the gym, played on the fields, swam in the pool, cycled on the track. Time raced past, for he was busy. He attended lectures, played billiards and went to concerts. He became bronzed and fit. He laughed and was full of the joy of life. In seven weeks he returned to his unit and to full duty. He forgot about the 'nerve in his knee.'

"Ten months—total incapacity; seven weeks—full recovery."

What better argument could one present for the importance of the health resort in rehabilitation of the disabled? Watson Jones has stressed the fact that this is not an isolated case but is "typical of the experience of many victims of bone and joint injury."

AMERICAN PLANS FOR REHABILITATION

The British have had more time to develop rehabilitation plans and also have had more military and civilian casualties than we have had in the United States. In the course of the last war there was organized in the Office of the Surgeon General of the United States Army a Division of Physical Reconstruction. This division functioned so successfully that Cotton¹⁰ was led to comment "During the war our returning soldiers were given a care in convalescence that was wiser and broader than we have been accustomed to and was carried out with an extraordinarily high average of efficiency." But with the signing of the armistice in 1918 this reconstruction program gradually deteriorated and the final rehabilitation of many of our soldiers was not accomplished:

Unfortunately, physicians frequently have considered that their responsibility ended when the patient was dismissed from the general hospital and they have failed to carry through with the medical supervision of the last five steps of the complete nine step rehabilitation plan which was mentioned earlier in this article. Notably did we fail to establish enough well organized rehabilitation centers in which to provide physical therapy, occupational therapy, limited work therapy, sheltered employment, remedial exercises, sports and recreation similar to the modern Royal Air Force center in which the air gunner mentioned by Watson-Jones convalesced so rapidly.

In this war it is already apparent that we are doing much better. Although there is still a great deal to be accomplished, it is now evident that we are gradually developing all phases of a general rehabilitation plan.

Starting with step 4 of the nine step rehabilitation plan, general hospital care, we find that army physicians

are thinking about the provision of proper exercises in early convalescence. For example Stephens,¹¹ intrigued by the work of von Quincke¹² and Smitt,¹³ who urged early employment of exercises for hospitalized patients in the course of the last war, has stressed the need for exercise in the early stages of orthopedic convalescence. In order to encourage patients to progress with their exercises, Stephens has recommended Lieut. Col. Howard Rusk's plan for grading all cases in five categories. The patient then obtains benefit and a psychic stimulus by progressing from one grade to another. These five grades or classes are as follows: Class 5—Patients who are completely bedfast but not in critical condition. Class 4—Patients who are capable of being out of bed but are still on crutches and cannot leave the ward. Class 3—Patients who are out of bed and going to meals but not yet ready for rigorous training. Class 2—Patients who are out of bed and about, walking without assistance and who are nearly ready for duty. Class 1—Patients who are capable of exercising for at least one hour twice a day. Stephens concluded that there is need for these early physical exercises in order "to shorten the recovery period, improve morale and lessen the danger of permanent disability."

It is extremely pleasing to observe that in this war our army, navy and the Veterans Administration are establishing rehabilitation centers at many health resorts in which the exercises started in general hospitals according to Stephens' plan can be continued and in which all other forms of rehabilitation procedure can be provided.

Army Medical Centers at Health Resorts.—The United States Army Medical Corps has established, among others, hospitals at the following resorts: (1) White Sulphur Springs, W. Va., Ashford General Hospital; (2) Colorado Springs, Colo., Station Hospital, Camp Carson; (3) Denver, Fitzsimons General Hospital; (4) Hot Springs, Ark., Army and Navy General Hospital; (5) Battle Creek, Mich., Percy Jones General Hospital; (6) Swannanoa (near Asheville), N. C., Moore General Hospital; (7) Tucson, Ariz., Station Hospital, Davis-Monthan Airfield, and (8) Miami, Fla., Miami Army Air Force Hospital.

Navy Medical Centers at Health Resorts.—The Bureau of Medicine and Surgery of the United States Navy has established, among others, hospitals at the following resorts: (1) Asheville, N. C., (2) Yosemite, Calif., (3) Glenwood Springs, Colo., and (4) Sun Valley, Idaho.

Veterans Administration Centers at Health Resorts.—It is understood that the Veterans Administration is contemplating the establishment of hospitals at such health resorts as (1) Saratoga Springs, N. Y., (2) Hot Springs, Salt Lake, Utah, (3) Hot Springs, S. D., (4) Bay Pines, Fla., (5) Mineral Springs, Texas and (6) Excelsior Springs, Mo.

Representative Rehabilitation Plans Developing at Army and Navy Hospitals.—It has been my privilege to train in methods of physical rehabilitation a considerable number of the army and navy officers who are mentioned in the following paragraphs. Thus I have been able to follow with great interest the rehabilitation programs that some of these fine officers are developing. I wish that it was possible to describe all these develop-

11. Stephens, J. T.: Unpublished data.

12. von Quincke, H.: Bewegungsbildungen bei Nachbehandlung innerer Krankheiten, München, med. Wchnschr. 66: 1339-1340 (Nov.) 1919.

ments, but there is space for only a few. The rehabilitation work at Army and Navy General Hospital at Hot Springs, Ark., at Moore General Hospital, at Ashford General Hospital, at Fitzsimons General Hospital and at the Naval Convalescent Hospital at Glenwood Springs is particularly interesting and perhaps typifies

Fig 1.—Convalescent patients at Ashford General Hospital pitching horseshoes for reconditioning and recreation.

the progress in rehabilitation of the disabled which is being made at various governmental hospitals in health resorts.

Army and Navy General Hospital, Hot Springs, Ark.: The Army and Navy Hospital is an old established military hospital which has long been conducted as a rehabilitation center. It has a well organized physical therapy section which has been under direct medical supervision for many years. The last three army medical officers who have directed this department are Major Dwight Lawson, Major A. E. White and Capt. Jerome Lee. The hospital has a physical therapy department, a fever therapy department, a hydrotherapeutic pool and a heliotherapy deck. In these departments qualified technicians administer various forms of treatment under the supervision of the medical chief of the section. Before the outbreak of the present war, many chronic diseases were treated at this hospital.¹⁴ An excellent program of rehabilitation is in operation.

Moore General Hospital, Swannanoa, N. C.: The Moore General Hospital is one of the newer army hos-

Fig 2.—Convalescent patients playing tennis at Ashford General Hospital

pitals established in the beautiful mountain health resort district of western North Carolina near Asheville. The altitude is 2,700 feet above sea level. Major Earl Rothermel is in charge of physical rehabilitation at this hospital.¹⁵ A complete physical therapy department has

been organized and it is being utilized chiefly for the rehabilitation of acute injuries.

Ashford General Hospital, White Sulphur Springs, W. Va.: Just as is true of the Moore General Hospital, so the Ashford General Hospital is situated in a delightful mountainous resort region. The famous old Greenbrier Hotel has been remodeled to accommodate this hospital, and the magnificent grounds, including tennis courts, golf courses and mountain trails, are available for the convalescent soldiers.

Capt. Carl Levenson is in charge of physical rehabilitation at this hospital. The program for rehabilitation of the disabled at Ashford General Hospital is notable because Colonel Beck, the commanding officer, has established a special convalescent program. This plan is under the direction of a special service officer, Lieut. Robert E. Strzelczyk, who is a graduate in physical education and also a registered physical therapy technician.¹⁶

An individualized exercise program is provided for each patient according to his physical capabilities. Most of the convalescents are finally discharged back to duty. A sports program is provided, including fishing, lunking over the many trails, horseshoe pitching (fig. 1), tennis (fig. 2), croquet, calisthenics (fig. 3), throwing the

Fig 3.—Convalescent patients in calisthenics class at Ashford General Hospital.

medicine ball (fig. 4), golf (fig. 5), badminton (fig. 6), archery (fig. 7), volley ball and wood carving.¹⁷ With such an environment and with such a well organized program there is small wonder that our disabled soldiers are rapidly being rehabilitated at this fine institution.

Fitzsimons General Hospital, Denver: The Fitzsimons General Hospital is one of the older permanent army general hospitals. It has recently been housed in a very large and commodious new building (fig. 8). Situated at a high altitude, Denver is well known as a health resort region.

Major O. L. Huddleston¹⁸ is in charge of physical rehabilitation at this hospital. Just as the Ashford General Hospital is notable for its convalescent exercise program, so is the Fitzsimons General Hospital distinguished for the excellent convalescent ward program which has been developed by the commanding officer, General Quade, on the recommendation of Major Huddleston. These plans might well be copied by other governmental and civilian rehabilitation centers.

16 Col. Clyde M. Beck, commanding officer at the Ashford General Hospital, has recently written me as follows: "From my experience in the last war, and as a medical officer since that time, I feel that one of the greatest steps which has been taken in this war has been the effort directed toward the rehabilitation of the injured soldiers. I firmly believe that the health resort centers which are being used by the Army are playing an ever increasing part in this program."

17 Seeley, Sam. Personal communication to the author.

18 Huddleston, O. L. Personal communication to the author.

14 White, A. E.: Personal communication to the author.
15. Rothermel, E. W.: Personal communication to the author.

The convalescent ward program has been incorporated in the therapeutic plan of the physical therapy department. To begin with, Capt. John Naugle, a medical officer who had been specially trained in physical therapy, was selected as the ward officer. The administration was placed under the physical therapy department. Patients assigned to this convalescent ward no longer report to their original wards except for weekly reexamination. There is no nursing service associated with the ward. The personnel in the ward consists of enlisted men exclusively. The medical officer is assisted in the management and care of patients by several sergeants.

Convalescent care of these patients includes drill, calisthenics and gymnastic sports such as volley ball, basketball and football signal practice. The convalescent patients who require physical therapy report regularly to the physical therapy clinic for treatment. The therapeutic program is coordinated so that patients are kept busy most of the day.

When patients are assigned to the convalescent ward program they are no longer under liberal hospital regulations but under strict military discipline. Surprisingly they prefer this strict supervision and regimentation to

Fig 4—Convalescent patients throwing the medicine ball at Ashford General Hospital

the liberal and somewhat relaxed discipline of the ordinary hospital ward. Most of the patients were in the surgical service and their morale improved materially when they were transferred to the convalescent ward program. Interestingly, the patients on this program have exhibited a decided increase in the rate of progress toward recovery over the rate achieved when they were receiving only physical therapy. It is proposed to coordinate this convalescent ward plan with occupational therapy and work therapy.¹⁸ This is the type of program which undoubtedly will tend to improve morale and speed recovery.

Naval Convalescent Hospital, Glenwood Springs, Colo. (fig. 9): In the course of the last war the Medical Corps of the United States Navy did not need to develop an extensive convalescent program but, with the increased number of naval casualties in this war, the need for naval rehabilitation centers has become evident. It is very gratifying to note that the Bureau of Medicine and Surgery of the navy is aware of this need and has taken immediate steps to make satisfactory provisions for it. One of the most interesting and most complete programs for rehabilitation of the disabled sailor is being developed at Glenwood Springs. This plan is of especial interest because the natural resources of this health resort are being utilized to the fullest extent.

The program is being developed by the physical rehabilitation officer, Lieut. Glenn Drewyer, a physician with special training in physical medicine, under the direction of the commanding officer, Captain McDermott. During a period of six months of intensive training in physical medicine, Lieutenant Drewyer

Fig 5—Convalescent patients playing golf at Ashford General Hospital.

worked out a complete rehabilitation scheme for injured sailors. It is extremely gratifying to find that he is now being given the opportunity to develop this plan in a practical manner.

Attached to the hospital is "the world's largest mineral water swimming pool," which is 650 feet long by 100 feet wide. This pool is supplied by Yampah, which is the largest hot mineral spring at the resort. The temperature of the water from this spring is 127 F., but this temperature can be modified and controlled by governing the inflow to the pool from an adjacent mountain creek. Thus there is offered a tropical water swimming pool, at an elevation of 5,740 feet above sea level, which can be utilized therapeutically the year round. This pool is being employed for underwater exercises. Another spring comes from a cave in the mountainside. The Indians used to take hot vapor baths in this cave. It was called by them "Yama Water," or medicine water. Subsequently it was enlarged to include three caves, and a building was

Fig 6—Convalescent patients playing badminton at Ashford General Hospital

placed over these. In these three caverns, water from the spring at a temperature of 140 F. circulates through troughs in the floor. The temperature of the air in the caverns varies from 102 to 110 F. and the relative humidity from 87 to 93 per cent. Thus there are provided natural fever therapy rooms at nearly ideal temperatures and humidities.

During a treatment session of twenty minutes in these caves the patient's systemic temperature will rise 2 to 3.5 degrees F. Already these caves have appeared to be of some benefit, when employed in conjunction with effleurage, in treatment for filariasis. The caves have been also used in verifying the cure of malaria. The

Fig. 7.—Convalescent patients at archery practice at Ashford General Hospital.

peripheral capillary dilatation produced by the heat of the caves apparently serves to draw into the blood stream the malarial parasites which may be lurking in the spleen, liver or other organs. Thus latent malaria may be reactivated.

In conjunction with the therapeutic pool and thermal caves an excellent physical therapy department and therapeutic gymnasium have been constructed. Also there are plans for construction of an occupational therapy department, a complete wood working shop and a leather working and a weaving shop. These will be coordinated with physical therapy, therapeutic exercise and corrective occupational therapy.

A typical day for a convalescent patient will include the following program: 7 a. m., breakfast; 7:30 to 8:30 a. m., make bed and clean locker; 8:30 a. m.,

Fig. 8.—Fitzsimons General Hospital, Denver.

sick call; 9 a. m., calisthenics class; 10 a. m., swimming class; 11 a. m., treatment in department of physical medicine; 12 noon, mid-day meal; 1 to 3 p. m., light work detail; 3 to 5 p. m., organized sports assignment (sports commensurate with the patient's disability); 5 p. m., evening meal, and 6 p. m., liberty or recreational period. This program is elastic and can be modified to

fit individual needs. According to Lieutenant Drewyer this "regular program fosters habits of diligence and self respect and converts indolent and often discontented patients into happy men who soon begin to feel that they are becoming useful members of society." The program "has for its theme the development of a competitive spirit—the spirit to get well."¹⁹

One cannot help thinking that, with such splendid progress being shown in rehabilitation of the injured at army and navy hospitals, as typified by the Ashford exercise program, the Fitzsimons convalescent ward program and the Glenwood Springs general rehabilitation program, our American soldiers and sailors are going to make the same rapid progress as was shown by the Royal Air Force air gunner mentioned by Watson Jones. The Glenwood Springs project is particularly interesting and it may become, as Shepherd's Bush became in the last war, the model for other rehabilitation centers throughout the country. Similarly civilian hospitals are beginning to consider plans for the rehabilitation of injured industrial workers and civilians in other fields. For example, the Michael Reese Hospital in Chicago is contemplating the establishment of an elaborate convalescent center, which can serve the purpose mentioned. Dr. C. O. Molander²

Fig. 9.—United States Naval Convalescent Hospital, Glenwood Springs Colo.

has recently informed me about this project. It is obvious that civilian hospitals as well as military hospitals must augment their rehabilitation services greatly. It is also apparent that our American health resorts can be utilized to advantage for the rehabilitation of industrial and other civilian casualties.

FINAL COMMENT

American health resorts should play an extremely important role in rehabilitation of the disabled. As our war casualties, both military and civilian, increase it is encouraging to observe the important steps which are already being taken.

As with the related postwar educational program, if he is to cooperate, the medical rehabilitation plan must appeal to the man for whom it is provided.

It has been explained by a committee of the Association of Medical Colleges²¹ that "to be at once realistic and useful, any program must reckon with the probable

SATURDAY, JULY 29, 1944

COUNCIL ON PHYSICAL THERAPY BECOMES COUNCIL ON PHYSICAL MEDICINE

At the nineteenth annual meeting of the Council on Physical Therapy during December 1943 a motion was passed unanimously recommending to the Board of Trustees that the name be changed to the Council on Physical Medicine. At the recent annual session of the American Medical Association in Chicago the Board of Trustees recommended to the House of Delegates, and the House of Delegates acted favorably on this recommendation; as a result, the Council on Physical Therapy has now become the Council on Physical Medicine.

The designation "physical medicine" is a more inclusive term. Physical agents are used not only for therapy but also for diagnosis. Hospital departments of physical medicine, when they employ electric tests for reaction of degeneration or perform such tests as the cold pressor test, are employing physical agents not for therapy but for diagnosis.

The Council has for some time interested itself in certain phases of occupational therapy, which is a branch of the broad field of physical medicine. The Council was informed that the American Occupational Therapy Association was anxious to have the Council give more attention to occupational therapy. Discussions between representatives of the Council and the American Occupational Therapy Association indicated that the association would welcome the inclusion of occupational therapy under a Council on Physical Medicine.

Under the following definition for physical medicine, the entire field can be covered by a Council on Physical Medicine: Physical medicine includes the employment of the physical and other effective properties of light, heat, cold, water, electricity, massage, manipulation, exercise and mechanical devices for physical and occupational therapy in the diagnosis and treatment of disease. The Council believed that it would be wise to appoint a special subcommittee of five physicians interested in occupational therapy who could help to bring

this phase of therapy more fully under direct medical supervision.

Finally there is definite precedent for the use of the term "physical medicine," which has long been considered the most acceptable term by our British colleagues. The Conjoint Board of the Royal College of Physicians and the Royal College of Surgeons has just instituted a diploma in physical medicine.

With its new name the Council on Physical Medicine will continue to function as it has always functioned but will devote additional attention to problems of occupational therapy.

THE CELL THEORY IN PATHOLOGY

The manner in which the cell doctrine of Schleiden and Schwann was adapted to an interpretation of disease is interesting.¹ The idea that elementary cells, globules, vesicles or fibers may be united to form tissues was suggested in antiquity. The value of Schwann's theory depended on the morphologic and functional importance attributed to the nucleus. Unfortunately, coupled with it was the erroneous belief that cells originated within a formless blastema by a process of "crystallization"—actually a spontaneous generation.

The cell concept was introduced into the study of disease during the two decades beginning with the publication of Schwann's researches in 1838 and closing with Virchow's "Die Cellularpathologie," printed in 1858. At that time such histologic methods as are now employed were undeveloped. Tissues were placed in salt or sugar solutions, teased apart and examined in the fresh state. The only reagent in common use was acetic acid, which increased the prominence of the cell nuclei. The fixation, embedding, sectioning and staining techniques paramount in modern microscopic studies were unknown. An appreciation of the achievements of the early histopathologists and an interpretation of their errors are possible only if these deficiencies in their technical methods are recognized.

Schwann's blastema theory, i. e. a structureless solid or fluid in which cells subsequently appear much as crystals arise in a supersaturated solution, appealed to the pathologists. These investigators thought they had found such a blastema in recent thrombi and fibrinous exudates. They observed that cells similar to the cells described by Schwann in normal tissues appeared within these substances after several days. Pus, organizing thrombi and exudates were therefore interpreted in the light of Schwann's hypothesis. The possibility of an infiltration or proliferation of cells into the thrombus from the adjacent tissue did not occur to observers for many years. One of the earliest records of this view is found in a footnote by Busk and Huxley to their translation of Kölliker's "Manual

1. Schlumberger, H. G.: The Origins of the Cell Concept in Pathology. Archives of Pathology, to be published.

of Human Histology," 1853. They wrote "There cannot be said to be any evidence of the occurrence-of free cell development in animals, so long as in any case cited it is not shown that the first formed particles which make their appearance cannot have derived their origin from preexisting formed particles. . . . In pathological exudations, for instance, who shall determine that the first structural elements which appear, granules, free nuclei, exudation corpuscles, etc., are not directly derived either from the blood or from the tissue into which the exudation has taken place?"

Inflammation was considered to be the elaboration of an exudate derived from the blood. If the exudate was thin and watery it presumably lacked the necessary nutritive properties, and only a few granules or free nuclei could be engendered in it. The prognosis in such instances was grave. If, however, the exudate was thick, having the consistency of cream, it was thought to be rich in germinal substances and capable of producing many primitive cells. When the quantity of exudate was small the cells were thought to be directly converted into the tissue affected. The portion not used in cell production was thought to be resorbed or dried up. This served to explain healing by first intention, the small amount of fluid present in the wound being converted to epithelium at the surface and connective tissue in the deeper regions. If the quantity of exudate was somewhat greater and all of it converted into tissue cells, hypertrophy of the affected organ would result. When the amount of exudate was very large, many of the primary cells were not converted into tissue cells but washed away in the fluid medium as pus corpuscles. This concept of tissue formation seemed to lend support to the idea that a viscid yellow exudate was a "laudable pus."

A few investigators, notably William Addison, disagreed with this derivation of the pus cells, insisting that they were white blood corpuscles that had passed through the capillary walls into the tissues. As early as 1843, Addison recorded his microscopic observations on the web of a frog's foot which had previously been placed in warm water. He noted the peripheral position of the leukocytes in the dilated capillaries and their accumulation in the surrounding tissues. Although he did not witness the migration of the cells through the vessel wall, Addison insisted that it must be so and accounted for his failure on the ground that the "processes are too slow for us to follow from beginning to end all the actual stages."

Yet this work passed unnoticed. When it became clear that pus corpuscles like other cells must arise from preexisting cells, it was assumed that they were derived from epithelium or connective tissue. The discovery of tissue macrophages seemed to lend some support to this belief. In "Die Cellularpathologie"

Virchow expressed skepticism of the intravascular origin of pus cells.

The first extensive application of the cell doctrine in pathology was made by Johannes Mueller in his study of tumors. Schwann had taken up the microscopic examination of tissues on the suggestion of Mueller and carried out his investigation in the latter's laboratory. As early as 1835 Mueller described what he called the "fat cells" in a lipoma. His book on tumors appeared in 1838, shortly after the publication of Schwann's work. In it Mueller has words of high praise for his pupil and wholeheartedly accepts the blastema theory, believing that "the germinal cells of carcinoma do not arise from preexisting fibers but develop independently from a true morbid fluid between the tissue cells." Mueller noted that among other cells present in cancers were some spindle shaped ones which he called "tailed corpuscles." Other investigators at once interpreted these to be specific for all cancers; this in spite of the fact that Mueller had warned against the overenthusiastic use of the microscope as a diagnostic aid. In fact, he said that "microscopic and chemical analysis will therefore never become a means of medical diagnosis; it would be ridiculous to wish this or even consider it possible." Nevertheless, for decades thereafter pathologists sought the "tailed corpuscles" much as their predecessors had searched for the philosopher's stone.

During the decade 1845 to 1855 microscopists were much concerned with the structure of connective tissue, bone and cartilage. Virchow did important work in this field and first clearly expressed the view that connective tissue is cellular in character and that the lacunae in bone contain cells which are related to those of cartilage and connective tissue. The investigations of embryologists on the cleavage of the egg cell, and of plant and animal histologists on the growth of adult tissue, cast increasing doubt on the origin of cells within a blastema.

In 1852 Remak wrote that "the pathological tissues are no more formed in an extracellular cytoblastema than are normal structures, rather they are derivatives of normal tissues of the organism." Three years later, speaking specifically of tumors, but including all tissue growth, Virchow coined the aphorism *omnis cellula e cellula*. However, he replaced the blastema with the connective tissue, finding in the latter the source of all neoplastic growth. His insistence on the derivation of carcinoma from connective tissue led to much confusion and was not definitely refuted for many years. Nevertheless, with the publication of "Die Cellularpathologie" in 1858, Virchow presented physicians with a concept of disease which, though modified, is generally applicable today.

Current Comment

DEMEROL WITHIN PURVIEW OF NARCOTIC LAWS

With the approval, July 1, by the President of a law enacted by Congress just prior to recess, the synthetic drug designated as isonipocaine was brought within the purview of the federal narcotic laws. This drug is marketed in the United States under the trade name of "Demerol." All manufacturers, wholesalers, retailers and practitioners procuring, prescribing or dispensing Demerol, if not already registered, must effect registration in the appropriate class under the federal narcotic law. They must also submit to the collector of internal revenue having jurisdiction, on or before September 1, an inventory on appropriate forms of all Demerol on hand as of July 1, 1944. Physicians must submit the required inventory on form 713, which may be obtained from the collector's office. Hereafter manufacturers of Demerol must tax stamp each package before sale or removal. Wholesalers, retailers and practitioners who have in their possession unstamped packages of Demerol, quantities manufactured prior to July 1, must affix to each package their own label or paster bearing the legend "In stock, inventory July 1, 1944," followed by the name or initials of the owner. Packages without stamps or without identifying labels after a reasonable time will be subject to possible seizure and forfeiture. Essentially, the effect of this law is to subject the use of Demerol to the same restrictions imposed on the use of narcotic drugs, with the exception that no preparation containing Demerol in any quantity is exempt. The House of Delegates at its June session recorded its approval of this legislation. During 1944, state narcotic laws in six states were amended to bring isonipocaine within their coverage—Kentucky, Mississippi, New Jersey, New York, South Carolina and Virginia.

THE DEMOCRATIC PLATFORM

A careful reading of the platform recently adopted by the Democratic party discloses the following language that may relate directly or indirectly to a health program:

Beginning March 1933 the Democratic Administration . . . provided social security, including old age pensions, unemployment insurance, security for crippled and dependent children and the blind. . . .

We pledge the continuance and improvement of these programs. . . .

We offer these postwar programs:

A continuation of our policy of full benefits for ex-service men and women, with special consideration for the disabled. . . .

The enactment of such additional humanitarian, labor, social and farm legislation as time and experience may require, including the amendment or repeal of any law enacted in recent years which has failed to accomplish its purpose. . . .

We reassert our faith in competitive private enterprise free from control by monopolies, cartels or any arbitrary private or public authority.

CIVILIAN DEFENSE AT HARTFORD CIRCUS FIRE

On July 6 a disastrous fire at the Ringling Brothers Barnum and Bailey Circus in Hartford, Conn., resulted in the death of 150 persons and injuries to more than 200. Taking the lead in caring for the victims was the Hartford civilian defense organization, which provided blood plasma. The transfusion administration sets from the New York City Civilian Defense Emergency Medical Service also were instrumental in saving the lives of many of those seriously injured and burned. Dr. John J. Bourke, medical assistant to the director of the U. S. Office of Civilian Defense, reached Hartford by plane from LaGuardia Field with 150 transfusion administration sets and extra filters which had been requested by the Hartford Emergency Medical Service. More than 500 blood plasma sets were available at the time of the fire, and additional units of dry plasma were provided immediately. The emergency medical service set up in Hartford in connection with the Office of Civilian Defense served an invaluable purpose in this disaster. The continuance of this and similar organizations after the war will doubtless receive favorable action.

HEALTH PLATTERS IN PENNSYLVANIA AND ARIZONA

Radio "platter" (transcription) broadcasts furnished by the Bureau of Health Education are being broadcast over a number of radio stations in Pennsylvania under the auspices of the Committee on Public Relations of the Medical Society of the State of Pennsylvania. WFBG at Altoona will broadcast *Before the Doctor Comes*. WCED at Dubois has a set of *American Medicine Serves the World at War* and will start weekly broadcasts July 17. Dodging Contagious Diseases will go on WISR, Butler, for twelve weeks beginning Saturday, July 15. WBAX at Wilkesbarre is running *American Medicine Serves the World at War* on Monday, Wednesday and Friday and *Dodging Contagious Diseases and Before the Doctor Comes* on Tuesday and Thursday. Other broadcasts are scheduled tentatively. Altogether, twelve radio stations in Pennsylvania have requested broadcasts including three in Philadelphia and two in Pittsburgh; in cases like these, "first come, first served," says the state medical society. These radio transcriptions are available to any state medical society whose committee or officers will make the necessary arrangements for broadcasting within the state. They are available also to county medical societies and to health departments with the approval of county medical societies. Recent communications from the Arizona State Medical Association¹ indicate that there is a steady demand for copies of the scripts from listeners. One Arizona radio station says "we have had more audience response both by mail and phone than any other educational program in [their] history. Many have commented to their personal physicians about the programs—all have been along the lines that the listener was surprised and pleased at the helpful quality of the programs."

MEDICINE AND THE WAR

ARMY

INDUSTRIAL MEDICAL PROGRAM OF THE ARMY

The Army is very likely the largest single employer in the country today.¹ Not only does it operate its own arsenals, depots and industrial plants, but also the Surgeon General's Office is responsible for sanitation, hygiene and medical supervision over army owned contract operated installations which are located on military reservations. The chain of responsibility extends through the Surgeon General, who establishes policy and maintains advisory supervision, into the service commands, the army air forces, to the ports of embarkation under the control of the chief of transportation, and to the chief of ordnance.

In the Surgeon General's Office the Occupational Health Division functions in the Preventive Medicine Service. It establishes policy, gives technical advice, supervises the Army Industrial Hygiene Laboratory and maintains liaison with other governmental agencies concerned with industrial health and safety. The Army Industrial Hygiene Laboratory, located in the School of Public Health at Johns Hopkins University in Baltimore, surveys army industrial installations as to environmental hygiene and provides medical and engineering consultation to control occupational health hazards.

The plan of organization in each service command includes the appointment of a qualified industrial medical officer and a qualified sanitary corps officer as the industrial hygiene engineer, acting under the direction of the service command surgeon. These officers make inspections, recommend the installation of new or additional medical facilities, participate in industrial hygiene surveys and cooperate with other personnel in the service command in the control of absenteeism and the prevention of industrial accidents. Requests for assistance from the Office of the Surgeon General are transmitted by the commanding general of the service command.

The commanding general of the Army Air Forces makes use of the central agency set up in the Surgeon General's Office. He also is empowered to provide personnel for developing industrial medical services in army service forces commands and designates qualified medical officers and sanitary officers to conduct adequate industrial health programs. The chief of transportation acts in an identical capacity at the ports of embarkation.

In the installations themselves medical responsibility may reside in a medical officer, a contract surgeon or civilian physician as circumstances suggest. In any case the duties include physical examination (preplacement and periodic), emergency care, immunization, control of occupational health hazards, maintenance of proper reports and records, industrial hygiene consultation services, health programs, cooperation with safety programs and the necessary measures for a healthful work environment. In all of these services the responsible officer is assisted by the industrial hygiene engineer.

Special regulations apply to personnel. Civilian physicians qualify for assignment through civil service, or contract surgeons are employed to conduct the medical services at all army operated industrial plants. Such employment customarily follows after authorization by a service command and after clearance with the Procurement and Assignment Services. Funds are allotted by the service command. Registered graduate nurses not eligible for service in the Army Nurse Corps are generally employed in army operated plants. This rule can be modified only by special action of the commanding generals of the army service forces or army air forces. Supplies and equipment are available from the Surgeon General or appropriate medical department distribution depot.

1. Industrial Medical Program of United States Army, Circular 198, War Department, Washington, D. C., May 20, 1944.

COL. SANFORD W. FRENCH II RETIRES

Special orders were issued recently from the headquarters of the Fourth Service Command announcing that Col. Robert C. McDonald, commanding officer of the England General Hospital, Atlantic City, is replacing Col. Sanford W. French II as Fourth Service Command surgeon. Colonel French, who has been command surgeon for the past two and a half years, is on sick leave from the Lawson General Hospital. His retirement will end a military career of forty-two years' continuous service, eight years as chief petty officer in the Navy with service in Guam and the Philippine Islands and thirty-four years in the Army with service in Panama and at ten different posts within the United States.

In addition to heading the medical branch, Headquarters Fourth Service Command, Colonel French was the instigator of establishing eighty-nine allergy clinics in 1942 at general and station hospitals throughout the command. Another project which Colonel French was instrumental in establishing is the treatment of acute venereal diseases while patients are kept on a duty status. This project was pioneered in the Fourth Service Command in March 1942, but after a War Department report in 1943 it was made standard operating procedure for all service commands. The most recent program with which Colonel French has been affiliated is the reconditioning service for wounded men returning from overseas. Two years ago a small reconditioning service was set up in station hospitals, but it was not until recently that the need for a definite program was recognized by the Surgeon General's Office in Washington. The Daytona Beach Convalescent Hospital, under command of Col. Philip L. Cook, is the latest Fourth Service Command installation giving full time to this new reconditioning program. Following his retirement, Colonel and Mrs. French will live in San Antonio, Texas.

EIGHT DECORATED FOR TYPHUS CONTROL SERVICE

The War Department has announced the award of the Bronze Star Medal to an officer of the Sanitary Corps and seven enlisted men of the Medical Department who conquered a virulent form of typhus on Goodenough Island in the South Pacific. Their citation states that, "Though fully aware of the danger of this particularly virulent form of typhus and its high mortality rate, they voluntarily applied themselves to the task of eliminating the causes of it. Their zeal and thoroughness resulted in the rapid and complete control of the disease on this island." Their services were rendered during the periods from Dec. 27, 1943 to Feb. 7, 1944 and March 13 to 22, 1944. The awards were made to:

Capt. Charles Lose III, East Cranford, N. J.
Staff Sergeant John O. Beasley, Charleston, W. Va.
Sergeant William G. Osborn, Bronx, New York.
Technician (4th grade) Joseph H. Downing, Cranford, N. J.
Technician (4th grade) Joseph S. Burat, Swedesburg, Pa.
Corp. Stephen P. Findeis, Linden, N. J.
Technician (5th grade) Nicholas A. Barbarotto, Bronx, N. Y.
Technician (5th grade) William M. Stokes, West Collingswood, N. J.

ARMY HOSPITALS MERGE

The Fort Benjamin Harrison Station Hospital (Fort Benjamin Harrison, Indiana) will consolidate with the Billings General Hospital, it was announced recently, by Col. Henry E. Tisdale, commanding officer of the fort. Major S. T. Stenberg, post surgeon, will have charge of a dispensary to be established for personnel now being cared for in the station hospital. Dispensary cases requiring hospitalization will be transferred to Billings Hospital. Many buildings now utilized

by the station hospital will be transferred to the jurisdiction of Col. Harry L. Dale, commanding officer of Billings Hospital. All medical activities of the reception center, the post sanitary service, dental service and physical examination required for fort personnel will continue under the jurisdiction of Colonel Tisdale, who states that the consolidation of these hospitals is a step toward more economical and efficient operation.

AIR EVACUATION AIDS WOUNDED IN BURMA

Col. Don Flickinger, wing surgeon of the AAF Air Transport Command, India-China Wing, who recently returned to the United States for reassignment, told of the increasing number of sick and wounded being evacuated by air transport in the China-Burma-India theater of operations and disclosed that among them were hundreds of Chinese soldiers wounded in action against the Japanese in Burma. Hundreds of other casualties of the Allied ground forces fighting in Burma also are being evacuated by air, the total number of patients in March being 1,106 and in April 1,342. Six regular air evacuation "runs," one of them over the Hump, are made by the Air Transport Wing each week, the patients on each being cared for by flight surgeons and flight nurses.

Air evacuation medical personnel are facing the same hazards that the ATC pilots do on such runs. In one instance a flight nurse, a flight surgeon and an enlisted surgical technician were wounded when a Japanese bomber bombed and strafed their field just as they were taking off in a transport plane. Colonel Flickinger stated that the general health of the flying personnel making the dangerous trips over the Hump, taking in supplies to China, was good. Many factors, such as better sanitation, food, living conditions, emergency rescue, training and rotation of air crews back to the United States, have greatly improved the physical and mental status of the personnel. Colonel Flickinger said that the three principal reasons for the good standard of health maintained in the wing were the basic toughness of the American soldier, the vigilance of medical officers and the support and backing of the commanding general in all recommendations by the flight surgeon.

In August 1943 Colonel Flickinger parachuted with medical supplies to the aid of 20 survivors of a four engine transport plane which crashed in a wild region of Burma. The survivors included two U. S. government officials, a radio news commentator and Chinese army officers. Colonel Flickinger was awarded the Legion of Merit in 1942 for his experiments with devices to aid in sighting pilots forced down at sea. He also holds the Distinguished Flying Cross, Soldier's Medal, Air Medal and a Presidential unit citation.

ARMY TAKES OVER MASON GENERAL HOSPITAL

The Mason General Hospital, Brentwood, L. I., N. Y., was turned over formally to the Medical Corps on June 22 and was dedicated to the recovery of psychoneurotic casualties from both battle and training areas. Major Gen. Norman T. Kirk, Surgeon General of the Army, gave the dedicatory address. Built by the state of New York as a unit of Pilgrim State Hospital, which it adjoins, the Mason General Hospital can house 1,348 patients normally and 2,000 in an emergency. It has twenty-eight wards on seven floors in four modern fire-proof pavilions radiating from central kitchens and mess rooms on each floor. The Army also has established at the hospital its special school for training medical officers in psychoneurology. It already has 1,000 on such duty and will add seventy graduates of classes which go through the hospital every three months. These graduates go directly to the front. The faculty of the school is headed by Col. William C. Porter.

The hospital was named in honor of Brig. Gen. Charles F. Mason, who had a distinguished career in the Medical Corps and who died in 1922.

Col. Steve C. Odom is the commanding officer of the hospital.

MEDICAL ADMINISTRATIVE OFFICER QUOTAS RAISED

An increase in quotas for admissions to officer candidate courses leading to commissions in the Medical Administrative Corps of the Army was announced July 12. The new quotas permit acceptance of 2,000 men within the next eight weeks for seventeen week courses. The increase will permit more Medical Administrative Corps officers to free members of the Medical Corps for professional duties. Under the new plan the Officer Candidate School at Carlisle Barracks, Pennsylvania, was reopened on June 24. Three more classes of 500 men will be admitted to Camp Berkeley at two week intervals during the summer. Two classes of 250 men each will start, four weeks apart, at Carlisle Barracks in addition to the class now in training there.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Samuel B. Prevo

Lieut. Col. Samuel B. Prevo has been awarded the Soldier's Medal by Major Gen. C. L. Chennault for distinguishing himself by heroism in his capacity as surgeon of the East China Wing of the 14th U. S. Air Force. Dr. Prevo, who was formerly surgeon with the AVG's in China, was on duty last December as medical officer of the day when a heavy bombardment plane loaded with bombs crashed while taking off. Some of the bombs were delayed action type whose fuses had been damaged by the crackup, endangering the lives of all in the crash area. Dr. Prevo, nevertheless, aided in extinguishing the fire and then worked continuously for eight hours helping to extricate crew members from the wreckage and treating the injured. During this period he crawled into the plane several times to administer sedatives to men trapped in the plane. The citation accompanying the award read "By exposing himself to great personal danger in order to save the lives of others he demonstrated heroism in keeping with the finest traditions of the American military service." Dr. Prevo graduated from George Washington University School of Medicine, Washington, D. C., in 1937 and entered the service in February 1941.

Captain Henry H. Hancock

For crawling through minefields and enemy fire to rescue a wounded soldier during the Sicilian campaign, Capt. Henry H. Hancock was presented the Silver Star for gallantry in action. The citation accompanying the award read "During an attack on . . . Sicily, on . . . July 1943, a soldier from Company C, . . . Infantry, was wounded in the chest by machine gun fire and was bleeding profusely. In order for medical aid to be rendered to him, it was necessary for Captain Hancock to pass through enemy minefields and barbed wire, in view of enemy positions. Captain Hancock, with utter disregard for his own safety and with full knowledge of the existing dangers, worked his way forward through these obstacles and was successful in effecting the evacuation of the soldier. The speedy rendition of this medical aid and the unselfish, courageous action of Captain Hancock resulted in the saving of the wounded soldier's life. The gallant conduct of this officer was an inspiration to all who witnessed it and reflects great credit on him and the military service." Dr. Hancock graduated from the University of Virginia Department of Medicine, Charlottesville, in 1937 and entered the service Sept. 20, 1942.

Captain Emory C. Kinder

Capt. Emory C. Kinder of Kingstree, S. C., has been awarded the Soldier's Medal in England, where he is a flight surgeon with an Eighth AAF Flying Fortress group. Dr. Kinder was decorated for heroism in risking his life to save a wounded gunner who was pinned in a flying fortress by a live bomb which entered the tail of the plane. After the fortress landed with the bomb embedded in its tail Dr. Kinder entered the ship and freed the tail gunner, although the bomb was in danger of exploding any moment. Dr. Kinder graduated from the Medical College of the State of South Carolina, Charleston, in 1939 and entered the service June 13, 1942.

NAVY

NAVY AWARDS AND COMMENDATIONS -

Captain French Robert Moore

The Legion of Merit was recently awarded to Capt. French Robert Moore "for meritorious conduct in the performance of outstanding service prior to and during action against Japanese forces on Tarawa, Gilbert Islands, Nov. 20-28, 1943. He effectively coordinated the efforts of medical units with the infantry teams and by his superb professional skill and knowledge contributed to the combat efficiency of the division. The fine record of the performance of medical units on Tarawa was in a large part due to his outstanding leadership and courage in the face of the enemy. On November 20, under heavy enemy fire, he participated in the rescuing of a number of wounded from under the pier and from damaged and stranded landing boats. His valorous action in rescuing these wounded, rendering first aid treatment and subsequently transporting them to a troop ship under fire was responsible for the saving of their lives. His thorough and complete spirit of cooperation, coupled with his painstaking forethought in organization and indefatigable and tireless devotion to duty, were of invaluable assistance and in keeping with the highest traditions of the United States Naval Service." Dr. Moore graduated from the University of Oregon School of Medicine in 1926 and entered the service the same year. He is now on duty with the planning section of the Bureau of Medicine and Surgery of the Navy Department, Washington, D. C.

Captain Richard A. Kern

A Letter of Commendation was recently presented to Capt. Richard A. Kern, formerly of Wynnewood, Pa., "For meritorious and efficient performance of duty while serving as Medical Consultant on the Staff of the Commander South Pacific Area and South Pacific Force during the period from August 1943 to February 1944. Captain Kern, in discharging his duties, made his services available to every medical officer in the South Pacific Area, visiting every medical facility many times. He traveled throughout the forward and combat areas and worked with the medical officers in the front line of combat operations on Bougainville, British Solomon Islands. At all times his objective was to improve the treatment of the sick and wounded, and no undertaking was too great, nor any detail too small, to bring forth his best efforts toward that end. His tireless endeavors, professional ability and devotion to duty were in keeping with the highest traditions of the United States Naval Service." Dr. Kern graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1914 and entered the Navy Feb. 2, 1942.

Lieutenant Commander Milo A. Youel

The Navy and Marine Corps Medal was recently presented to Lieut. Comdr. Milo A. Youel "for heroic conduct in rescuing a comrade from drowning at Flamingo Beach, Culebra, on Jan. 25, 1941. Sighting a man struggling in the treacherous waters and apparently unable to help himself, Lieutenant Commander (then Lieutenant, Junior Grade) Youel gallantly risked his life in order to effect a rescue. Courageously diving into the heavy surf, he reached the side of the exhausted man and with extreme difficulty succeeded in bringing him to safety. His personal valor and daring initiative in the face of grave peril were in keeping with the highest traditions of the United States Naval Service." Dr. Youel graduated from the University of Minnesota Medical School, Minneapolis, in 1940 and entered the service July 24, 1940.

Lieutenant Francis Bruce Monroe

Lieut. Francis B. Monroe, formerly of Iron River, Mich., was recently awarded the Bronze Star Medal for service as set forth in the following citation: "For meritorious service as Medical Officer of a Boat Base during offensive operations in the Rendova-New Georgia Area, Solomon Islands, from June 30 to Aug. 5, 1943. Working tirelessly and with complete disregard for his own personal safety throughout the entire

campaign leading up to and including the capture of Munda, Lieutenant Monroe unhesitatingly proceeded to all forward areas where medical attention was needed and, skillfully administering first aid to the wounded under extremely hazardous conditions, was largely responsible for keeping the number of casualties to a minimum. Lieutenant Monroe's courageous conduct and unwavering devotion to duty in the face of grave peril were in keeping with the highest traditions of the United States Naval Service." Dr. Monroe graduated from the University of Chicago School of Medicine in 1940 and entered the service July 17, 1942.

Lieutenant Commander Henry Perkins Hopkins

The Bronze Star Medal was recently awarded to Lieut. Comdr. Henry P. Hopkins, formerly of Chatham, Mass. The citation read "For meritorious service as Regimental Surgeon attached to a Marine Regiment during operations in the Solomon Islands Area from Sept. 21, 1942 to July 29, 1943. Executing his duties under the most hazardous and trying battle conditions during three major engagements in the Matanikau River area on Guadalcanal, Solomon Islands, Lieutenant Commander Hopkins displayed exceptional zeal, courage and outstanding skill in ministering to the men under his professional care. Responsible for the health and welfare of his regiment during the rehabilitation stage, he successfully handled the many and varied problems of sanitation in the tropics and reduced to a minimum the hazards of infection and disease. His conduct throughout his vital combat period was in keeping with the highest traditions of the United States Naval Service." Dr. Hopkins graduated from McGill University Faculty of Medicine, Montreal, in 1932 and entered the service Sept. 9, 1941.

Commander Emmett L. Calhoun

The Silver Star Medal was recently awarded to Comdr. Emmett L. Calhoun. The citation accompanying the award read "Comdr. Emmett L. Calhoun (MC), U.S.N.R., Hoquiam, Wash.: Serving in the U. S. S. *Northampton* in the Solomons 26-27 Oct. 1942, he insisted on manning his station although weakened by a major emergency operation. He was seriously injured during an attack but next day, when 114 wounded survivors were brought aboard, he worked tirelessly for four days to relieve their suffering." Dr. Calhoun graduated from Northwestern University Medical School, Chicago, in 1925 and entered the service Feb. 28, 1942.

HOSPITAL CORPS OFFICERS

Seventy-two Hospital Corps officers completed a course in hospital administration at the National Naval Medical Center July 5. These officers are now being assigned to various naval hospitals throughout the United States. A new class of seventy-five Hospital Corps officers has been placed under orders to report to the U. S. Naval Hospital, National Naval Medical Center, Bethesda, Md., for a six months course in hospital administration. On completion of this course they will also be assigned to various medical department activities in the United States for duty.

A class of thirty-five Hospital Corps officers completed a special course in epidemiology at the National Naval Medical Center July 17. These officers will be assigned to various epidemiology units for duty.

NAVY PERSONAL

Lieut. Sara G. Krout, Dental Corps, U.S.N.R., is the first woman dentist to be appointed for service in the Navy. She was recently enrolled in the Women's Reserve, and her nomination for active duty is now pending. Dr. Krout is a graduate of the Schroeder College of Dentistry and Institute of Natural Sciences and the University of Riga (Latvia). She was naturalized in Chicago in 1921 and has been in private dental practice since 1928.

MISCELLANEOUS

FIRST BIRTHDAY OF U. S. CADET NURSE CORPS

The first birthday of the U. S. Cadet Nurse Corps was observed by a flag presentation ceremony on the steps of the U. S. Public Health Service building, July 1, in the nation's capital. The new white, silver and scarlet banner was presented by Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service, to Miss Lucile Petry, director of the Corps. It carries the emblem of the Maltese cross, distinguished insignia of the 100,000 Cadet Nurses now preparing, with the aid of full federal scholarships, for positions in essential civilian or military nursing. Frances P. Bolton, Congresswoman from Ohio and sponsor of the Bolton act creating the corps, was

Banner (at left) presented to United States Cadet Nurse Corps.

present at the ceremony. Other guests included Watson B. Miller, assistant administrator of the Federal Security Agency; Major Gen. Norman T. Kirk, Surgeon General, U. S. Army; Vice Admiral Ross T. McIntire, Surgeon General, U. S. Navy; Dr. L. R. Thompson, Dr. R. E. Dyer, Dr. Carl Miehle, Dr. W. T. Wright Jr., Mr. John K. Hoskins, Assistant Surgeon Generals of the U. S. Public Health Service, and Senior Surgeon Dr. V. M. Moore. Special events marking the first birthday celebration on the U. S. Cadet Nurse Corps also took place in New York, Chicago, Hollywood, Fort Worth and a few other cities.

Youngest of the women's uniformed organizations, the U. S. Cadet Nurse Corps has attracted thousands of members from all walks of life to serve in one of the finest professions open to women. These recruits, identified by their trim gray uniforms marked by silver Maltese crosses and red epaulets, are helping to make it possible for hospitals to release graduate nurses for more highly specialized civilian nursing positions and for duty with the armed forces at home and overseas.

PUBLIC HEALTH UNDER HITLER

According to *LaCroix* of March 2, 1944 (France) Professors Guillaïn and Mollaret have reported to the Medical Academy a number of serious poisoning cases among factory workers, which have paralyzed them in the upper limbs and eventually caused a general paralysis. An investigation disclosed that the poisoning was due to the utilization of industrial oils brought home by the workers to make potato chips. The academy recommended the public authorities to request all industrialists to warn the workers against the toxic qualities of lubricating oils.

According to *Universul* of March 6, 1944 (Rumania), at a meeting of the Council of Collaboration of the country of Cetates Alba (Ackermann) it was pointed out that all necessary preventive measures against typhus have been taken. No villagers are admitted into towns on market days except on producing a certificate to the effect that they have been properly deloused. In view of the insufficiency of the medical personnel needed for combating the current epidemics it was approved that two more physicians, refugees from Kirovograd, should be accepted into service.

Algemeen Handelsblad of March 10, 1944 (Netherlands) reports that, as in 1943, school children and infants will be supplied with vitamin C tablets this spring as from March 27. Pupils of all council and private schools, preparatory, ordinary and special elementary schools, extended elementary schools, secondary schools and schools preparing for universities and handicraft schools will be given the tablets. This applies to Dutch as well as to German children.

Berlingske-Tidende of April 28 (Denmark) reports that Denmark is now suffering from a serious shortage of physicians. "This shortage is caused by the fact that about 100 Danish physicians and especially assistant physicians are for the time being unable to practice in this country.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in *THE JOURNAL* July 22, page 855)

GEORGIA

Crawford W. Long Memorial Hospital, Atlanta. Capacity, 269; admissions, 9,737. Dr. L. C. Fischer, Administrator (interns, October 1).

ILLINOIS

Belmont Community Hospital, Chicago. Capacity, 125; admissions, 3,778. Miss Gertrude F. Scofield, Superintendent (interns).

MASSACHUSETTS

Worcester Hahnemann Hospital, Worcester. Capacity, 151; admissions, 3,372. Miss Erna M. Kuhn, R.N., Superintendent (interns).

MICHIGAN

St. Lawrence Hospital, Lansing. Capacity, 230; admissions, 6,897. Sister M. Assisium, Superintendent (interns).

MINNESOTA

Bethesda Hospital, St. Paul. Capacity, 180; admissions, 6,083. Rev. L. B. Benson, Superintendent (interns).

NEBRASKA

Lincoln General Hospital, Lincoln. Capacity, 213; admissions, 4,574. Mr. Robert B. Witham, Administrator (interns).

NEW YORK

Auburn City Hospital, Auburn. Capacity, 240; admissions, 6,844. Mr. Jerome F. Peck Jr., Superintendent (mixed residencies).

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

July 22, 1944.

Advantages of a Program for Athletics

One view on national physical fitness which is widely held here but which has not been given official expression is that, sooner or later sponsors and promoters of sports, both amateur and professional, will have to give primary interest to the health aspect. At present these sponsors and the participating athletes are largely the beneficiaries of any accruing financial, publicity or prestige advantages, and it is believed that the youth of the nation can be helped to participate considerably more from the standpoint of physical well-being.

A letter recently received from a navy ensign who is in the Pacific contained the statement "almost every invasion plan out here seems to be: After landing, remove dead bodies and commence laying out a baseball diamond." This, according to the informant, indicates the attitude of men on the fighting fronts toward sport, which, he added, is of course a point that needs no arguing. Most healthy young people like sports and take part in one or another of them. But it does emphasize that when our boys come back we are likely to have an even more sport minded nation. "The sports world itself must soon take up its share of this job of improving national physical fitness. Just as physical education officers and doctors throughout the United States are endeavoring to improve standards of health and physical fitness, so must every leader in sports. Physical fitness is an over all responsibility of the sports fraternity, and it is high time they assumed that responsibility."

The progressive stand taken by Russia in refusing to allow her supply of doctors to be drained away into fighting services was mentioned as an attitude toward physical fitness that might be emulated in this country. It was pointed out that the Russian nation makes physical culture an integral part of the national program of sports. A report by the chief of the physical culture department of the Russian All Union Council of Trade Unions and president of the National Association of Gymnasts reveals the emphasis that the Soviet gives to sports among industrial

and office workers. For instance, trade unions alone have 212 stadiums, 1,559 athletic fields, 420 skiing clubs, 238 water sports clubs, 552 gymnasiums, 20 athletic clubs, 29 alpine camps and 4 cycling tracks. Prior to the war the membership of the athletic societies included 170,000 trackmen, 166,200 volley ball players, 157,000 skiers, 135,400 gymnasts, 237,600 hunters, 114,000 chess players, 103,000 soccer players and over 300,000 alpinists. Most of these are now fighting against the Nazis, many having been decorated for distinction in action.

These figures might not appear significant in comparison with numbers of athletes in one segment of the American population, but they were mentioned as indicating how health consciousness can be developed in a program of organized sports.

Definite progress is believed here to come from the plans for National Physical Fitness Year formulated jointly by the American Medical Association and the National Council on Physical Fitness. It is acknowledged that much can be done to remedy the drastic national situation revealed in draft rejection figures by emphasizing physical conditioning during the twelve months commencing September 1. But it is believed that this emphasis should continue indefinitely. The platform recommended for approval by the National Council on Physical Fitness at the July 27 and 28 meeting in Washington is regarded as a positive step in this direction. While this platform rightfully stresses the fact that attainment of physical fitness is primarily an individual responsibility, the problem would be made much easier if all the dramatization and inspiration that organized sport can promote were to back up the individual. Sports world leadership would advantageously complement the leadership expected of education, medicine, dentistry, public health, industry, labor "and other organized groups."

With sports and recreations now available for almost every one, it would give an added incentive if the public at large would learn that our national pastimes were being promoted for other purposes besides enriching or glamorizing a few lucky individuals. And sports, so efficiently organized professionally and in the amateur field, have the facilities already available into which national physical fitness could be incorporated as an integral function.

WOMAN'S AUXILIARY

Minnesota

At the Minnesota state convention held in Rochester, April 13-14, the auxiliary's projects for the year were given as cadet nurse requirement, collection of medical and surgical relief supplies, making of dressings for a cancer hospital, the dissemination of cancer control information, the placing of *Hygeia* in schools and clubs, and a thorough study of the Wagner-Murray-Dingell bill.

Mississippi

The Mississippi auxiliary held its annual state convention May 9-10 with Mrs. Eben J. Carey, national president, the guest of honor and speaker.

New York

The Nassau County auxiliary of New York has 159 members, 49 of whom are wives of men in service. These members have done 6,000 hours of war work, given \$100 to the Physician's Home Fund, provided speakers to talk on legislation and donated *Hygeia* to eleven schools and seventeen libraries.

Oregon

The Woman's Auxiliary to the Oregon State Medical Society has a room in the University of Oregon Medical School Library where are displayed on shelves a collection of historical medical books. Many collections have been added recently, among

them a display of Japanese medical equipment found in shell holes on one of the Gilbert Islands. Others are old medical books and instruments belonging to pioneer Oregon physicians.

Pennsylvania

The Woman's auxiliary to the state of Pennsylvania began its Medical Benevolence Fund in 1927 with the sum of \$100. Since then the contributions have reached \$56,667. Mrs. Walter Orthner, the president, writes "Words can never express the great good this money has done."

Tennessee

Mrs. W. A. Ruch, president of the Woman's Auxiliary to the Tennessee Medical Association, has visited every auxiliary in her state. She is also a worker in the Red Cross, as chairman of nutrition in Memphis and Shelby counties, and chairman of the Cutting of Surgical Dressings.

Virginia

The Woman's Auxiliary to the Nothhampton-Accomack Medical Society of Virginia held its quarterly meeting at the home of Mrs. Joseph E. Gladstone at Exmore recently. Rev. W. K. Haddock spoke on "The Five Tensions in the World Today." The next meeting will be an all day picnic at the cabin of Mrs. W. L. Cosby at "Silver Beach" on July 11.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Paul Bucy to Give Gorgas Lecture.—Dr. Paul C. Bucy, professor of neurology and neurologic surgery, University of Illinois College of Medicine, Chicago, will deliver the annual lecture of the Gorgas Medical Society at the University of Alabama School of Medicine, University, August 4. His subject will be "Movement and the Cerebral Cortex."

CONNECTICUT

Alvarenga Prize Awarded to Gervase Connor.—The College of Physicians of Philadelphia on July 14 awarded its Alvarenga Prize to Dr. Gervase J. Connor, instructor in surgery, Yale University School of Medicine, New Haven, for his work on "Anterior Cerebellar Function, an Analytical Study in Functional Localization in the Cerebellum in Dog and Monkey." The Alvarenga Prize was established by the will of Pedro Francisco da Costa Alvarenga, Lisbon, Portugal, an associate fellow of the college of physicians, "to be awarded annually by the College of Physicians on each anniversary of the death of the testator, July 14, 1883, to the author of the best memorial on any branch of medicine which may be deemed worthy of the prize." The college usually makes this award for distinctive published work and invites the recipient to deliver an Alvarenga Lecture before the college. In the recent instance the college awarded the prize for an "exceptionally important manuscript submitted in competition."

DISTRICT OF COLUMBIA

Medical Mission Goes to Study Aleutians.—A three man medical mission was to leave early in July for a visit in the Pribilof Islands in the Bering Sea to help local medical personnel to study and examine 400 Aleut natives who recently were repatriated after a two year stay in southeastern Alaska. Members of the mission include Dr. William A. Morgan, Dr. Roy Lyman Sexton and R. K. Thompson, D.D.S., all from Washington.

Latin American Visitors.—Marcelo Martínez Repetto, hematologist of Mérida, Mexico, has arrived in Washington at the invitation of the Department of State for three months' study and observation. —Dr. Ernesto Cofiño, professor of pediatrics on the Faculty of Medicine at Guatemala City, is also a guest of the state department for official study of child welfare programs in this country. —Dr. Amadeo Grosso Rossi, director of the Durazno Hospital, Durazno, Uruguay, and public health supervisor for the Durazno Department, which has some forty-five hospitals in all, is also a guest of the state department and is visiting the United States to study surgical practice and teaching technics.

ILLINOIS

Personal.—Dr. William R. Roberts, Cissna Park, and Dr. James McIlwain, Okawville, were recently made members of the fifty year club of the Illinois State Medical Society.

Special Society Elections.—Dr. Paul P. Youngberg, Moline, was elected president of the Iowa-Illinois Central District Medical Association at its recent annual meeting. Other officers include Dr. Glen W. Doolen, Davenport, Iowa, vice president, and Drs. James Dunn, Davenport, and Florens E. Bollaert, East Moline, who were reelected secretary and treasurer respectively. —Dr. David Slight was chosen president of the Illinois Psychiatric Society at its annual meeting in May. Dr. Joseph A. Luhan is the vice president and Dr. Frances Hannett the secretary-treasurer. All are of Chicago.

Chicago

Rush Alumni Election.—Dr. Hillier L. Baker was elected president of the alumni of Rush Medical College at a luncheon recently. Drs. William S. Horn, Fort Worth, Texas, Willson B. Moody, Omaha, and Franklin R. Nuzum, Santa Barbara, Calif., were chosen vice presidents. Dr. John M. Dorsey was reelected secretary-treasurer.

Male Volunteer Aids at Presbyterian.—A corps of male voluntary aids has been working at Presbyterian Hospital. After fourteen lectures and demonstrations in technics of taking temperatures, changing beds and other duties, the men started to work on June 26. In general the men volunteers rotate on a 6 to 10 p. m. shift, three or four of them working at a time.

Theodore Wachowski Temporarily in Charge of Radiology Department.—Dr. Theodore J. Wachowski, assistant professor of radiology and assistant director and chief of x-ray therapy in the Research and Educational Hospitals, University of Illinois, outpatient tumor clinic, on a temporary basis has been appointed in charge of the department of radiology, University of Illinois College of Medicine, pending the selection of a permanent successor to the late Dr. Adolph Hartung.

Dr. Kretschmer Receives Honorary Degree.—Dr. Herman L. Kretschmer, President of the American Medical Association, on June 6 received the honorary degree of doctor of science from Northwestern University. Dr. Kretschmer graduated at Northwestern University Medical School in 1904. According to the citation accompanying the degree, Dr. Kretschmer is a loyal alumnus whose contributions to science, teaching and organized medicine have brought great credit to his alma mater.

Health Talks for the Public.—Dr. Josiah J. Moore, president of the Chicago Medical Society and treasurer of the American Medical Association, gave the first lecture, July 26, in a series of popular health talks for the public sponsored by the Chicago Medical Society and given at the Museum of Science and Industry. Dr. Moore's subject was "Facts About Cancer." Other speakers will be:

Dr. Samuel M. Feinberg, August 2, Allergy, Facts and Fiction.
Dr. James H. Hutton, August 9, Your Glands and What They Do To and For You.
Dr. Edward E. Piszczek, August 16, Present Day Knowledge of Infantile Paralysis.
Dr. Andrew C. Ivy, August 23, Aviation Medicine.
Dr. Austin E. Smith, August 30, Modern Miracles in Drug Warfare.

Physicians Cited by University of Chicago.—On June 10 three physicians were included among a group cited by the University of Chicago, June 10, as "useful citizens": Drs. Margaret Bell, Ann Arbor, Mich., school of medicine class of 1921; Harry J. Corper, Denver, school of medicine class of 1911 and Oliver Perry Kimball, Cleveland, who served his first medical year at the university in 1913-1914. Dr. Kimball for years sponsored and collected funds from Cleveland alumni to underwrite a local scholarship at the university. Dr. Bell is chairman of the physical education department for women and physician in the student health service at the University of Michigan. Dr. Corper is assistant professor of medicine at the University of Colorado School of Medicine, Denver. The citations are awarded by the university for unselfish and effective service to the community.

Seminar on Industrial Medicine and Surgery.—The American Mutual Liability Insurance Company sponsored a war seminar on industrial medicine and surgery at the Stevens Hotel, Chicago, July 12-13. A report on the end results of ninety-two operations for intervertebral disks was presented by Drs. Henry C. Marble, Boston; Eric Oldberg, Paul B. Magnuson and William A. Bishop, Boston. The treatment of burns and lessons learned from the Coconut Grove Disaster was presented by Dr. Charles C. Lund, Francis H. L. Taylor, Ph.D., and Dr. Stanley M. Levenson, Boston. Other speakers were:

Dr. Walter S. Priest, Penicillin Therapy.
Dr. Hollis E. Potter, The Wedge Shaped Vertebra.
Dr. Oscar A. Sander, Milwaukee, Health Hazards of Electric Welding.
Dr. Paul G. Dick, X-Ray Aspects.
Dr. Dallas B. Phenister, Shock and Blood and Plasma Therapy.

The doctor's part in the job placement of disabled veterans was discussed by Dr. Bishop, Col. Robert H. Kennedy, M. C., Dr. Lewis J. Pollock and Mr. Arthur H. Johnson, Boston.

KANSAS

State Medical Election.—Dr. William P. Callahan, Wichita, was chosen president-elect of the Kansas Medical Society at its recent annual session and Dr. Marion Truchheart, Sterling, was installed as president. Dr. Franklin R. Croson, Clay Center, is the secretary.

LOUISIANA

Robert Strong Resigns at Tulane.—Col. Robert A. Strong, M. C., has resigned as professor and head of the department of pediatrics, Tulane University of Louisiana School of Medicine, New Orleans. According to the *Bulletin* of the Orleans Parish Medical Society Dr. Ralph V. Platau, who

has been serving as acting head of the department since Colonel Strong went into service, has been named to the position. Dr. Platon graduated at the University of Minnesota Medical School, Minneapolis, in 1936 and served there as clinical assistant in pediatrics until he joined Tulane.

Ochsner Foundation Offers Fellowships.—The Alton Ochsner Medical Foundation, 3503 Prytania Street, New Orleans, announces the availability of a number of fellowships in various branches of surgery and medicine. Appointments will be made for a period of one year subject to renewal for a total of three years. The fellows will be encouraged to register in the Graduate School of Tulane University of Louisiana, where, if accepted, they can work toward an advanced degree. The Ochsner Foundation, of which Dr. Dean H. Echols, New Orleans, is medical director, was created in January. It is a nonprofit organization, chartered under the laws of the state of Louisiana for scientific, educational, charitable and literary purposes. Directors of the foundation are:

Mr. Theodore Brent, president of the Mississippi Shipping Company.
Dr. Edgar Burns, professor of clinical urology, Tulane University of Louisiana School of Medicine, New Orleans.

Dr. Guy A. Caldwell, professor of orthopedics at Tulane.
Dr. Francis E. Le Jeune, professor and head of the department of otolaryngology of the department of otolaryngology at Tulane.

Mr. J. Blanc Monroe, attorney.
Dr. Edward William Alton Ochsner, William Henderson professor of surgery and head of the department of surgery at Tulane.
Dr. Curtis H. Tyrone, New Orleans.

An announcement stated that, although a number of the trustees are on the faculty of the Tulane school of medicine, the Ochsner Foundation has no official connection with the school.

MICHIGAN

George Cummings Named Director of Laboratories.—Dr. George D. Cummings, associate director, bureau of laboratories, Michigan State Department of Health, Lansing, has been appointed director of the department's bureau of laboratories. He succeeds the late Clifford C. Young, D.P.H., Lansing, who had held the position since 1918.

Dr. Humphreys Appointed Director of Mental Hygiene.—The state hospital commission has named Dr. Edward J. Humphreys, Coldwater, as director of mental hygiene to succeed Dr. Frank F. Tallman, Lansing, resigned. Dr. Tallman has accepted a similar position in the Ohio State Department of Health (*THE JOURNAL*, June 24, p. 589). Four child guidance clinics, established by the Michigan legislature, will begin functioning in September in Wayne County, Pontiac, Grand Rapids and Ypsilanti.

NEW YORK

Typhoid Carriers.—A total of 438 typhoid carriers, exclusive of those in state institutions, were under supervision in upstate New York at the close of 1943. Twenty-eight new carriers were added to, and 27 were removed from, the register during the year, according to *Health News*. Sixteen were discovered as a result of epidemiologic investigation of sporadic cases of typhoid, 7 by means of release cultures, 2 on the basis of information furnished by the New York City Department of Health and 1 was discovered accidentally at the time of surgical drainage of the gallbladder. Two previously discovered carriers were added to the register; these carriers had been residing temporarily out of the state. Of the 27 carriers whose names were removed from the register, 17 died, 8 carriers were removed because of change of residence to a community outside the jurisdiction of the department and 2 were removed from the active list because of commitment to state institutions.

New York City

Graduate Course in Clinical Medicine.—Columbia University College of Physicians and Surgeons has announced a series of part time courses in clinical medicine at the Mount Sinai Hospital, beginning September 25. A full time course in the recent advances in gynecology is planned for November 13-18. Additional information may be obtained from the Secretary for Medical Instruction, the Mount Sinai Hospital, Fifth Avenue at 100th Street, New York City 29.

Richard Freyberg Joins Hospital for Special Surgery.—Dr. Richard H. Freyberg, assistant professor of internal medicine and in charge of Rackham Arthritis Research at the University of Michigan School of Medicine, Ann Arbor, has been appointed chief of the department of medicine and pediatrics at the Hospital for Special Surgery, effective September 1. Dr. Freyberg will succeed Dr. Carlisle S. Boyd, who has been appointed to the board of consultants of the hospital. The Hospital for Special Surgery is maintained by the New York Society for the Relief of the Ruptured and Crippled.

Isolation Period Changed for Meningococcic Meningitis and Poliomyelitis.—The New York City Board of Health on July 11 amended section 89 of the sanitary code relating to isolation of persons affected with meningococcic meningitis and poliomyelitis. The isolation period for both these diseases was formerly fourteen days. In the future it will be limited until the temperature has reached normal. In an announcement, the board stated that the treatment of meningococcic meningitis with the sulfonamide drugs and penicillin has definitely shortened the time of recovery. In the case of poliomyelitis public health authorities now consider that the length of the isolation period may be safely limited to the period when the temperature is above normal. The board also deleted the requirements for the exclusion of contacts to these diseases from school or work.

NORTH DAKOTA

Dr. Wicks Ends Twenty-Five Years in Academy of Ophthalmology.—Dr. Frederick L. Wicks, Valley City, founder and first secretary of the North Dakota Academy of Ophthalmology and Otolaryngology, has resigned as secretary after serving twenty-five years in the position.

State Medical Election.—Dr. James F. Hanna, Fargo, was chosen president-elect of the North Dakota State Medical Association at its recent annual meeting and Dr. Frederick L. Wicks, Valley City, was installed as president. Dr. Leonard W. Larson, Bismarck, is the secretary. The next annual session will be held at Minot.

New Public Health Officers.—Francis C. Lawler, Sc.D., professor of bacteriology and immunology, University of North Dakota School of Medicine, Grand Forks, was chosen president of the North Dakota Public Health Association at a recent meeting in Fargo. Other officers include Anthony L. Bavone, Minot, vice president, Robert O. Baird, Bismarck, treasurer, and Mrs. Laura K. McCrory, Bismarck, secretary.

Dr. George Campana Appointed State Health Officer.—Dr. George F. Campana has been appointed health officer of North Dakota, effective July 1. He succeeds Dr. Frank J. Hill, who resigned to become city health officer of Minneapolis. Dr. Campana has served as director of the division of preventable diseases of the North Dakota State Department of Public Health since June 1943, when he came from New Rochelle, N. Y., where he had been acting city health officer. Dr. Campana graduated at the New York Medical College Flower and Fifth Avenue Hospitals in 1925. He served as assistant district state health officer with the New York State Department of Health in 1941-1942.

OHIO

New Venereal Disease Control Officer.—Dr. Ralph J. Doran, U. S. Public Health Service, has been assigned to the Dayton division of health as venereal disease control officer. The Dayton quarantine hospital was recently designated by the state health commissioner, Dr. Roll H. Markwith, Columbus, as a center to provide intensive therapy hospitalization for patients with communicable venereal disease.

Dr. Follansbee Honored.—Dr. George E. Follansbee, Cleveland, for many years chairman of the Judicial Council of the American Medical Association, has been awarded the distinguished service award of the Academy of Medicine of Cleveland. The citation accompanying the award enumerated the many years of service of Dr. Follansbee to the academy and acknowledged that he had done as much as any living physician to bring the academy of medicine to its present position of importance and influence.

Personal.—Dr. Leon Goldman, assistant professor of dermatology, University of Cincinnati College of Medicine, has been granted a fellowship by the Association of American Medical Colleges to study during July and August in Costa Rica, Guatemala and Mexico.—Dr. William E. Maine is now commissioner of health of Youngstown.—Dr. Ralph W. Holmes, Chillicothe, has been appointed a member of the silicosis board of referees by the state industrial commission, succeeding the late Dr. William M. Doughty, Cincinnati. Other members of the board are Drs. Raymond C. McKay, Cleveland, and Joseph A. Muenzer, Toledo.

RHODE ISLAND

Hospital News.—Butler Hospital, Providence, the oldest in the state, on May 10 celebrated its 100th anniversary. Among the speakers on the program were Drs. Edward A. Strecker, Philadelphia, on "The Contribution of Psychiatry to Demo-

cratic Morale"; Gregory Zilboorg, New York, "Psychiatric Problems in the Wake of the War"; Karl A. Menninger, Topeka, Kan., "The War Against Fear and Hate," and Alan Gregg, New York, "The Place of the Endowed Hospital in the Future."—The estate of Frederick S. Peck, former state finance commissioner, and his wife was recently donated to the Homeopathic Hospital, Providence, for use as a convalescent home or children's hospital. Mr. Peck was president of the hospital board of trustees for sixteen years.

TEXAS

Narcotic Violations.—Dr. John Lawrence Kirby, Muleshoe, pleaded guilty in the U. S. District Court at Lubbock, June 5, to a violation of the federal narcotic law and was sentenced to a term of eighteen months in the U. S. Public Health Service Hospital at Lexington, Ky. Dr. Irby W. Fires, Seagraves, following a similar plea, was placed on probation for a period of one day. This information was received from the U. S. Bureau of Narcotics.

Appointments to Southwestern Medical College.—New appointments to the faculty of the Southwestern Medical College of the Southwestern Medical Foundation, Dallas, include those of Dr. William F. Guerriero, recently of the Louisiana State University School of Medicine, New Orleans, to associate professor of obstetrics and gynecology, and Miss Ann Rucker as registrar of the medical college.

Changes in Health Officers.—Dr. Ernest W. Prothro has been named as the acting officer of the Laredo-Webb County Health Unit, Austin, succeeding Dr. Arthur E. Ballard, who resigned to take a similar position at Belton.—Dr. Will M. Miller has been named director of the Corsicana-Navarro County Health Department, succeeding Dr. Finnis E. Sadler, resigned.—David F. Bradley, A. Surg., U. S. Public Health Service Reserve, has been placed in charge of the Wichita County Health Unit.

Personal.—Dr. Paul Brindley, professor of pathology, University of Texas School of Medicine, Galveston, recently returned from a hospital tour in Costa Rica, Guatemala, Honduras and Mexico City, where he had been making special studies in tropical medicine under the auspices of the John and Mary R. Markle Foundation.—Dr. Paul M. Rattan, Dallas, has been elected medical director of the Great National Life Insurance Company to succeed the late Dr. Dan R. Murchison, Dallas.—Dr. and Mrs. Marvin C. Overton Sr., Lubbock, recently contributed \$20,000 toward the construction of a Methodist Student Center in Lubbock, it is reported.

UTAH

State Medical Meeting in Salt Lake.—The Utah State Medical Association will hold its annual meeting in Salt Lake City, August 25-26, under the presidency of Dr. James P. Kirby, Salt Lake City. Among the speakers on the program will be:

- Dr. Vincent L. Rees, Salt Lake City, Postoperative Pulmonary Complications
- Dr. Alfred C. Callister, Salt Lake City, Use of Tube Grafts in Deep Contracture Scars Resulting from Burns.
- Dr. Maxwell M. Wintrobe, Salt Lake City, Current Views on the Diagnosis and Treatment of Nutritional Deficiency.
- Dr. Clarence O. Sappington, Chicago, Meaning of Industrial Medicine, Hygiene and Health, Medical Aspects of Industrial Practice.
- Dr. Leroy U. Gardner, Saranac Lake, N. Y., Silicosis; Tuberculosis in Industry.
- Dr. Edward William Alton Ochsner, New Orleans, Neurovascular Lesions
- Brig Gen John M. Willis, M. C., Medical Administration and Hospitalization in a Service Command
- Col William J. Kenuard, M. C., Experiences in the AAF Convalescent Program.
- Lieut Col Ambrose H. Storck, M. C., Abdominal Wounds—Management and Results in the Present War.
- Major John H. Clark, M. C., Medical Service on Gaudalcanal.
- Capt. LeRoy J. Kleinsasser, M. C., Surgical Treatment of Peripheral Vascular Disease.
- Capt. Floyd J. Putney, M. C., Treatment of Lateral Sinus Thrombosis with Utilization of Penicillin
- Capt. Radford C. Tanzer, M. C., Plastic Surgery of War Injuries.
- Lieut Col. Leander W. Riba, M. C., Treatment of Certain Types of Urinary Obstruction.
- Major Max T. C. Schmitker, M. C., Osteomyelitis of the Skull—Its Treatment with Penicillin and Repair of Defects with Tantalum Plate.
- Major Clyde S. Roof, M. C., Indications for the Use of Various Intravenous Solutions
- Major Hazen B. Daines, M. C., Otitis Media.
- Lieut. Col. Lauren H. Smith, M. C., Treatment in War Psychiatry.
- Lieut. Col. John J. Loutzenheiser, M. C., Program of Occupational Rehabilitation in Relation to Medicine
- Major James R. Patrick, A. G. D., Use of Abilities and Skills in Morale and Rehabilitation.

WEST VIRGINIA

Hospitals Waive Fees for Tornado Victims.—The two Clarksburg hospitals, St. Mary's and Union Protestant, have waived all fees for rooms and services in connection with the treatment of victims of the tornado which devastated part of the city of Shinnston, June 23, taking a toll of seventy lives and sending more than 200 persons to the hospitals for treatment. Previously, on July 7, the Harrison County Medical Society voted unanimously to waive all fees for medical service (THE JOURNAL, July 22, p. 861). The decision of the authorities of the two hospitals means not only that there will be no charge for rooms but that fees for all usual services, including x-ray and laboratory, will also be waived.

Changes in Venereal Disease Bureau.—Dr. John C. Hume, U. S. Public Health Service, who has been serving as venereal disease control officer at Wilmington, N. C., has been detailed as acting director of the bureau of venereal diseases of the West Virginia Department of Health to succeed Dr. Leon A. S. Saler, U. S. Public Health Service, who has been transferred to Baltimore. Dr. Saler has been acting director of the bureau for the past three years. Dr. Wilfred H. Zwahlen, Logan, venereal disease control officer for the southwestern West Virginia District, has been transferred to the Kanawha Valley Medical Center at Charleston, replacing Dr. Lawrence M. Zell, who has been assigned to Wilmington, Del.

WYOMING

State Medical Election.—Dr. William Andrew Bunten, Cheyenne, was chosen president-elect of the Wyoming State Medical Society at its recent annual meeting and Dr. Thomas J. Riach, Casper, was installed as president. Dr. Marshall C. Keith, Cheyenne, is the secretary. The next annual session will be held at Casper.

GENERAL

Board of Technologists Announces Examinations.—The board of registry of the American Society of Clinical Pathologists announces that the fall examination for registration will be given on October 27. Applications must be submitted by September 1. Blanks may be obtained from Mrs. Ruth Drummond, Registry of Medical Technologists, Ball Memorial Hospital, Muncie, Ind.

Changes in Rockefeller Foundation.—Dr. Hugh H. Smith, a staff member of the International Health Division of the Rockefeller Foundation since 1930, has been appointed regional director of the United States, Canada and Mexico. Dr. Smith succeeds Dr. John A. Ferrell, who recently became medical director of the John and Mary R. Markle Foundation (THE JOURNAL, July 8, p. 730). Dr. Smith on September 1 will also become assistant director of the International Health Division. Dr. George K. Strode, who has been acting director of the International Health Division since June 1, will become director on September 1. At the same time Dr. Andrew J. Warren, assistant director in the division, will become associate director.

National Vitamin Foundation.—The organization of a National Vitamin Foundation was approved at a meeting of fifty representatives of all sections of the vitamin industry in New York, May 23. Its objectives would be to award grants for research in the vitamins or related fields, the dissemination of information to the vitamin trade, medical profession and public with respect to the quality, purpose and uses of vitamins, adoption of terminology and standards of publicity practices in connection with the sale of vitamins, and to confer and consult with medical societies, medical schools, health organizations, public health agencies and governmental agencies with respect to vitamins and the vitamin industry. The foundation would be administered by a board of trustees. Details of the organization are to be formulated by a committee of which Basil O'Connor, New York, president of the National Foundation for Infantile Paralysis, has been named chairman.

Special Society Elections.—Dr. Alfred I. Folsom, Dallas, was chosen president-elect of the American Urological Association at its meeting, June 22, and Dr. Clyde L. Denning, New Haven, Conn., was installed as president. Dr. Thomas D. Moore, Memphis, Tenn., is secretary and Dr. Herbert H. Howard, Boston, treasurer.—At the meeting of the medical section of the American Life Convention on June 23 in Chicago Dr. John M. Livingston, medical director of the Mutual Life Assurance Company of Canada, Waterloo, Ont., was elected chairman, succeeding Dr. Thomas H. Dickson, medical director of the Minnesota Mutual Life Insurance Company.

St. Paul. Dr. Benjamin F. Byrd, Nashville, medical director, National Life and Accident Insurance Company, was elected secretary.—Dr. Max Thorek, Chicago, was named president of the American Physicians' Art Association and Drs. George Harvey Agnew, Toronto, and William Rowland Davies, Scranton, Pa., vice presidents. Dr. Francis H. Redewill, San Francisco, was reelected secretary-treasurer.

Kellogg Foundation Creates Advisory Committees.—The W. K. Kellogg Foundation, Battle Creek, Mich., has recently appointed advisory committees in a number of fields that comprise its major interests to evaluate the present programs and activities, review the major financial requests presented to the foundation and develop worth while activities in their respective fields that are consistent with the policies and philosophy of the foundation. Committees have been named in the fields of public health, hospitals, nursing, education and libraries. Plans are being made to name one in medicine and one in public health engineering. Among the advisory committees already named are the following:

Public Health Advisory Committee

Dr. Wilson G. Smillie, New York.
Dr. Gregoire F. Amyot, Victoria, B. C., Canada.
Dr. Henry F. Helmholz, Rochester, Minn.
Dr. Hugh R. Leavell, Louisville, Ky.

Hospital Advisory Committee

Mr. James A. Hamilton, New Haven, Conn.
Dr. Robin C. Buerki, Philadelphia.
Lieut. Col. Basil C. MacLean, M. C.
Mr. John R. Mannix, Chicago.

Nursing Advisory Committee

Mrs. Leath Blaisdell Bryan, New York.
Miss Minnie E. Pohe, Washington.
Miss Ruth B. Freeman, Minneapolis.
Miss Lucile Petry, Washington.

The committees will meet two to four times a year in Battle Creek and will be available to the officers of the foundation on a consultation basis throughout the year.

Changes in Obstetric Board Requirements.—At the annual meeting of the American Board of Obstetrics and Gynecology in Pittsburgh June 7-13, approval was given to the waiver temporarily of the requirement of membership in the American Medical Association for men in the Army or Navy, especially for those who proceeded directly or almost so from hospital services into the army or navy service, with the condition that a statement is given of intention to join promptly when returned to civilian practice. The board also accepted a period of nine months as an academic year in satisfying its requirements for certain years of training. This is only for the duration, and even men who are not eligible for military service but who are nevertheless in hospitals where the accelerated program is in effect have been allowed to submit to the board this short-time period of training in lieu of our previous requirements. Beginning with the next written examination, which is scheduled to be held the first Saturday afternoon in February 1945, the board will limit the written examination to a maximum period of three hours, and in submitting case records at this time all candidates' case abstracts whose obstetric reports do not include measurements either by calipers and, as indicated, by acceptable x-ray pelvimetry will be considered incomplete. Prospective applicants or candidates in military service are urged to obtain from the office of the secretary a copy of the "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards," which will be supplied on request. This record was compiled by the Advisory Board for Medical Specialties and is approved by the Offices of the Surgeons General, having been recommended to the services in circular letter number 76 from the War Department Army Service Forces and referred to as the Medical Officer's Service Record. These will enable prospective applicants and candidates to keep an accurate record of work done while in military service and should be submitted with the candidate's application, so that the credentials committee may have this information available in reviewing the application. Applications and bulletins of detailed information regarding the board requirements will be sent on request to Dr. Paul Titus, secretary, 1015 Highland Building, Pittsburgh 6, Pa. Applications must be in the office of the secretary by November 15, ninety days in advance of the examination date. The time and place of the spring 1945 (part II) examinations will be announced later.

CORRECTION

Studies in Prothrombin.—In the article by Shapiro with this title in THE JOURNAL June 24, in the first paragraph under "Results" on page 547 the dosage of acetylsalicylic acid should have been 6 Gm. instead of 6 mg., as given.

Government Services

Lanham Funds for Child Care

A total of \$221,403 Lanham Act funds has been allocated by the Federal Works Agency to seventeen "war impacted" localities in twelve states to carry on child care, recreation and school services. The projects are located in California, Colorado, Georgia, Kentucky, Michigan, Montana, New Hampshire, New Jersey, New York, Ohio, Oregon and Washington.

Marian Russell Named Medical Social Consultant

Marian E. Russell, executive secretary of the American Association of Medical Social Workers, has been appointed medical social consultant in the office of vocational rehabilitation, Federal Security Agency. Miss Russell will aid in the formulation and development of the medical social aspects of the vocational rehabilitation program, especially as they relate to the physical restoration of disabled persons. She will provide consultant and technical services for the federal office and for the state divisions of vocational rehabilitation and the state agencies for the blind.

Dr. Daily Leaves Health Service Division

Dr. Edwin F. Daily, director of the division of health services of the Children's Bureau, U. S. Department of Labor, has been granted leave to serve with the Army of the United States to assist in reestablishing civilian medical and hospital services in some of the liberated countries. Dr. Abram L. Van Horn has been appointed director of the division of health services and Dr. Betty Huse has been named to succeed Dr. Van Horn as assistant director for crippled children in the division. Dr. Daily has been in charge of the emergency maternity and infant care program administered by the Children's Bureau, under which medical, nursing and hospital care are given servicemen's wives and infants. Dr. Van Horn graduated at the University of Michigan Medical School, Ann Arbor, in 1928 and before joining the Children's Bureau in 1936 served as chief of the bureau of child hygiene of the Ohio Department of Health. Dr. Huse has been associated with the division of health services since 1939.

Additional Fellowships for Health Education Available

The U. S. Public Health Service announces that, through the cooperation of the National Foundation for Infantile Paralysis and the W. K. Kellogg Foundation, additional fellowships for health education are now available for qualified men of certain Selective Service classifications as well as for women. Funds for the fellowships have been made available through the National Foundation for Infantile Paralysis, Inc., and the W. K. Kellogg Foundation for the collegiate fall term of 1944. The fellowships have been established to meet the present and future needs for trained health educators in schools, communities and local, state and federal health departments. Women between the ages of 19 and 40 inclusive who are United States citizens and men who are United States citizens, 30 years or over, or whose Selective Service classification is 4F or 1AL, and who possess a bachelor's degree from a recognized college or university may apply. Candidates should have a skilful knowledge of the use of the English language, courses in the physical and biologic sciences, social sciences, education and educational psychology plus the ability to work effectively with people. Fellowships will lead to a master of science degree in public health. They will provide for twelve months' training in public health education, three months of which will be supervised field experience; \$100 a month for twelve months, full tuition and travel. Training will be given either at the University of North Carolina, Yale University or University of Michigan. Forms for application for fellowships may be obtained from the Surgeon General, U. S. Public Health Service, Washington 14, D. C. Applications must be accompanied by a transcript of college credits and a small photograph and must be in the office of the Surgeon General not later than August 15.

Penicillin in the Treatment of War Wounds

For the guidance of those who treat battle casualties, the Penicillin Clinical Trials Committee of the Medical Research Council has prepared a memorandum. It points out that penicillin has three properties which make it an ideal antiseptic: it inhibits the growth of bacteria in extremely high dilutions, it has almost no toxicity and its action is unimpaired by serum, blood or pus. No other substance has these qualities in anything like the same degree, and clinical trials are fully in accord with the expectations aroused. Applied locally, it is immensely superior to the sulfonamides as an antiseptic for three reasons: it is a much more potent bacteriostatic, it acts efficiently on large as well as small quantities of bacteria and its action is not inhibited by pus. It also is used systemically. A solution is injected intravenously or intramuscularly, with the object of maintaining a bacteriostatic concentration in the blood. This treatment may be necessary for extensive and deep seated infections and for septicemia, but under present conditions it should not be used if the responsible organism is susceptible to sulfonamide treatment.

The action of penicillin on bacteria is highly selective. Gram positive cocci (*Staphylococcus aureus*, *Streptococcus pyogenes*, other streptococci except enterococcus, and pneumococcus), Clostridia, *Neisseria*, *Bacillus anthracis* and *Corynebacterium diphtheriae* are susceptible. *Proteus vulgaris*, *Pseudomonas aeruginosa*, the coli-typhoid-dysentery group, *Pasturella*, *Brucella*, *Haemophilus*, *Enterococcus* and the tubercle bacillus are insusceptible. From the point of view of wound treatment the principal pyogenic cocci and the whole of the gas gangrene group are highly susceptible, while all gram negative bacteria, except gonococci and meningococci, are resistant. The only common pathogens among the gram negative are *Proteus*, *Pseudomonas aeruginosa* and coliform bacilli.

The local application of penicillin through a tube inserted into the wound is the best and least wasteful method. In most cases the solution should be injected at twelve hour intervals. Open wounds may be sprayed, although the use of a powder or cream is generally preferred. Penicillin in a strength of 1,000 to 5,000 units per cubic centimeter has been injected into abscess cavities following aspiration of pus. Penicillin cream may be used for surface wounds which cannot be closed or for skin infections. Penicillin powder may also be used for wounds which cannot be closed, or it may be applied preparatory to closure.

Malnutrition and Disease in India

The physiologist A. V. Hill, F.R.S., has returned from a mission to India. In a letter to the *Times* he deals with nutrition and disease in that country. He says that there has been much fruitless recrimination about the recent famine in Bengal and that instead of arguing about the symptoms we should face the facts. The mortality in India at all ages is four to eight times ours; the expectation of life at birth is 26 years against our 62; one half those born reach 22 years against 69 per cent with us. Ill health is correspondingly prevalent; between 100 and 200 millions out of nearly 400 suffer from malaria every year. Tuberculosis, cholera, smallpox, plague, guinea worm and filarial infection, yaws, kala-azar and many other diseases take their toll of life and health. A large part of the population—according to any reasonable standard more than half—is underfed. Of these many millions live on the verge of starvation. Chronic malnutrition acts with disease in a vicious circle. In spite of all this the population of India

increases by 6 million annually, or at the rate of about 16 per thousand. There is nothing new in this malnutrition and disease in India. Indeed, the present population trend indicates that the effect is less than it has been in the past. The population has increased from 280 millions in 1900 to 389 millions at the last computation. This increase has been steady except for a drop in 1918-1919 due to an epidemic of influenza—a striking example of the effect of disease on a chronically underfed population.

Already about 50 per cent more food is required in India, Professor Hill states. He asks "Can agriculture by present methods catch up and cope with the expanding population?" He thinks it is idle to talk of family limitation except as a long term policy, and the present need is acute. The factor of safety in India is very low. Disorganization or disorder would lead to a frightful tragedy. Cooperation of all men of good will in the wholehearted development of India's resources by modern, scientific methods is the only hope of averting disaster, Professor Hill believes. It might be added that India is a striking example of the truth of the doctrine of Malthus, which it is the fashion in some quarters to scoff at just now. Malthus taught that population always tends to outgrow the means of subsistence and if not checked by prudent means must be checked by the positive means of famine and disease. British rule has provided a safety of life unknown previously in India and has introduced modern methods of industry in some places. The result has been a great increase of population, but for this very reason the malnutrition of the vast millions could not be mitigated.

Speed in Treatment of the Wounded

On June 6, the opening day of the landing of allied troops in France, some casualties were already back in Britain. The speed with which the wounded are succored has often been noted as a noteworthy feature of this war. For example, it is claimed that in North Africa the lives of at least 5,000 wounded were saved by one thing only—speed. There was speed in picking them up when they were hit, speed in getting them to a first aid station, speed in getting them to the hospital and speed in getting them to a base. A few hundred yards behind the line is the regimental aid post. Here are medical officers and trained orderlies. If blood transfusion is necessary, it can be done here. Even an operation can be performed if necessary. Usually, however, the wounded man is given an injection of morphine and within thirty minutes is 2 miles back at a field dressing station. This is usually a sandbagged, canvas shelter, but it may be set up in a commandeered building. Its equipment is carried on a 3 ton lorry. There are two medical officers and five assistants. Antitetanus injections, blood transfusion or saline and dextrose injections are done here, and even after major operations can be performed. In close radio contact is the field ambulance with at least half a dozen beds. The wounded man does not stop here long but is taken to the casualty clearing station about 20 miles behind the line, which he reaches in not more than two hours from the time he is hit. Here the diagnosis is finally established and he is scheduled for resuscitation, operation or further evacuation. From the casualty clearing station he goes to the general hospital, established at a railhead either in a commandeered building or in a marquee. Here all the resources of medical science, including x-rays, are available. In case of urgency he may travel to the general hospital by air. However he travels, he is nursed on the way, usually by women.

The Treatment of Gas Gangrene

As fighting extends in Europe, gas gangrene becomes a more likely complication of wounds. The Army Medical Department has therefore issued to every medical and dental officer a bulletin laying down the treatment to be followed in the light of the important experience gained in the present

war. Gas gangrene may follow trivial injuries but is most likely in cases of interference with the main blood supply of a limb, extensive laceration of muscle, particularly of the thigh, buttock or shoulder, compound fracture of the long bones, especially of the lower limb, foreign bodies carried deeply, prolonged application of a tourniquet or tight packing, application of a tight plaster or even a tight dressing to an inadequately excised wound and delay in surgical treatment. In all such cases the following prophylaxis is laid down: Polyvalent gas antitoxin 22,500 units, with the usual dose of tetanus antitoxin, should be injected intramuscularly in forward medical units, but when intravenous administration is practicable it is preferable. The usual sulfonamide medication should be followed both locally and by mouth. But wound excision is the most important prophylactic and should never be unnecessarily delayed.

If gas gangrene is established, speed is essential to save life. Preoperative measures consist of (1) a dose of 60,000 units of polyvalent gas gangrene antitoxin given intravenously by syringe (if the toxemia is very severe 100,000 units should be given); (2) sulfathiazole 3 Gm., which may be given during transfusion, and (3) transfusion of 1 or 2 pints of blood. Occasionally blood may be contraindicated; in such cases, or if blood is not available, plasma may be given. As a general rule if the patient is too ill for operation he is unlikely ever to be in a better condition than following administration of 100,000 units of antitoxin in 1 or 2 pints of blood.

Removal of the infection by complete excision of the affected tissues is essential. Amputation is by no means a routine necessity, though frequently it is inevitable because of vascular damage. Where only one muscle or one group of muscles is involved, that muscle or group should be extirpated from origin to insertion. Great care must be taken not to damage the blood supply to adjacent muscles. If radical surgery is impossible, either because of the site of infection or because of the condition of the patient, the muscle sheaths and muscles must be freely incised to relieve tension, and intensive therapy with antitoxin and drugs pursued. The best anesthetic is a small dose of pentothal sodium followed by nitrous oxide and oxygen. Chloroform and ether must be avoided. From necessarily limited experience, it seems that penicillin will prove of great value in the treatment of gas gangrene. The initial dose should be at least 30,000 units of sodium penicillin intramuscularly. Three hours later it should be given at the rate of 5,000 to 6,000 units by intravenous drip.

Nutrition Research Unit for the British Colonies

With the object of improving the health of the British colonial peoples a research organization has been formed in London. It is called the Human Nutrition Research Unit, and it has been established by the Medical Research Council with Dr. B. S. Platt as director. The unit is already engaged in important investigations affecting colonial nutrition and is offering hospitality for study and research to nutrition workers from the colonies. It will soon be ready to advise colonial governments on technical questions. The formation of the unit is regarded as only the first step toward a wider organization, which, it is hoped, will include in its scope both teaching and research and will cooperate closely with workers in the colonial dependencies.

Penicillin Workers Honored by the Government

Alexander Fleming, F.R.S., professor of bacteriology at the University of London, discoverer of penicillin, and H. W. Florey, professor of pathology at Oxford University, developer of the use of penicillin in medicine, have been knighted for their services to medical science.

BOLIVIA

(From Our Regular Correspondent)

May 6, 1944.

United States Cooperation with Bolivian Health Service

Under the direction of Dr. George Bergman of Los Angeles the Servicio Cooperativo Interamericano de Salud Publica, organized by the coordinator for inter-American affairs, is cooperating directly with the Bolivian health minister to carry on a vast public health program throughout Bolivia. In 1942 and 1943, \$1,000,000 was made available to support the Bolivian health program; this amount is 60 per cent of the whole Bolivian health budget for a year. The service bought a large building in the center of La Paz to establish besides its own offices a public health center, a training center for nurses, a large conference room and offices for the Ministry of Health. Already an important health center is being conducted in the overcrowded suburb Villa Victoria, where sanitary work is of utmost importance because of a lack of sewerage facilities, unhygienic dwellings and lack of doctors. The nurses there gave excellent service during the last typhoid epidemic by large scale vaccination. Assistance with a training school for nurses is being given in La Paz. In Bolivia's second largest town, Cochabamba, a health center is operating and a large central laboratory is nearing completion. In the tropical Beni district the service is operating a provisional 10 bed hospital. In Guayaramerin, on the Brazilian border, a temporary 12 bed hospital is being operated at the present time. In both Riberalta and Guayaramerin modern hospitals of 30 and 20 beds respectively are in process of construction. The service owns four river boats in the Amazonas district, providing medical attention to these important rubber producing regions. In the same district it cooperates also with the U. S. owned Rubber Development Company in providing doctors and sanitary engineers for this essential production. Also it controls the medical services and hospitals in several mines in the Cordillera region.

Direct cooperation with local physicians is effected by offering vaccines and drugs that are hard to get and also educational films on tuberculosis, venereal diseases, cancer and other public health problems.

The servicio has been operating only a year and a half and plans to build other health centers, one in a suburb of La Paz and others in the district capitals Oruro and Potosi. It also plans to assist in a nurse's training school in Cochabamba.

The personnel of the service is composed of Bolivian as well as some foreign and especially American practitioners and employees.

Of utmost importance is the servicio's large scale sanitation program in the vast malaria infested regions and a more effective control of communicable diseases such as typhus, typhoid, relapsing fever, whooping cough, variolosis and leprosy.

A number of scholarships have been offered and granted to various doctors and other persons by the Health and Sanitation Division of the Coordinator's Office in Washington, D. C., and some of these have already entered their specialized training. The Bolivian minister for health and labor has left for a Washington, D. C., health conference to increase cooperation.

Marriages

CHARLES RICHARD BATES JR., Shreveport, La., to DR. HARRIET ANN HEGAR of Edinburg, Texas, in El Paso, May 19.

GEORGE CONWELL SMITH JR., Kaufman, Texas, to Miss Frances Grisham in Memphis, Tenn., June 14.

WILLIAM M. LA ZEBNIK, Jackson, Mich., to Miss Mayda Chosed of Merrick, L. I., N. Y., in March.

Deaths

J. A. M.
July 29, 1931

William E. Parke ☉ Miami Beach, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1886; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the Medical Society of the State of Pennsylvania; past president of the Obstetrical Society of Philadelphia and of the Association of Ex-Residents and Resident Physicians of the Philadelphia General Hospital; fellow of the American College of Surgeons and the College of Physicians of Philadelphia; served on the staffs of the Hospital of the Protestant Episcopal Church, Frankford Hospital, Presbyterian Hospital, St. Mary's Hospital, Kensington Hospital for Women and the Northern Dispensary, Philadelphia, died June 26, aged 82.

Henry Barnard Hitz ☉ Milwaukee; Columbian University Medical Department, Washington, D. C., 1891; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; formerly professor of laryngology and rhinology at the Wisconsin College of Physicians and Surgeons; an adjutant at the Milwaukee Base Hospital number 22 near Bordeaux, France, during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; on the staffs of the Columbia and Milwaukee Children's hospitals; vice chief of staff, Milwaukee Hospital, where he died April 6, aged 76, of coronary occlusion and general arteriosclerosis.

Charles Bradley Pinkham, San Francisco; New York Homeopathic Medical College and Hospital, New York, 1899; member of the California Medical Association; retired Feb. 1, 1943 as secretary-treasurer of the California State Board of Medical Examiners, a position he had held since 1913; served as a member of the board; in 1930 president of the Federation of State Medical Boards of the United States; at one time professor of anatomy at the Hahnemann Medical College of the Pacific; formerly chief surgeon of the San Francisco emergency hospitals; died at his home in Atherton, Calif., July 14, aged 71.

John Reid Andrews, Bedford, Ind.; Kentucky School of Medicine, Louisville, 1892; for one term mayor; county clerk of Lawrence County for eight years; secretary of the chamber of commerce; a charter member, past president and secretary of the Kiwanis Club; died May 25, aged 72, of chronic myocarditis.

James Aloysius Barrett, New Bedford, Mass.; Maryland Medical College, Baltimore, 1910; member of the Massachusetts Medical Society and the New England Roentgen Ray Society; died in St. Luke's Hospital April 28, aged 58, of coronary thrombosis.

William Lee Bishop, Portland, Ore.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; member of the Oregon State Medical Society; formerly editor of the *Medical Sentinel*; died in the Hahnemann Hospital April 26, aged 71, of hypertensive cardiorenal disease and encephalopathy.

John Charles Bowman, Genoa, Ohio; Columbus Medical College, 1890; died May 30, aged 81, of coronary disease.

Ervin Davis Brooks, Kalamazoo, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1885; member of the Michigan State Medical Society; died in the Kalamazoo State Hospital April 14, aged 89.

Alexander Eugene Burke ☉ Philadelphia; Georgetown University School of Medicine, Washington, D. C., 1918; diplomate of the National Board of Medical Examiners; fellow of the American College of Surgeons; formerly member of the state board of medical education and licensure; served in the medical corps of the U. S. Navy during World War I; gynecologist, St. Joseph's Hospital from 1929 to 1935 and later surgeon; chief surgeon, Fitzgerald-Mercy Hospital, Darby, Pa., and St. Agnes Hospital; died May 19, aged 48.

Martin Loren Cantrell, Marked Tree, Ark.; University of Tennessee College of Medicine, Memphis, 1931; member of the Arkansas Medical Society; served as secretary of the Craighead-Poinsett Counties Medical Society; surgeon for the Frisco Railroad; died in the Baptist Memorial Hospital, Memphis, Tenn., April 19, aged 39, of nephritis and cardiovascular disease.

Archie F. Caraway, Gulfport, Miss.; Mississippi Medical College, Meridian, 1910; on the staff of the King's Daughters' Hospital; died May 17, aged 63, of postencephalitic complications.

Edgar Christy ☉ Glenwood, Iowa; University of Nebraska College of Medicine, Omaha, 1907; life member of the Iowa State Medical Society; past president of the Mills County Medical Society; a captain in the medical corps of the U. S. Army during World War I; a member of the medical reserve corps on the staff of the Jennie Edmundson Memorial Hospital, Council Bluffs; since 1941 assistant superintendent of the Glenwood State School; died July 5, aged 63, of coronary occlusion.

Edwin Davis ☉ Fort Worth, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, Fort Worth, 1911; president of the Tarrant County Medical Society in 1923; one of the first members of the Children's Hospital staff and once a member of the staff of a number of hospitals in Fort Worth; for many years served as chief of staff of the department of gynecology at the City-County Hospital; a member of the Kiwanis Club; died April 6, aged 69, of pulmonary embolism due to suppurative pneumonitis.

John Clayton Davis, Little Rock, Ark.; Memphis (Tenn.) Hospital Medical College, 1903; member of the Arkansas Medical Society; assistant professor of neuropsychiatry at the University of Arkansas School of Medicine; served as president of the Poinsett County Board of Health; for many years on the staff and at one time superintendent of the State Hospital; died April 30, aged 71, of coronary disease.

Frank Adams Ewers, Akron, Ohio; Jefferson Medical College of Philadelphia, 1905; member of the Ohio State Medical Association; died March 9, aged 65.

Leon Feingold, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; died in the Grant Hospital April 12, aged 64.

Charles H. Fulbright, St. James, Mo.; Missouri Medical College, St. Louis, 1889; member of the Missouri State Medical Association; died April 18, aged 78, of chronic hypertension.

Sydney Ormond Goldan ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1896; died April 23, aged 74.

Donald Alexander Graham ☉ Denver; University of Nebraska College of Medicine, Omaha, 1923; examining physician for draft board number 9; on the staffs of the Presbyterian and St. Anthony's hospitals; died April 21, aged 48, of coronary occlusion.

Rudolph Melvin Gunderson, Lake Park, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1907; company physician for the local division of the Northern Pacific Railway; died April 2, aged 64, of heart disease.

Charles Reginald Hargrove, Marshall, Texas; University of Louisiana Medical Department, New Orleans, 1883; honorary member of the State Medical Association of Texas; past president of the Harrison County Medical Society and the Tri-State Medical Society; a member of the council of defense during World War I; served as city health officer and as local surgeon of the Gulf Coast and Santa Fe Railway; died March 26, aged 84, of heart disease.

Paul Douglas Hayman ☉ Huntington, W. Va.; Medical College of Virginia, Richmond, 1932; served an internship and later a residency at the White Cross Hospital, Columbus, Ohio; died May 1, aged 36, of glioma.

Albert E. Holley, St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1897; member of the Missouri State Medical Association; served as county physician and county health officer; on the staffs of St. Joseph's Hospital and the Missouri Methodist Hospital, where he died April 28, aged 79, of carcinoma of the pylorus and stomach.

Nathan Asbury Hughes, St. Louis; Hospital Medical College, Eclectic, Atlanta, 1910; died April 29, aged 66, of heart disease.

Herbert Shattuck Johnson, Stoneham, Mass.; Harvard Medical School, Boston, 1883; formerly practiced in Malden, where he was a trustee of the Malden Library, school physician and on the staff of the Malden Hospital; associated with the E. L. Patch Company, manufacturers of pharmaceutical supplies; died April 29, aged 87, of uremia.

John M. F. Keaney, Louisville, Ky.; University of Louisville Medical Department, 1895; member of the Kentucky State Medical Association; county coroner; died in St. Joseph Infirmary March 5, aged 68.

Charlie A. Kelley, Lilburn, Ga.; Atlanta College of Physicians and Surgeons, 1909; died in an Atlanta hospital March 18, aged 71, of subarachnoid hemorrhage.

Edward Brown Kinder, St. Louis; St. Louis College of Physicians and Surgeons, 1891; formerly professor of bacteriology, pathology and histology at his alma mater; found dead in bed May 29, aged 79, of coronary sclerosis.

Charles Albert Kittredge, Beacon, N. Y.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; died May 23, aged 72, of coronary thrombosis.

Frederick Herman Koepke, Watsonville, Calif.; Cooper Medical College, San Francisco, 1903; member of the California Medical Association; died May 18, aged 63, of heart disease.

William Steven Lacy, Jacksonville, Texas; Vanderbilt University School of Medicine, Nashville, 1883; past president of the Smith County Medical Society; died April 4, aged 85, of acute cardiac dilatation.

Oscar Bernhardt Lambert, Milwaukee; Northwestern University Medical School, Chicago, 1907; died in the Columbia Hospital May 31, aged 62, of carcinoma of the left lung.

Regina Ledbetter, Clarksville, Tenn.; University of Tennessee College of Medicine, Memphis, 1941; served an internship at the Women and Children's Hospital, Chicago; died May 12, aged 28, of rheumatic heart disease.

Arthur Lester, New York; Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Prussia, Germany, 1921; resident physician at the Sunnyside Hospital, Staten Island, where he died May 8, aged 50, of heart disease.

Victor Fawcett Long, La Porte, Ind.; Rush Medical College, Chicago, 1914; died in Fairview Hospital, May 7, aged 54, of pulmonary embolism after amputation of the leg.

Thomas F. Loughlin @ Hartford, Wis.; Marquette University School of Medicine, Milwaukee, 1915; served during World War I; died in St. Mary's Hospital, Milwaukee, March 17, aged 55, of coronary occlusion.

John Francis Lowney @ Fall River, Mass.; Tufts College Medical School, Boston, 1900; elected president of the Fall River Medical Society in 1907; died February 19, aged 71, of chronic interstitial nephritis and coronary sclerosis.

Frederick Livingstone MacDonald @ Waltham, Mass.; University of Vermont College of Medicine, Burlington, 1907; formerly instructor in otolaryngology at the Tufts College Medical School, Boston; for two terms mayor of Waltham; served on the staffs of the Boston City Hospital and Massachusetts General Hospital, Boston, and the Waltham Hospital; died May 24, aged 65, of carcinoma of the stomach.

John Allen McGee, Virginia, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1896; member of the Illinois State Medical Society; past president and secretary of the Cass County Medical Society; served as president of the local board of health; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; on the staffs of the Memorial and St. John's hospitals, Springfield, and the Passavant Memorial Hospital, Jacksonville; died May 6, aged 71, of coronary thrombosis.

Charles A. McNeil @ Sedalia, Mo.; St. Louis University School of Medicine, 1905; formerly on the staff of the Missouri, Kansas and Texas Railroad Hospital; served as president of the Union Savings Bank; died May 17, aged 68, of coronary embolism.

Max Mahrer @ Cleveland; Western Reserve University School of Medicine, Cleveland, 1917; served during World War I; died May 3, aged 50, of coronary thrombosis.

Emil Maisner, New York; Long Island College Hospital, Brooklyn, 1894; at one time member of the board of health of Union Hill, N. J.; at one time on the staff of the North Hudson Hospital, Weehawken, N. J.; died in the Fordham Hospital May 14, aged 77, of pneumonia and heart disease.

Olin May, Lubbock, Texas; Medical Department of Grant University, Chattanooga, Tenn., 1894; died March 12, aged 83, of cerebral hemorrhage.

William May, Farber, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1880; died in the Pike County Hospital, Louisiana, April 22, aged 93, of myocarditis.

John Bertrand Meury @ Brooklyn; Long Island College Hospital, Brooklyn, 1896; formerly on the staffs of the Eastern District Trinity and Bushwick hospitals; died in the Eye and Ear Hospital May 13, aged 71, of uremia and heart disease.

Leo Clement Mundy @ Wilkes-Barre, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; fellow of the American College of Surgeons; state senator;

at one time Democratic county chairman and collector of internal revenue for the middle district of Pennsylvania; served overseas during World War I; received the Distinguished Service Cross for heroism in caring for wounded soldiers under heavy enemy fire; chief, surgical staff, Mercy Hospital, where he died June 11, aged 57, of coronary occlusion.

Hildus Augustinus O. Nass @ Mabel, Minn.; State University of Iowa College of Medicine, Iowa City, 1898; died in the Lutheran Hospital, La Crosse, Wis., March 27, aged 72, of gastric carcinoma.

Clement Channing Nevin, Edgartown, Mass.; Yale University School of Medicine, New Haven, 1908; served as acting assistant surgeon in the U. S. Public Health Service; died March 12, aged 61, of acute hepatitis and chronic osteomyelitis of the tibia.

Isaac Otis Newell, Milwaukee; Rush Medical College, Chicago, 1892; died April 7, aged 75, of coronary occlusion.

Deno Francis O'Connor, Chicago; Loyola University School of Medicine, Chicago, 1917; member of the Illinois State Medical Society; formerly clinical assistant and clinical associate in otolaryngology at his alma mater; fellow of the American College of Surgeons; on the senior staff of the Mercy Hospital; served during World War I; died in the Madison General Hospital, Madison, Wis., April 18, aged 52, of cirrhosis of the liver.

John Jay Ogg, Marshall, Minn.; Barnes Medical College, St. Louis, 1903; died March 22, aged 86, of cardiovascular degeneration.

Daniel Joseph O'Loughlin @ Kankakee, Ill.; Northwestern University Medical School, Chicago, 1904; on the staff of St. Mary's Hospital, where he died May 8, aged 63, of hypertensive heart disease and anterior wall infarction.

William Wallace Osgood, Muskogee, Okla.; Cleveland University of Medicine and Surgery, 1896; served as a member of the state board of medical examiners; died in Fort Smith, Ark., March 6, aged 74, of heart disease.

James Wight Packard @ Rockton, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; formerly on the staff of the Wesley Memorial Hospital, Chicago; died in the Municipal Hospital, Beloit, Wis., May 24, aged 80, of cerebral arteriosclerosis.

Mary McDermott Penny, Saugus, Mass.; Tufts College Medical School, Boston, 1910; member of the Massachusetts Medical Society; formerly chairman of the public health commission; on the courtesy staff of the Lynn Hospital, Lynn; one of the Saugus school physicians; medical examiner for women at the Y. W. C. A.; died in Falmouth April 17, aged 73, of heart disease.

Edward Henry Peterson @ Grand Junction, Colo.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1919; served as county physician; formerly member of the staff and secretary of St. Mary's Hospital; died April 13, aged 63, of coronary thrombosis and pneumoconiosis.

Frank Sibbald Pike, Detroit; University of Louisville (Ky.) Medical Department, 1910; at one time secretary of the Toombs County (Ga.) Medical Society; for many years associated with Parke, Davis & Company; died in the Henry Ford Hospital May 2, aged 54, of cerebral hemorrhage.

James Kells Pollock, South Mountain, Pa.; Jefferson Medical College of Philadelphia, 1928; resident physician at the Pennsylvania State Tuberculosis Sanatorium number 1, where he died April 29, aged 42, of pulmonary tuberculosis.

Francis James Pomainville, Wisconsin Rapids, Wis.; Marquette University School of Medicine, Milwaukee, 1929; died March 21, aged 42, of injuries received in an automobile accident.

Marion Henderson Powers @ Weirton, W. Va.; Jefferson Medical College of Philadelphia, 1907; served overseas with Base Hospital number 14 during World War I and was discharged with rank of captain; a member of the staffs of the Ohio Valley and Gill Memorial hospitals, Steubenville, Ohio; died at McCaza, Que., Canada, May 4, aged 62, of coronary thrombosis.

Hal Henslee Puckett, Alice, Texas; Memphis (Tenn.) Hospital Medical College, 1910; member of the State Medical Association of Texas and the Texas Public Health Association; past president of the West Virginia Public Health Association; formerly director of the Fayette County Health Unit in Fayetteville, W. Va.; director of the Jim Wells-Duval County Health Unit; served as director of the health units of Floyd, Tom Green and Bowie counties; died April 15, aged 59, of coronary occlusion.

Fletcher Stanhope Pyle, San Francisco; College of Physicians and Surgeons of San Francisco, 1905; on the staffs of St. Mary's Hospital and St. Joseph's Hospital, where he died April 10, aged 73, of generalized arteriosclerosis, hemiplegia and myocarditis.

John Harrison Quayle, Miami, Fla.; Cleveland University of Medicine and Surgery, 1895; University of Wooster Medical Department, Cleveland, 1904; a life member of the Cleveland Chamber of Commerce; died in St. Francis Hospital April 25, aged 69, of carcinoma of the head of the pancreas.

Charles E. Rariden, Bedford, Ind.; Kentucky School of Medicine, Louisville, 1880; member of the Indiana State Medical Association; died in Dalton, Ga., April 29, aged 87, of coronary thrombosis.

Carrie Turner Reid, Indianapolis; Indiana Medical College, School of Medicine of Purdue University Indianapolis, 1906; died in the Methodist Hospital May 11, aged 65, of intestinal obstruction.

Robert Noel Ritchie Ⓢ Rochester, N. Y.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1918; associate professor of obstetrics and gynecology at the University of Rochester School of Medicine and Dentistry; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; at one time superintendent of the Montreal Maternity Hospital and on the staff of the Royal Victoria Hospital, Montreal; on the staff of the Strong Memorial Hospital, where he died May 8, aged 49, of heart disease.

Monte Valient Robinson, Chicago; St. Louis College of Physicians and Surgeons, 1918; veteran of the Spanish-American War; a first lieutenant in the medical corps, U. S. Army, in 1918 and a captain in the officers reserve corps, U. S. Army, in 1919; owner of a clinical laboratory; died May 11, aged 64, of carcinoma of the liver.

Ola Raymond Rooks Ⓢ Trenton, Mo.; University Medical College of Kansas City, Mo., 1909; past president of the Grundy-Daviess Counties Medical Society; president of the board of education; county health officer; formerly on the staff of the State Hospital number 3, Nevada; served as president of the Kiwanis Club; president of the staff of the Wright Memorial Hospital, where he died April 5, aged 57, of acute coronary thrombosis.

Samuel Rothenberg, Newark, N. J.; Long Island College Hospital, Brooklyn, 1916; member of the Medical Society of New Jersey; fellow of the American College of Surgeons; died April 29, aged 51.

Forrest Grimm Schaeffer Ⓢ Allentown, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; fellow of the American College of Surgeons; chief of the department of obstetrics, Allentown Hospital; died May 10, aged 61, of coronary occlusion.

George Henry Scott, Boston; Tufts College Medical School, Boston, 1909; died March 24, aged 65.

George C. Smith, Poseyville, Ind.; Jefferson Medical College of Philadelphia, 1891; member of the Indiana State Medical Association; died in the Welborn-Baptist Memorial Hospital, Evansville, May 2, aged 80, of pneumonia and angina pectoris.

Elmer Leslie Smythe Ⓢ Pasadena, Calif.; California Eclectic Medical College, Los Angeles, 1914; member of the Washington State Medical Association; formerly with the Civilian Conservation Corps in Sanger, Capitola and Yosemite National Park; served on the staff of the U. S. Veterans Hos-

pital number 59 in Tacoma, Wash.; died in the Veterans Administration Facility, West Los Angeles, April 19, aged 61, of carcinoma of the right kidney and bronchopneumonia.

Clarence Richard Spradling, Hallam, Neb.; Eclectic Medical College, Cincinnati, 1916; member of the Nebraska State Medical Association; on the staff of St. Elizabeth Hospital, Lincoln; died April 22, aged 53, of carcinoma.

Farkas Wolfgang Steiner Ⓢ Akron, Ohio; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1912; a medical officer in the Hungarian army during World War I; on the staffs of St. Thomas, Peoples and City hospitals; president of the Zionist Organization of America; died May 5, aged 56, of carcinoma.

Marion Russell Thomas, Savannah, Ga.; University of Maryland School of Medicine, Baltimore, 1902; member of the Medical Association of Georgia; chief surgeon of the Southern Railway and local physician for the Metropolitan Life Insurance Company; president of the staff of Oglethorpe Sanatorium, where he died April 8, aged 66, of carcinoma.

Jacob Hawkins Tucker, Kansas City, Mo.; Kansas City College of Medicine and Surgery, 1923; died in the Kansas City General Hospital April 29, aged 76, of bronchopneumonia.

George T. Veal, Dallas, Texas; University of Louisville (Ky.) Medical Department, 1883; at one time mayor of Roswell, N. M., and member of the legislature; died in Fabens April 22, aged 83, of pulmonary hemorrhage and thrombosis.

Claude Ebenezer Ward, Hartland, Vt.; University of Louisville (Ky.) Medical Department, 1905; served during World War I; died in the Mary Hitchcock Hospital, Hanover, N. H., April 26, aged 67.

Edgar Kirby Ward, Oakland, Calif.; College of Physicians and Surgeons of San Francisco, 1902; Northwestern University Medical School, Chicago, 1908; member of the California Medical Association; on the staff of the East Oakland Hospital; died April 26, aged 72, of coronary disease.

Mary Rhoda Wetmore, Allegan, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1898; died in the Allegan Health Center April 13, aged 74.

KILLED IN ACTION

Frank James Kolumbar Jr., Berwyn, Ill.; Chicago Medical School, 1942; served an internship at the North Chicago Hospital, Chicago; commissioned a first lieutenant in the medical corps, Army of the United States, on Oct. 12, 1942; killed in action in the Marshall Islands February 21, aged 29.

Arthur William Wilkinson, Phoenix, Ariz.; Harvard Medical School, Boston, 1938; diplomate of the National Board of Medical Examiners; served an internship and residency at St. Luke's Hospital in Chicago; commissioned a lieutenant (jg), medical corps, U. S. Naval Reserve; began extended active duty on Sept. 22, 1941; later promoted to lieutenant; for meritorious service in the line of duty received the Order of the Purple Heart; aged 31; killed in action when the U. S. S. *Sims*, a destroyer on which he was serving, was lost in the Battle of the Coral Sea, May 7, 1942; previously reported missing in action; presumptive date of death by Navy Department is May 8, 1943.

LIEUT. FRANK J. KOLUMBAR JR.,
M. C., A. U. S., 1914-1944

LIEUT. ARTHUR W. WILKINSON
(MC), U.S.N.R., 1911-1943

Bureau of Investigation

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 increased the Food and Drug Administration's control of the advertising claims and statements made on the label of a medicine or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual, manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable. In some cases the claims cited have been discontinued by the firms several months (or even longer) before the issuance of the order. Abstracts of some of the orders issued in 1943 follow in this form: name of product, name of distributor, date of issuance of complaint, date of issuance of Cease and Desist Order and terms of order.

Kola Astler.—Kola Astier Corporation and Gallia Laboratories, Inc., both of New York; complaint issued Jan. 31, 1942; order issued June 26, 1943. Order directed the respondents to discontinue the following advertising misrepresentations: That their product is of value in treating any disorder or condition resulting from exhausted nerves, other than that afforded by a mild, temporary stimulant; that it is a tonic and will restore lost energy; that it is a competent or effective treatment for poor digestion or insomnia; that it has any reliable effect on heart action or the circulatory system, or that its diuretic action is sufficient to activate the liver and kidneys. The Commission reported that the only active ingredient in Kola Astier is caffeine, and that its value is limited to that of a temporary stimulant, and only to the extent of the stimulating effect obtained from a cup of coffee.

Merlek.—Michael E., Myron E. and Kenneth L. Lee, trading as Leesons and as Merlek, Alameda, Calif.; complaint issued Nov. 15, 1942; order issued Oct. 27, 1943. Order directed respondents to discontinue any advertisement which represented that 90 per cent or any substantial percentage of diseases or ailments are due to a deficiency of minerals in the body; that Merlek corrects mineral imbalance or is the natural source of minerals; that it constitutes a cure or remedy for, or offers any value in the treatment of, prostaticitis, eczema, rickets, headache, Bright's disease, high and low blood pressure, stomach and heart trouble, indigestion, diabetes, bronchitis, arthritis, rheumatism, cancer, asthma, goiter, anemia, cataracts, and the many other diseases or ailments mentioned in their advertisements, or any other ailment or condition of the body. The Commission reported that Merlek had been found to be nothing but filtered sea water, to which was added at one time a quantity of potassium iodide.

Nash's C & L Malaria Chill Tonic and Laxative.—William G. Nash, Sr., William G. Nash, Jr., and Florence Nash Cox, trading as Nash Brothers Drug Company, Jonesboro, Ark.; complaint issued May 3, 1939; order issued May 12, 1943. Order directed respondents to discontinue the following misrepresentations and false advertising claims, among others, for this product, formerly known as "Nash's C & L Tonic": That it will cure malaria, biliousness, constipation, chills, fever and ague; that it is an effective tonic which will restore vigor and vitality; that it both prevents and cures colds, is a new discovery which is in no way habit forming, that it is endorsed by nurses, physicians, school teachers and health officials throughout the southern part of the United States, and that nine out of ten persons living in that region have malaria. The order recognized that the product, as now constituted, is an antimalarial preparation and laxative, but when taken according to directions on the label, is not an effective treatment for the cure of malaria or a cure or remedy for liver trouble, dyspepsia or the other ailments enumerated, and will not restore vigor or vitality or prevent or cure colds, nor is it endorsed by nurses, physicians or health officials throughout the south. A previous order from the Commission, issued August 6, 1939, had directed the same Nash persons to cease representing that Nash's C & L Tonic, also then known as Nash Chill and Liver Tonic, would cure malaria and some other results.

Nature Seed.—Beatrice Kornstein, trading as Nature Seed Company, New York; complaint issued March 12, 1943; order issued Sept. 29, 1943. Order directed promoter to discontinue the following advertising misrepresentations: That the product is a doctor's prescription for delayed, unnatural or suppressed menstruation; that it constitutes a competent treatment for such conditions; that it is composed of ingredients derived from nature and is harmless to use. Miss Kornstein further was ordered to discontinue any advertisement which failed to reveal that the use of Nature Seed might cause gastrointestinal disturbances and in cases of pregnancy might result in uterine infection and blood poisoning.

Todd's Capsules.—J. E. Todd, Inc., Kenmore, N. Y.; complaint issued August 16, 1941; order issued July 30, 1943. Order directed the respondent to discontinue any advertisement which represented that the product has any value in treating arthritis, neuritis, rheumatism or similar diseases or conditions. The order further directed respondent to cease representing that his preparation will alleviate the symptoms of pain associated with such diseases or conditions, or that it possesses any curative properties in treating these disorders. The Commission found that the value of the product, if used in adequate amounts, is limited to neutralizing the acids of the stomach contents and to acting as a mild laxative.

World's Tonic.—William J. Cooksey, also known as Ross Dyar, trading as World's Medicine Company and using postoffice boxes in Columbus, Ohio, and Indianapolis; complaint issued Oct. 19, 1942; order issued Oct. 30, 1943. Order directed respondent to cease representing that his product is a cure or remedy for anemia, swollen joints, kidney disorders, headaches, or the numerous other ailments and diseases enumerated in the advertising, or that it possesses any value other than that of a laxative and a bitter; and to discontinue any advertisement which did not reveal that the product should not be used when nausea or other symptoms of appendicitis are present; provided, however, that such advertisement need contain only the statement, "Caution: Use only as directed" when a warning to the same effect is included in the label directions. The Commission reported that World's Tonic was a mixture of cascara and other cathartics, with small amounts of gentian root, prickly ash bark, and other substances which, by reason of their bitter taste, tend to give it the properties of an appetizer or "bitter tonic," but that, aside from its action as a laxative and a bitter, it was without therapeutic value.

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

Bevill's Lotion and Bevill's Corn Remedy.—John H. Bevill, trading as I. L. Bevill Company, Birmingham, Ala., has represented that his lotion will cure, heal or relieve athlete's foot in two days, relieve all types of eczema and effectively treat skin diseases resulting from bacteria or parasites; also that his preparation for corns is an effective treatment for bunions or ingrowing nails or will rid one of corns in from 1 to 5 days. In June 1943 he entered into a stipulation with the Federal Trade Commission in which he agreed to discontinue these advertising misrepresentations.

Gly-Cas.—This is a laxative sold by one Medora Whinrey, trading as Gly-Cas Medicine Company, Muncie, Ind. In June 1943 she stipulated with the Federal Trade Commission that she would discontinue any advertisements which failed to reveal that the product should not be used when abdominal pains, nausea or other symptoms of appendicitis are present; provided, however, that it would be sufficient to state in the advertisement, "Caution: Use only as directed" if and when the directions for use on the label contain a warning statement to the same effect. Records show that in May 1941 the Gly-Cas Medicine Company was ordered by the Commission to discontinue certain advertising representations for Gly-Cas. Among these were that it was a cure or remedy for constipation, indigestion, bloating or sour stomach, pains of rheumatism or neuritis, kidney disorders and some other ailments, when such conditions are due to causes other than constipation.

Laxo.—This preparation is sold by Benjamin Zwanger of Brooklyn in connection with his "Laxo Method" of dieting. In July 1943 Zwanger stipulated with the Federal Trade Commission that he would discontinue any advertisements which failed to reveal that Laxo should not be used when abdominal pain, nausea, or other symptoms of appendicitis are present, and that its frequent or continued use may result in dependence on laxatives. The stipulation provided, however, that it would be sufficient for such advertisements to state "Caution: Use only as directed" if the label of the product bears a similar warning.

Correspondence

PROPHYLAXIS OF SPOTTED FEVER

To the Editor:—It is thought that several comments should be made relative to your editorial entitled "Prophylaxis of Spotted Fever," which appeared in *THE JOURNAL*, May 20. By just glancing over the editorial it would seem that the observations of Anigstein, Bader, Young and Neubauer might have a clinical application as suggested. If one keeps in mind several known facts concerning Rocky Mountain spotted fever and the immunologic principles involved, it becomes evident that its practical application will be difficult if not impossible.

1. In order for active immunity to develop following local infiltration with immune serum around the site of a tick attachment, that tick must not only be infected but actually have passed the rickettsias on to the patient. If these two prerequisites are not satisfied, certainly there will be no subsequent immunity. Since only one among several hundred ticks, at the most, is infected, and even it must feed for several hours before it is able to infect, the chances of satisfying the two requirements mentioned are small. We know these chances are remote, for with the millions of tick bites that undoubtedly occur in the United States each year approximately only 500 cases of Rocky Mountain spotted fever are reported.

2. If a subsequent immunity after the infiltrations with serum is assumed, it will in most instances lead to a false sense of security on the part of both physician and patient. Lacking knowledge of the immunity status of the patient, it then becomes necessary to infiltrate for each separate tick bite. This would be an undesirable procedure if the commercially available immune rabbit serum is used, owing to the probability of an induced hypersensitivity to rabbit protein from repeated infiltrations. It is felt that the specific immune serum should be reserved for the treatment of actual cases of the disease. If human convalescent serum was employed we would still be confronted by the troublesome questions of which tick in several hundred is of real danger, and are we going to infiltrate for every tick bite? There is also the possibility to be considered, if human convalescent serum is employed, of producing hepatitis in some of the persons treated similar to the experience following yellow fever vaccine containing human serum.

3. Finally, it might also be mentioned that a fair number of cases of spotted fever give only a history of tick contact such as removing the arthropods from animals rather than the history of a definite tick bite. These individuals could not have had a prophylactic local injection of serum, and a question arises as to the actual site of infection even when a definite tick bite is present.

There are several methods available for the prevention of Rocky Mountain spotted fever. The first of these is the non-specific precautions that can be taken by any one. They consist of avoiding areas known to be heavily infested with ticks, wearing clothing tight at the wrists and ankles to deny ticks admittance to the body, and finally the prompt and efficient removal of ticks after exposure. It has been shown that an infected tick must feed for a few hours before it will transmit the disease; therefore, if they are removed promptly the chances of becoming infected are greatly reduced. However, even in areas known to be heavily infected the ratio of infected to noninfected ticks is very low. It has been estimated that this ratio in heavily infected areas is not more than 1:300.

The other available method of prevention of this disease is the acquiring of active immunity by vaccination with the specific antigen. Years ago Spencer and Parker showed that a vaccine against this disease could be made by the phenolization of infected tick tissues. Experience with this vaccine over a period

of some fifteen years indicates that the case fatality is definitely reduced and perhaps the morbidity as well. Rocky Mountain spotted fever vaccine is prepared by the United States Public Health Service at its Rocky Mountain Laboratory at Hamilton, Mont., and is dispensed from there to the various state health departments.

More recently Cox has been able to prepare a vaccine from infected yolk sacs of fertile hen's eggs that will immunize laboratory animals. This improvement in method will increase amounts of vaccine available. The Cox type vaccine is now being produced by the Public Health Service as well as by several of the biologic firms and can be purchased through ordinary commercial channels.

Widespread vaccination against a disease as sporadic as Rocky Mountain spotted fever offers but little hope of its control. It would be unwise as a public health measure to recommend vaccinations for other than those unusually exposed to ticks in areas known to be infected. The nonspecific method of prophylaxis should be advised for the rest of the population.

PHLEBOTOMUS (PAPPATACI OR SANDFLY) FEVER

To the Editor:—In the July 1 issue of *THE JOURNAL* the first article on "Phlebotomus (Pappataci or Sandfly) Fever," by Major Albert B. Sabin, Lieut. Col. Cornelius B. Philip and John R. Paul, M.D., immediately commanded my attention as I had had considerable experience with sandflies in China and had identified the phlebotomus in relation to sandfly fever in North China.

In the middle of the second paragraph of this article it is stated that "there are also reports which would suggest that this disease may occur in China as far north as Peiping and Tientsin and as far south as Hongkong. . . ." This question was answered in a paper which I presented at the biennial conference of the China Medical Missionary Association at Shanghai in February 1915 and published in the *China Medical Journal* in March 1915, under the title of "Sandflies (Phlebotomus) in China and Their Relation to Disease: Preliminary Considerations of the Identification and Distribution of Sandflies in China, with Special Reference to Phlebotomus Papatasi, Scopoli." The article was also reprinted in the *Tsing Hua Journal*, volume 1, No. 1, November 1915, pp. 12-19, and translated into Chinese.

At that time it was my privilege to be the physician to Tsing Hua College (United States Indemnity College) near Peking. For six years I had an opportunity to study sandfly fever among the students who came from all parts of China and also among the American and Chinese faculty. Specimens of the flies captured in and near Peking were sent to the Imperial Bureau of Entomology of the British Museum, where they were identified by Mr. Guy A. K. Marshall and later by Professor R. Newstead.

A considerable number of the flies were also sent to Frederick Knab, entomologist of the United States National Museum in Washington, who studied them carefully. Both of these men identified the phlebotomi as a new species, and Newstead gave the name of "chinensis" to this species. Specimens of my flies are still on file in the National Museum in Washington. However, in my paper in the *China Medical Journal* I have given photomicrographs of the species caught near Tsing Hua College, Peking, China.

While at Tsing Hua College I sent a questionnaire to a number of physicians and missionaries on the prevalence of sandflies (*Phlebotomus*) in China. Replies were received from a number of districts, and it was evident that sandflies and sandfly fever were prevalent in Peking, Tientsin, Tongshan and other places along the Tientsin-Shanhaiwan Railroad as well as around Kalgan. In other places in the south very few were reported.

I have much unpublished material relating to the measurements of my specimens and also clinical details on the number of cases of phlebotomus fever that I have had an opportunity to study. I am sorry that I have no extra copies of the reprint of my articles, but these may be found in the Surgeon General's Library in Washington and in the bound volumes of the *China Medical Journal* in the Allen Memorial Medical Library in Cleveland.

RICHARD A. BOLT, M.D., Cleveland.

Director, Cleveland Child Health Association.

FETAL AND NEONATAL MORTALITY COMPLICATED BY DIABETES

To the Editor:—In the article "Fetal and Neonatal Mortality in Pregnancy Complicated by Diabetes" by Miller, Kuder and Hurwitz (*THE JOURNAL*, January 29) the authors conclude that "an increased fetal and neonatal mortality can be observed from fifteen to twenty years before the clinical symptoms and signs of diabetes can be recognized."

This report prompted a review of the subject in 200 diabetic married women attending the metabolism clinic of the Mount Sinai Hospital. The patients were interviewed personally, whereas Miller and his co-authors used record room data.

In the article, a fatality analysis made in five year periods for the twenty years prior to the onset of diabetes revealed a rate of 23.8 per cent with 252 children born and 60 deaths. In our group there were 54 mothers who bore all their children in the twenty year period prior to the onset of diabetes; 141 children were born, 6 were stillborn and 6 died before ten days, constituting a fetal and neonatal mortality of 8.5 per cent compared with 23.8 per cent in their group. Our fetal and neonatal mortality of 8.5 per cent in the twenty year period preceding the onset of diabetes is closer to that obtained in the nondiabetic patients, 5.4 per cent of the Miller series. The figures for our entire group of patients, including births before the twenty year prediabetic period, are 5.7 per cent, with 598 births and but 21 stillbirths and 13 infant deaths within ten days after birth.

We do not find that the "fetal and neonatal mortality is extraordinarily high long before the mothers develop symptoms or signs of diabetes." In our experience the prediabetic period is associated with a fetal and neonatal mortality not significantly greater than in normal patients.

VACATIONS AND THALASSOTHERAPY

To the Editor:—The special article in *THE JOURNAL* April 15 entitled "Thalassotherapy" has come to my attention. It may be that the scientific material presented in this article is valid and correct, but it should be pointed out that any effort to evaluate the value of a vacation in any place must include some consideration of who is having the vacation, with whom he is having it, why he needs it and what he does while he is on it. The authors of this article must be aware of the fact that there are some individuals who live in the region the article is written about and are continually exposed to the air, water and sun you mention, and that in spite of these things these individuals find it necessary to take vacations elsewhere. There are some

individuals for whom a vacation at the seashore is undoubtedly injurious since, through so doing, they are trying to run away from problems and difficulties which are within themselves.

Before the series of articles in this type of therapy is completed, it is suggested that one be secured which gives attention to the total factors operative in this matter.

Hygiene, Queens Hospital.

USE OF CATHARTICS BEFORE GASTRO- INTESTINAL ROENTGENOLOGY

To the Editor:—In response to my communication in *THE JOURNAL* of May 27 regarding x-ray studies of the intestinal tract, I have heard from a number of roentgenologists. Their general plea is: We can't show the intestines if they are full of feces and gas, therefore we must use cathartics and enemas. They challenge me to suggest a better way, which of course I am unable to do.

Mostly they speak of "spastic colon" as a diagnosis too readily made.

All I would ask is that the profession shall understand that, for gastrointestinal studies, enemas and cathartics are prescribed by roentgenologists, and that therefore the films show the bowels, not as they normally are, but as they are under the influence of such measures.

WALTER A. BASTEDO, M.D., New York.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Insanity: Irregular Commitment to State Hospital as Affecting Right to Release of Insane Person.—Barbee, an elderly man afflicted with senile psychosis, lived without restraint with his daughter-in-law, Mrs. Barbee. March 16, 1943 one Woods, a brother of Mrs. Barbee, filed what is referred to as a citizen's affidavit of insanity with respect to Barbee with the probate court of Pulaski County, Arkansas. The next day Woods filed and presented to the probate court judge certain interrogatories and answers of two physicians with respect to Barbee's insanity. One of these affidavits was executed by Dr. Rowland on the basis of an examination he had made of Barbee the preceding day. The other affidavit was executed by Dr. Holmes on the basis of an examination he had made of Barbee in February 1943, when he had administered an antirabies treatment to him. The probate court held a hearing on the matter in Barbee's absence and without any notice whatsoever to him and issued a warrant for commitment, directing the sheriff to take Barbee into custody and to deliver him to the superintendent of the Arkansas State Hospital for Nervous Diseases. Mrs. Barbee and Woods requested the sheriff to hold up execution on the warrant until they had decided whether they could care for Barbee without the necessity of commitment. May 26, 1943, on Mrs. Barbee's and Woods' request, the sheriff took Barbee into custody and delivered him to the hospital. On Barbee's arrival at the hospital a diagnosis was made of "senile psychosis, confused type, plus paranoid trend." Shortly thereafter a petition for a writ of habeas corpus was filed on behalf of Barbee, alleging that he was sane and that the proceedings before the probate court were void because of lack of notice to him, because the judge failed to impanel a jury and because there was no competent evidence tending to establish his insanity. At the hearing on the petition Dr. Murphy, a psychiatrist who had examined the petitioner at the request of his attorney, testified that the petitioner had "senile psychosis," that he probably would not recover sufficiently to take care of himself physically or in the business world and that he would require supervision. Dr. Hollis, a member of the hospital staff, testified as to the findings of the hospital staff and that in his opinion Barbee was insane, in all probability would become worse instead of better, that he would require constant care and supervision and that there would be need to prevent him from wandering off and exposing himself to weather and the hazards of traffic. The petitioner himself appeared at the hearing and testified. From an adverse decree by the trial court, Barbee appealed to the Supreme Court of Arkansas.

After the issuance of the warrant of commitment but before Barbee was actually confined to the hospital, a new act respecting the commitment of the insane became effective in Arkansas (Act No. 241, Acts, 1943). This act, said the Supreme Court, is rather comprehensive and greatly modifies the prior law relating to who, and methods by which, persons may become patients in and be discharged from the State Hospital for Nervous Diseases. Because the proceedings in which Barbee was adjudicated insane were had before the effective date of Act 241, we must look to the then existing law to determine whether he was properly committed. For the purpose of this opinion we assume, without deciding, that the commitment proceedings were not in conformity with the then existing law. However, if evidence indicates that one committed to an institution for the insane is actually insane, and such evidence is here present, the court should not order his discharge, regardless of the invalidity of the proceedings under which he was committed, but should direct his continued restraint until such time as proper proceedings can be had for a formal adjudication of insanity. As authority for this statement the court quoted from *Ex parte Smith*, 167 Ark. 80, 266 S. W. 950. In that case this court sustained the action of the lower court in refusing to direct the

discharge of a patient, admitted insane, from the U. S. Veterans Hospital, who had been placed therein by his guardian without the formal order of any court. The court there said:

Under those circumstances, the petitioner is not entitled to an absolute discharge from the custody of the hospital authorities. According to the allegations of the response, which must be taken as true, the hospital authorities rightfully received petitioner into their custody, and the court should not require them to turn him loose and permit him to go at large, if he is afflicted in the manner and to the extent set forth in the response. In this respect the hospital authorities are in the same attitude and are charged with the same duties as any other person having rightful custody of an insane person. The duty is not to abandon an insane person until he can be taken into custody by such person or institution as is charged by law with the duty to care for the insane. The statutes of this state provide that, when a person is insane so as to endanger his own person, or the person or property of others—"it shall be the duty of his guardian, or other person under whose care he may be, and who is bound to provide for his support, to confine him in some suitable place until the next term of the probate court for his county, which shall make such order for the restraint, support and safe-keeping of such person as the circumstances of the case shall require." Crawford & Moscos' Dig. sec. 5854. Adequate provision is made by law for the custody and care of insane persons, and of course these statutes have full application to an insane person in the United States Veterans' Hospital, but, until some steps are taken for the legal care and custody of such insane person, the court will not require the absolute discharge of the patient from custody.

Under certain conditions specified in Act 241 of 1943, the court continued, the superintendent of the state hospital may admit persons to the hospital as patients without the order of a court. Under that act he may discharge any person from the hospital who in his opinion is then mentally competent, whether such person was admitted with or without an order of court. Of course, the superintendent would have no authority indefinitely to hold in involuntary custody any person who had not been committed by the proper order of a court of competent jurisdiction. Recognizing that patients admitted without a formal commitment, or through irregular process, might later demand their discharge at a time when their condition was such as to require their continued confinement, the lawmakers, by section 6 of the 1943 act, specifically authorized the superintendent to apply to and obtain from the probate court of the county of any such patient's residence a writ of commitment. If the petitioner's present mental condition is such that his discharge would not be dangerous for either himself or society, and if his mental condition is such that his own best interest does not require that he remain in the hospital for further treatment and supervision, then he should be discharged, but if his condition is to the contrary he should continue as a patient in such institution. If the superintendent of the hospital is of the opinion that the petitioner should be discharged, he is clothed with ample authority to effect his release. On the other hand, if he entertains a contrary conviction, he may and should apply to the probate court of the proper county for the issuance of a writ of commitment in accordance with the act.

The court accordingly modified the decree so as to provide that the petitioner's petition will be dismissed without prejudice to his right again to assert all matters alleged therein if the superintendent shall fail to apply within thirty days to the proper probate court for a writ of commitment.—*Barbee v. Kolb*, 179 S. W. (2d) 701 (Ark., 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Myocarditis in Children. O. Saphir, S. A. Wile and I. M. Reingold.
—p. 284.

Dental Caries and Diet.—In the course of observations by Boyd, a sharp break was made in the dietetic regimen, the original high fat diets being replaced by diets which offered only half as much fat and twice the amount of carbohydrates. The observations involve dental courses of 59 girls and 52 boys who were examined recurrently for not less than three years each during a routine management of diabetes. Analyzing the data from the standpoint of the relative protection against caries afforded by the higher versus the lower fat diets, the author noted that such differences as exist bear no constant relationship to the level of fat in the diet. The differences between the values for the groups who received exclusively the higher and the lower fat diets are equivocal. No constant or significant difference in the average rates of progression of caries was found between two groups of children whose fat ingestion differed by 100 per cent. Protection against caries is thought to depend on the common high nutritive worth of the contrasted diets.

Diseases of Liver and Biliary Tract: Hepatic Involvement in Various Diseases Related to War. C. H. Greene.—p. 349.

Dermatomyositis.—Jager and Grossman report clinical and laboratory observations and muscle biopsies in 9 cases of dermatomyositis observed in Vanderbilt Hospital. Evidence of involvement of muscles was present in every instance. Frequently there were tenderness, weakness and atrophy of skeletal muscles. Occasionally the so-called vital striated muscles of deglutition and respiration were affected. In all instances biopsy specimens of skeletal muscles revealed certain histologic changes. These microscopic lesions are not specific for this disorder. Similar muscular changes have been observed in rheumatoid arthritis, pneumonia, thyrotoxicosis and other diseases. Involvement of the skin occurred in 7 of the 9 cases. In 2 the mucous membranes of the mouth were affected. In 1 case there was a diffuse scleroderma, and in 2 others sclerodermatous changes were confined to the hands. A history of Raynaud phenomena was elicited in 4 cases. Extensive laboratory studies revealed no constant abnormality other than spontaneous creatinuria. Carbohydrate metabolism, as indicated by several types of tests, was apparently normal. Studies of the reaction to overcooling, as shown by the cutaneous temperature, gave results typical of Raynaud's syndrome in the 4 cases with a history of this disturbance and in 1 case without such a history. The variability of the manifestations was sufficient to arouse doubt as to whether "dermatomyositis" is a single clinical entity. A similar view is obtained from reading previous reports of this disorder. It may be necessary to follow the course of the illness for a prolonged period before the diagnosis can be established with certainty.

Diagnosis and Location of Myocardial Infarct by Electrocardiogram.—Baer and Frankel report that electrocardiograms taken in 321 cases revealed infarction in 94 per cent. On electrocardiographic study alone, 52 per cent of the infarcts were found to be anterior and 34 per cent posterior. Of 74 patients coming to necropsy, 70 per cent had anterior, 23 per cent posterior and 7 per cent anteroposterior infarction. Anterior myocardial infarctions are more frequent and more serious than posterior infarctions. Infarction of the anterior wall of the left ventricle is more apt to be missed by electrocardiograms than posterior involvement. Electrocardiographic diagnosis and location of the infarction are highly accurate.

Palindromic Rheumatism.—Hench and Rosenberg describe an unusual, oft recurring disease of joints and adjacent tissues, 34 cases of which have been studied in the arthritis service of the Mayo Clinic since 1928. Its main features are multiple afebrile attacks of acute arthritis and periarthritis, and sometimes of para-arthritis, with pain, swelling, redness and disability generally of only one, but sometimes of more than one, small or large joint, in an adult of either sex. The attacks appear suddenly and develop rapidly. They generally last only a few hours or days and then disappear completely, but they recur repeatedly at short or long, irregularly spaced intervals. Among the various predisposing factors mentioned by the patients were seasonal and weather influences, menstrual factors, work fatigue, trauma, infection and food sensitivity. Their investigations on the etiology included studies on a possible allergic nature, on an infectious origin and on an angioneurotic

factor. The attacks presented no apparent relationship to acute exogenous infection such as sore throat or influenza, and most of the patients had long since been relieved of infected foci with only temporary or no relief. Angioncrosis was probably not the cause of the articular and other reactions of the palindromic rheumatism. Since the most characteristic feature is the frequent recurrence of the attacks, the authors decided on the term "palindromic," meaning recurring. Numerous treatments had been used by the patients, generally without success. Most of them had fallen back on the use of heat and analgesics during attacks. The remedies tried by the authors were predicated on the idea that the disease might be allergic; later, measures to combat some possible infection were instituted. Neither plan of attack has produced notable results. There appears to be little or no tendency for attacks to become chronic. Despite the thousands of attacks suffered, not a single joint has been crippled permanently.

*Intra-Abdominal Apoplexy. A. I. Haugen.—p. 198.
Encephalitis Complicating Measles. W. Cary.—p. 201.

Intra-Abdominal Apoplexy.—Haugen analyzes the 25 recorded cases of intra-abdominal apoplexy with regard to etiology, clinical picture, diagnosis and treatment. He stresses the importance of early recognition of hemorrhage as the cause of the patient's collapse, and on the necessity of prompt and adequate replacement therapy with blood and plasma during and after attempts to secure surgical hemostasis. The preoperative diagnosis can be only tentative in those who have an essentially unruptured hematoma, but on finding such a condition at operation one can usually find the bleeding point. In only 6 of the 20 patients operated on did such circumstances prevail that the

surgeon could deal directly with the bleeding vessel, usually by ligation. Five of these 6 patients recovered. On the other hand, those who after one or more episodes of bleeding have developed a massive hemoperitoneum present a picture making a surgeon hesitate to add the risk of operation to their already desperate condition. In 13 such patients operated on the bleeding point could not be found to permit surgical hemostasis; but 8 of these recovered. The immediate indication in these cases is to reestablish an effective circulating blood volume, first to the point of operability by means of intravenous serum or plasma and then, after opening the abdomen, to salvage the large quantity of blood found there and after careful filtration to reinfuse it into the patient's veins. It seems important to keep the patient as comfortable and quiet as possible and to avoid catharsis, enemas, food, rough palpation and other factors that might tend to cause more bleeding. A case is reported which was mistakenly diagnosed as appendicitis while in the simple hematoma stage. After a relatively silent interval of four days there developed recurrent episodes of collapse due to free intraperitoneal bleeding, which proved fatal on the fifth day. Necropsy disclosed a peritoneal cavity full of clotted and liquid blood. The hematoma extended up around the pancreas. The original point of bleeding could not be identified. As in so many of the other recorded cases, it is doubtful that the bleeding point could have been found at operation at any time after the original rupture of the hematoma.

Parachute Jump from 32,000 Feet Without Oxygen.—Kirschbaum reports that a man whose plane caught fire while he was traveling at 32,000 feet jumped from the moving plane at that height. His oxygen tube was torn during the jump. He held his breath as he tumbled. At 30,000 feet he realized that he might become unconscious and therefore pulled the chute cord. He was unable to hold his breath any longer. When the chute opened there was a violent jerk in the right groin due to the crotch straps. His clothing consisted of an ordinary cloth flying suit and leather jacket, and he wore no gloves. After the chute opened, he placed his hands in his armpits. He lost consciousness at about 30,000 feet and regained it again at about 10,000 feet. He attempted to pull himself up on the ropes of the chute, but he was unable to do so because of weakness of his hands. At 3,000 feet he was very clear, and he made an effort to guide the chute so that it would not fall over him. Weakness of the hands still persisted. The entire descent took twenty-one minutes. He landed on both feet, and the chute fell to the right. He had sufficient presence of mind to advise the farmer who found him not to carry him without a litter. Physical examination revealed a hematoma above Poupart's ligament. There was slight tenderness on pressure in the region of the upper lumbar spine. X-ray examination revealed dislocation of the first lumbar vertebra and disarticulation of the rib at the twelfth thoracic vertebra. Hyperextension treatment on the Bradford frame was advised. He was placed in a plaster jacket in extension after reduction of the lumbar dislocation under gas-ether anesthesia six days after the parachute jump. Two months after the accident he was walking about in a plaster body cast and his general condition was excellent.

Dermatome Hypalgnesia with Herniation of Lumbar Intervertebral Disk.—Keegan emphasizes that herniated lumbar intervertebral disks commonly compress single nerve roots and present associated dermatome hypalgnesia in the lower extremity, which is accurately diagnostic of the location of the lesion. He presents a new dermatome chart of the lower extremity based on hypalgnesia from proved single nerve root loss. These findings are in disagreement with the common dictum that loss of a single nerve root produces no loss of sensation. The nerve root most commonly compressed by herniated intervertebral disk is the first sacral nerve root. Recognition of the syndrome of lesions of the first sacral nerve root, with its characteristic dermatome hypalgnesia and loss of the ankle jerk, removes suspicion of extraspinal lumbar pathologic change as a possible cause, as this nerve root is entirely intraspinal until its exit through the first sacral foramen. Subjective and objective numbness and reflex loss are organic neurologic signs not explainable from possible reflex reference from obscure distant pathologic changes. Numbness over the distribution of a single nerve root dermatome necessitates a lesion involving that root. The common occurrence of pathologic changes in the fifth and fourth lumbar disks, leading to later herniation, should be considered more often as a possible explanation of early attacks of low back pain. Manipulative treatment should be directed to reduction of this beginning herniation. Roentgenograms of the lumbar spine should be directed to the disk indicated by the unilateral single dermatome hypalgnesia. A conservative attitude should be maintained in surgery of the herniated disk, for in many early cases improvement occurs without surgical intervention; however, with or without operation these patients present some permanent disability which requires back protection. A spine fusion operation is not often indicated because of the unreliability of preoperative selection of cases and the imperfect results of this time consuming procedure. Deliberate section of a nerve root sometimes is warranted and effective to relieve persisting single nerve root pain after an operation for a herniated disk. The nerve is identified by its dermatome hypalgnesia. The author performed section of the nerve root in 9 cases.

Use of Penicillin in Navy.—Barr summarizes the 1,976 cases treated with penicillin and reported to the Bureau of Medicine and Surgery prior to Jan. 1, 1944. No serious untoward effects attributable to penicillin were noted. Penicillin is administered either continuously by the intravenous route or intramuscularly every three hours night and day. The average recommended daily dose is 60,000 units if the intravenous route is used, and 120,000 units if the intramuscular route is elected. For critically ill patients combined intravenous and intramuscular penicillin therapy for the first twenty-four hours may be necessary, a maximum of 240,000 units

being given by each route during that interval. In mixed infections better results may be obtained by using penicillin and sulfonamide therapy concurrently than would be the case if either was used alone. Frequently repeated blood transfusions appear to be of value in reinforcing the patient's hemopoietic system. Topical application in soft tissue wounds and in osteomyelitis appears to be of therapeutic value. It may be applied in saline compresses containing 250 units per cubic centimeter of solution. The solution should be trapped at the site of the lesion and should be renewed every six to eight hours. Simple irrigation is not effective. Sulfonamide resistant gonorrhea responds dramatically to penicillin therapy; 99 per cent of 1,750 cases were cured by the treatment. Diseases due to *Streptococcus haemolyticus*, *Staphylococcus aureus*, *Clostridium welchii*, *pneumococcus*, *meningococcus*, and certain other organisms are also favorably affected, although the results are not so striking as in gonorrhea. Fifty per cent of the cases of osteomyelitis appear to have been cured by a combination of penicillin therapy and surgery. Long standing chronic cases in which there is bone sclerosis with deep seated walled off pockets of infection appear to be less amenable to treatment than acute cases. Adequate, well planned surgery is still necessary in osteomyelitis.

March Fracture of Femur.—According to Branch, march fracture is most common in the second and third metatarsals, owing to the foot going into pronation under fatigue and then letting the weight come on the plantar and medial sides of the metatarsal heads, tending to twist the shafts of the metatarsals dorsolaterally. The bone affected next in order of frequency is the tibia, usually in the middle third. This fracture occurs most often in infantry recruits. The fibula may be affected in two typical sites: 1. Proximal, a palm's breadth below the head; this lesion occurs usually in gunners and is due to their jumping back and forth from the gun carriage. 2. Distal, just above the external malleolus; this type is commonly found in ice skaters. Fracture of the femur has been considered most common in the lower third. Fracture of the neck of the femur is not uncommon but is often unrecognized. Fractures of the femoral shaft are taught to be due to running in a crouched position or to the strain of marching with full packs. Added factors are the rotary mechanism in the hip joint and the traction that the hip muscles exert. Fractures of the shaft of the humerus occur in hand grenade throwers. The os calcis is fractured usually a finger's breadth beyond the subastragalar joint and is probably due to prolonged marching. The author presents 1 case of march fracture of the femoral shaft and 3 cases of march fracture of the neck of the femur, all of which have been treated at the Harmon General Hospital in the last seven months. Soldiers complaining of symptoms simulating muscle strain, bursitis and the like should have roentgenograms taken to rule out this type of fracture. Insufficiency or exhaustion fracture is probably a better term than march fracture.

Diethylstilbestrol for Oophorectomized Women.—Heller and his associates investigated the effect of relatively small and relatively large oral doses of diethylstilbestrol on menopausal symptoms, vaginal smears and urinary gonadotropins in 23 women who had been subjected to bilateral oophorectomy and followed postoperatively until the menopausal syndrome

had been firmly established. Daily doses of 0.5 mg. by mouth alleviated menopausal symptoms in 20 cases and had an estrogenic effect on the vaginal mucosa in all 23 cases but did not suppress gonadotropic excretion. The average titer of gonadotropins during the administration of this dosage was slightly higher than before treatment, because of increased output of the luteinizing fraction (interstitial cell stimulating hormone). The symptomatic and physiologic effects of the 0.5 mg. dose of diethylstilbestrol were not mediated through the anterior pituitary gland. Daily doses of 5 mg. of diethylstilbestrol administered for one month or longer in 8 cases caused complete suppression of gonadotropic output. Discussing the relationship between the pituitary and the ovary, the author stresses the following points: 1. Gonadotropic hormone is utilized by normal ovaries but not by castrates or ovaries with impaired function, as a consequence of which much larger amounts are available for excretion. 2. Estrogens administered in small amounts increase the output of the luteinizing hormones. It is probable that peaks of estrogen production by the normal ovary have a similar effect. 3. The fluctuations in gonadotropin excretion during the normal menstrual cycle may be due either to variations in the amount of luteinizing hormone produced or to variations in the amount of gonadotropin utilized by the ovaries. 4. Large doses of estrogens administered to castrates have the opposite effect from small doses, suppressing or completely inhibiting gonadotropic output. The suppression by large doses may represent an exhaustion of secretory granules of the pituitary cells. It is possible that long continued smaller doses may have a like effect. Administered estrogens may have similar effects in normal females.

Intradermal Test for Vitamin C Subnutrition.—Slobody made studies on animals and human subjects with various concentrations of a test solution. He shows that raising a 4 mm. wheal with 300th normal dichlorophenol indophenol solution will indicate vitamin C subnutrition states. Of 59 patients with blood vitamin C levels below 0.3 mg. the skin test times were more than 14 minutes in 54. In 10 children on vitamin C deprivation diets the blood levels fell and the skin test times became prolonged. The skin test times were then reduced to normal following administration of ascorbic acid. A skin test time of more than 14 minutes suggests definite body unsatura-

tion, from 9 to 13 minutes mild unsaturation and less than 9 minutes a normal amount of vitamin C in the body tissues. Different tests give information on various aspects of the vitamin C nutritional state and thus will not always correlate. The blood level reflects only recent dietary intake. The skin test parallels the degree of body saturation. Gross and biomicroscopic changes in the gums demonstrate actual tissue changes.

Patent Ductus Arteriosus.—According to Shapiro it is no longer sufficient to make a broad diagnosis of congenital heart disease, since with the present diagnostic aids it is generally possible to identify the lesion more exactly. This is particularly true of simple uncomplicated patency of the ductus arteriosus. Two types of patency of the ductus occur. Failure of closure may accompany a developmental defect of the heart and the open ductus may be the only possible escape for the abnormal circulation. In such instances the flow of blood usually continues as in the fetal circulation; that is, blood flows from the pulmonary artery to the aorta, thereby resulting in cyanosis. The other type of patency occurs as a simple failure of closure and is accompanied by no other cardiac abnormalities. It is this type of case which lends itself to surgical ligation. The author lists the following diagnostic criteria of patent ductus arteriosus: (1) history of heart disease from birth or early childhood; (2) no cyanosis or clubbing of the fingers; (3) stunting of growth in a small percentage of cases; (4) probable thrill over the pulmonic area; (5) characteristic machinery murmur; (6) increased pulse pressure; (7) enlargement of pulmonary artery and branches; (8) normal electrocardiograph; (9) probable enlarged heart. The great majority of patients with patent ductus arteriosus develop some cardiac difficulty in early adulthood. It is quite rare to examine a patient with patent ductus arteriosus over the age of 40. When the diagnosis of uncomplicated patent ductus can be made, surgery should be seriously considered, particularly in patients showing evidence of cardiac strain. In Minneapolis 19 patients with patent ductus arteriosus have been referred for surgical treatment. These patients ranged in age from 3 to 19 years. The ligation has been successfully carried out in 16 instances. Two patients died of hemorrhage. One child developed a blood stream infection about two months after operation, from which she subsequently died. The clinical results in the successful cases have been satisfying.

Preventing Rheumatic Recrudescence.—In the past, efforts to prevent recrudescences consisted in emphasizing certain generally hygienic fundamentals. A well balanced diet high in vitamins B and C, a warm, sunny climate where protection from dampness and chilling is possible, and the avoidance of respiratory infections have been stressed. Because such methods have been inadequate, investigators have adopted immunologic and chemotherapeutic measures. Pennoyer and Hansen utilized prophylactic sulfonamide therapy in the Pediatric Cardiac Clinic of the University of Minnesota Hospital with results similar to those of other workers over a period of from 1938 to 1943. Analysis of cases in which recurrences developed in spite of the sulfonamide therapy revealed that in most cases the drug was being taken irregularly or inadequately, or it had been temporarily discontinued by the patient. Although sulfonamide prophylaxis is not free from danger and requires close medical

supervision, it may reasonably be expected to prevent many rheumatic recurrences and materially affect the mortality associated with this disease. It consists in the prevention or attenuation of streptococcal infections by the continued maintenance of a low blood level of a sulfonamide. Alternative methods of prophylaxis such as immunization against streptococci and control of streptococcal infections with salicylates are available for patients who do not tolerate the sulfonamides.

*Exophthalmos Secondary to Edema and Degenerative Changes in Orbital Tissues. M. H. Soley, with assistance of Jean Hitch —p. 865.

Exophthalmos Secondary to Edema and Degenerative Changes in Orbital Tissues.—Soley discusses the extreme degree of exophthalmos for which Naffziger recommended orbital decompression. At the thyroid clinic of the University of California a considerable number of patients have been encountered in whom exophthalmos has been a presenting feature, and yet the majority of these patients have had about the same degree of hyperthyroidism, the same size thyroids and the same levels of oxygen consumption as the average run of patients with thyrotoxicosis in whom exophthalmos was not prominent. The author reviews the history of 37 patients with severe exophthalmos. The symptoms of exophthalmos were "pop-eyes," excessive watering, photophobia, blurring of vision, either persistent diplopia or diplopia with eye fatigue, swelling about the eyes, conjunctival injection, scratchy lids, frontal headaches and pain on pressure against the eyeballs. The signs were exophthalmos, periorbital and scleral edema, injection of the scleras, widened palpebral fissures, lid lag, frequent winking

(probably due to drying and irritation of the globe), impaired convergence often more pronounced in one eye, and in the worst cases engorged retinal veins, papilledema and corneal ulceration. Twenty-five of these patients had thyrotoxicosis at the time their exophthalmos was a presenting complaint. Their basal metabolic rate, the size of their thyroid, their age and other factors did not differ materially from routine thyrotoxic patients. Special interest in the problem of exophthalmos probably accounts for the rather large number of patients who presented severe ocular symptoms early in the course of their disease before they were treated. The author believes it is important to segregate such patients and to consider the condition of their eyes with special care. If the patient has hyperthyroidism when first seen, x-ray therapy to the thyroid is preferred to subtotal thyroidectomy in order to allow a more gradual return to a healthy thyroid status and to avoid the complication of myxedema. However, if the goiter is large or nodular, operative treatment is still indicated and the patient should be reexamined frequently afterward. Indications for orbital decompression are changes in function of extraocular muscles (paresis or complete loss of function), impairment of vision, corneal ulceration or pronounced edema of the conjunctivas or scleras. Because progression of exophthalmos occurs in nearly half of all thyrotoxic patients who have subtotal thyroidectomy for hyperthyroidism, patients in this category should be watched most carefully following thyroidectomy.

Use of Engineer Stream Crossing Equipment to Transport Litter Patients. A. B. Ranney.—p. 303.

Treatment of Traumatic Peritonitis.—According to Hejduk, internal bleeding and shock are the commonest causes of death in abdominal injuries during the first twenty-four hours. Peritonitis is a later danger and follows a rupture of a hollow viscus or infection of the effused blood. The purulent contents of the abdominal cavity are removed either by dry wiping or by irrigation. Opinions about the effectiveness of these methods are divided. Hejduk worked for nine years

under a chief surgeon who was a partisan of radical irrigation and for seven years at a university clinic where only the drying method was employed. The drying of the abdominal cavity is simple, quick and efficient. Some employ this procedure in all cases of peritonitis, even in traumatic ones. The advantage of the drying method is that the infective material is not diluted and spread all over the peritoneum. Therefore even some partisans of irrigation prefer to perform drying in the early stages. In war surgery it has the advantage that it does not require special equipment and is therefore practicable even under primitive circumstances. The author thinks that in serious progressive cases of peritonitis or in cases with highly virulent infection, irrigation gives better results than the drying method. Also the intra-abdominal postoperative abscesses and fibrous intraperitoneal adhesions are less common after irrigation. He is convinced that lavage under pressure, provided it is done with from 30 to 50 liters of saline solution, as employed by Bakeš of Czechoslovakia, is the best method to remove quickly and gently liquid blood, blood clots, detached particles of viscera, gastric or intestinal contents, urine, particles of missiles or clothing found within the peritoneal cavity. Perforations of the intestine can easily be discovered during irrigation when the irrigating fluid becomes turbid. It is hoped that the average mortality of 8 per cent achieved by Bakeš with irrigation under pressure will in the future be lowered even more by the combined use of lavage and the administration of sulfonamide compounds or penicillin.

Hemolytic Transfusion Reaction Due to Rh Factor.—Howell and Hobbs describe a transfusion reaction which occurred in an army officer aged 45 who was given a transfusion following an operation. He had had two previous transfusions, the first in January 1938 with no reaction and the second in March 1938 followed by a severe chill and fever. The possibility that a reaction might occur due to Rh incompatibility was considered, but no anti Rh serum was available. The patient was given 400 cc. of citrated whole blood by the drip method over a period of ninety minutes. Forty-five minutes after the completion of the transfusion he had a severe chill. His temperature rose to 102 F. He developed jaundice, the icterus index rising to 62 units within sixteen hours of completion of the transfusion. In the next twenty-four hours he voided only 90 cc. of urine containing large amounts of urobilinogen. He recovered slowly, over a period of several weeks. Anti Rh serum was obtained, and it was found that the recipient's cells were Rh negative. Rh positive agglutinins were demonstrated in his serum. The donor's cells were Rh positive. The authors stress the necessity of determining the Rh factor in recipients of repeated blood transfusions.

Alloxan Diabetes with Diabetic Complications.—Bailey and his associates describe the occurrence of diabetic cataracts in rabbits made permanently diabetic by the use of alloxan. Bilateral diabetic cataracts developed in four to six weeks in rabbits made diabetic with alloxan. The production of alloxan diabetes in rabbits depends on the dosage. Repeated injections of 20 mg. per kilogram were not sufficient to produce diabetes. Forty milligram doses produced diabetes within two weeks in 2 rabbits, suggesting a cumulative effect of alloxan with the larger dose. Microscopic studies of the pancreas in 2 rabbits immediately after the production of diabetes by the repeated

injection of 40 mg. of alloxan per kilogram revealed that some cells of the islets of Langerhans showed hydropic degeneration, others showed irreversible changes and some were essentially normal, whereas occasional cells were in the process of mitotic division. The pancreatic acini were normal. In rats the subcutaneous administration of 200 mg. of alloxan per kilogram is feasible for producing diabetes. The occurrence of cataracts and of diabetic acidosis and coma in the rat is reported.

Curare as Adjuvant During Inhalation Anesthesia.—According to Smith, curare has been subjected to a thorough pharmacologic study and a product has been obtained which seemed safe for human trial. It is known under the term "Intocostin." Curare has been used in convulsive states, in preventing fractures during metrazol shock and in the treatment of spastic disorders. Cullen in 1940, seeking an aid to anesthesia that would give ideal relaxation, administered curare to dogs. Griffith and Johnson reported its use on 25 patients anesthetized with cyclopropane. Smith administered curare to relieve the muscle spasm in poliomyelitis unanesthetized, and in cases anesthetized with pentothal sodium and with cyclopropane. He administered Intocostin in 1 case of tetanus and in 50 as an adjuvant during inhalation anesthesia. The typical curare action consists of an interruption of nervous impulses at the termination of the nerve fibers at the muscle cells. It probably consists in neutralization of the acetylcholine reaction which constitutes the fundamental neuromuscular stimulation mechanism. Intocostin seems to exert no effect on the heart or peripheral circulation. The maximum effect of curare when given intravenously seems to occur within one to two and a half minutes. Overdose leads to respiratory paralysis, the treatment for which is adequate artificial respiration with oxygen. Neostigmine and physostigmine are specific antidotes. The use of pentothal sodium only as an induction agent does not appreciably increase respiratory depression. Temporary relief of muscular spasm in poliomyelitis has been obtained by the use of curare alone and in combination with both cyclopropane and pentothal anesthesia. Curare appears to be one of the greatest aids introduced into the field of anesthesiology, but its use should not be indiscriminate. It should be administered by those thoroughly familiar with its actions.

Fractures of Facial Bones. B. K. Rank.—p. 184.

*Shattering Gunshot Wound of Elbow. J. Devine.—p. 208.

Deceptive Action of Muscles in Peripheral Nerve Lesions.—Sunderland describes trick or supplementary movements which have been observed in 170 cases of peripheral nerve injuries. These are voluntary movements which can still be effectively carried out even when those muscles customarily held to be responsible for their execution have been deprived of their nerve supply. Trick movements have been recorded in isolated and combined lesions of all the main peripheral nerves. The immediate recognition of such movements in peripheral nerve injuries is of considerable importance, since the failure to detect them will lead to false estimates of the extent of the nerve lesion and the progress of regeneration. This will in turn result in incorrect diagnoses and in unjustified optimism concerning either the progress of spontaneous regeneration or the efficacy of a surgical procedure designed and undertaken to facilitate regeneration.

Shattering Gunshot Wound of Elbow.—Devine reports a case in which the left elbow was a pulpy mass, and the forearm dangled by bridges of soft tissue anterolaterally. Three to 4 inches of the upper ends of the radius and ulna were missing, along with the ulnar nerve. The wound was blackened and soiled. The wound was subjected to débridement, covered with sulfanilamide powder and petrolatum gauze, and the whole limb from shoulder to hand was encased in a plaster. After operation 4 Gm. of sulfanilamide was administered daily for some days. Several days after the operation, pain and swelling of the hand necessitated removal and replacement of the plaster, which was done with the arm at an angle of about 130 degrees of flexion and slight pronation. This angle was chosen because the patient said that in the event of the hoped for ankylosis occurring this position would be the most advantageous position for him in his clerical occupation. The man was returned from Tobruk to Australia, and on the trip home he had the usual low grade infection of his wound and had his plaster renewed once. Six months after he had been wounded he had progressing union between the various fragments and was having active movements. Ten months after wounding he commenced clerical work. Now, eighteen months after his wounding, he performs his everyday tasks such as shaving and dressing without assistance and can hold a matchbox in his left hand. He has continued his clerical work.

*Dimethyl Sulfate Poisoning. O. Merkelbach.—p. 481.

Dimethyl Sulfate Poisoning.—The list of industrial poisons issued by the Swiss Society of Industrial Chemistry in 1935 states that dimethyl sulfate is quickly absorbed and that it injures the renal and vascular system. According to Merkelbach dimethyl sulfate is colorless and insoluble in water. It has a boiling point of 187 C. and is rather volatile. It is an irritating and corrosive toxin and acts particularly on the respiratory organs. The onset of clinical symptoms is preceded by a latent period of several hours. In this respect its action is comparable to that of phosgene. Three types of processes resulting from dimethyl sulfate poisoning have been observed in animal experiments. Continuous chronic intake of small sublethal doses results in a cachectic condition as does phosgene poisoning. Clinically the following changes are differentiated: (1) local necrotizing corrosions, (2) corrosion of the air passages by vapors, (3) toxic impairment of kidneys, liver and focal areas of fatty degeneration in the myocardium. The latent period after exposure has been ascribed to an anesthetizing effect. The author gives a brief history of a man aged 35 who had been exposed to dimethyl sulfate vapors in his place of work. Immediately after exposure he felt irritation of the eyes and flow of tears and shortness of breath. Later dyspnea, cough and nasal secretion appeared. The following morning rales were detected over both lungs, and the pharynx, nose and conjunctivas showed inflammation. Six weeks after the exposure the man still complained of palpitation and dyspnea on exertion. This raised the question of whether the changes in the heart or other changes were responsible. The literature reveals that even fatal dimethyl sulfate intoxications caused only slight toxic lesions in the heart. Dimethyl sulfate may attack the central nervous system. Respiratory paralysis has been known to result from it. In the case under consideration the intoxication may have caused a disturbance in the vasomotor regulation.

Chronic Encephalopathy of Boxers. I. de Gispert Cruz.—p. 270.

Functional Renal Insufficiency in Addison's Disease.—Jimenez Dias's concept that the chief biochemical derangement in Addison's disease is a deficiency in the deamination of amino acids by the kidneys was tested on 3 patients. After six days of salt free diet with administration of 6 Gm. of ammonium chloride in the last two days two twenty-four hour urine specimens were collected and pH , free acidity, organic acids, chloride, sodium and ammonium determined. In 10 normal subjects the use of salt free diet and ammonium chloride was followed by high urinary excretion of chloride and ammonium, little change, if any, in sodium excretion, lowering in pH and increase in free acid radicals in the urine. The acidosis elicited by administration of ammonium chloride was thus compensated for by excretion of acid radicals mainly in combination with ammonium. Sodium ion is retained in the organism preferentially to ammonium. Oppositely, in 3 cases of Addison's disease there occurred little change, if any, in ammonium urinary excretion, whereas sodium and chloride excretion were much increased. This was interpreted as an indication that, because of a deficiency in deamination, ammonium is not available for the excretion of acid radicals and the fixed base sodium takes its place. The increase in sodium urinary excretion was found to parallel the severity of Addison's disease, being pronounced in the severe cases and less so in the milder cases. This metabolic or functional renal insufficiency is not specific of Addison's disease, as shown by the finding of the same phenomenon in 1 case of chronic nephritis and in 2 cases of malignant hypertension.

Book Notices

Pharmacology and Therapeutics. By Maude B. Muse, R.N., A.M., Associate Professor of Nursing Education at Teachers College, Columbia University, New York. Fourth edition. Cloth. Price, \$3. Pp. 633, with 83 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

This book should be as useful as the earlier editions for nurses, provided it is supplemented by adequate lectures and references. The drugs are grouped in an understandable way for the person who must appreciate the actions and uses of drugs without the benefit of detailed studies in physiology, medicine, pathology and other subjects such as the medical student receives. For example, preparations which stimulate the central nervous system are placed in one chapter, those affecting the gastrointestinal tract in another. Obviously there may be some difference of opinion where one or more agents properly belong, but any classification will result in misfits. At the end of each chapter is a list of questions for the nurse to use in evaluating what she has learned. The author's awareness of a nurse's responsibility in drug therapy is evident from the statement that a nurse should have knowledge and skill to enable her "to carry out the doctor's orders effectively, administer drugs efficiently, recognize significant effects on patients and report or record these effects intelligently." The contents of this book should aid many nurses in the pursuit of such objectives, although they will have to place their own interpretations on controversial, doubtful or misleading statements which may be found occasionally. For example, the author asserts that the antiseptics in favor today for hand sterilization are mercury bichloride, a mixture of chlorinated lime and sodium carbonate, and alcohol. Obviously these agents are not so favored as they were a few years ago. Further, no agent now available and found practical can be depended on to "sterilize" the hands. Elsewhere is a statement that the Council on Pharmacy and Chemistry "recommends" surgical solution of mercurochrome for preoperative preparation of the skin. The Council does not "recommend" in the true sense of the word; it examines with a view to determine acceptability, by virtue of compliance with certain rules, for inclusion in New and Nonofficial Remedies. Sometimes statements may be found which "date" the section; thus "penicillin (is) all reserved for military use." The author should avoid unnecessary details. Again, unnecessary emphasis is given to treatments not yet generally recognized; for example, the use of liver extract in the treatment of diabetes. Perhaps competent advice from physicians would remove such sources of complaint. Apart from such faults the book can be used by nurses with some confidence that the material is conservatively presented and, if supplemented by lectures and references, will help them in their studies. The index is complete.

Expectantly Yours: A Book for Expectant Mothers and Prospective Fathers. By Marjorie A. Castallo, A.B., M.D., F.A.C.S., Assistant Professor of Obstetrics, Jefferson Medical College, Philadelphia, and Audrey Walz. Boards. Price, \$1.75. Pp. 110, with 16 illustrations by Helen G. Schad. New York: Macmillan Company, 1943.

This small book was written for the woman who wishes to understand the birth process and the medical care involved in the modern management of pregnancy and labor. It is written in an entertaining manner. It does not attempt to supplant the physician but provides sufficient information so that the patient can follow his instructions intelligently. Simple illustrations amplify the text. It can be read with profit by every mother or mother-to-be.

The Earliest Printed Book on Wine. By Arnald of Villanova, Physician, Surgeon, Botanist, Alchemist & Philosopher [1235?-1311] Now for the First Time Rendered into English and With an Historical Essay by Henry E. Sigerist, M.D. With Facsimile of the Original Edition, 1478. Cloth. Price, \$10. Pp. 41, with portrait. New York: Schuman's, 1943.

Arnald of Villanova was a brilliant physician of the middle ages. He was educated in a Dominican school and wrote in "miserable Latin." He practiced in the school of Montpellier. There have been many previous editions of his writings in German and in other languages. The present text provides a reproduction of the first German edition and an excellent translation into English.

A National Health Service. Presented by the Minister of Health and the Secretary of State for Scotland to Parliament by Command of His Majesty, February 1944. Ministry of Health, Department of Health for Scotland. American edition reproduced photographically from the English edition. Paper. Price, 75 cents. Pp. 85. New York: Macmillan Company; London: His Majesty's Stationery Office, 1944.

This is the so-called medical white paper—a statement by the minister of health of Great Britain, Mr. Willink, on his proposals for a national health service. This has been well described in the London letter in previous issues of THE JOURNAL. British physicians themselves have indicated that the white paper deals a little largely with generalities and somewhat too little with the necessary details on which the proposed service may fall. Essentially the white paper encourages the establishment of districts in which medical service would be rendered by a hospital, a group of physicians practicing as a group, a health center and general practitioners who would be feeders to the practicing units. One finds here a great deal of the jargon of propaganda for social medicine. The system is referred to consistently as "free," whereas of course it is merely provided by a system of taxation whereby the government spends the worker's money for him instead of having him spend it for himself.

Aesculapius in Latin America. By Aristides A. Mott, Ph.D., Secretary-Editor of the Pan American Sanitary Bureau, Washington, D. C. Cloth. Price, \$7. Pp. 639, with illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

The author is at some pains to explain why he speaks of South America as Latin America, but he does not say why he called the book "Aesculapius in Latin America" instead of "Medicine in Latin America." Notwithstanding this somewhat too critical comment, the book is the most useful study of the growth and development of medicine in the Spanish and Portuguese speaking countries of America that has yet been made available. It required great study and immense reading as well as personal observation to assemble this useful book. The work is somewhat too profuse in the mere mention of great lists of names of competent workers; yet it serves at the same time to give a good over-all picture. The chapters on vital statistics, social security and distribution of physicians are to be especially commended. At a time when there is a far greater exchange of medical learning and scholarship between the American nations than ever before, this book will serve as a most useful introduction to our southern neighbors.

The Wounded Get Back. By Albert Q. Maisel. With a foreword by Ross T. McIntire, Rear Admiral, Medical Corps, U. S. N. Cloth. Price, \$2.50. Pp. 230. New York: Harcourt, Brace and Company, 1944.

The exceptional privilege was accorded Mr. Maisel of six months in the South Pacific, traveling on hospital ships and in navy planes, visiting first aid stations and all types of navy hospitals. This experience he reflects fully, and he tells his story with rare narrative ability. Anecdotes and cases collected from officers and men lighten the text. Unfortunately there are no illustrations, whereas in the field discussed illustrations often tell far more to the reader than can be found in page after page of text. The book makes clear much of the recent application of military medicine, including, of course, burns, fractures, shark bites, dysentery, malaria and similar tropical troubles. Mr. Maisel's admiration for what the Navy has accomplished is unbounded, and there is hardly a hint of the inevitable failures that occur even under the best of circumstances.

The Clinical Value of Electrocardiography. By Irving J. Treiger, M.D., Assistant Professor of Medicine, University of Illinois. Foreword by James B. Herrick, M.D. Paper. Pp. 20, with 41 illustrations. Chicago: Presbyterian Hospital, 1944.

This atlas has the advantage of simplicity but the disadvantage of brevity. Its chief virtue, as pointed out in the foreword by Dr. Herrick, is that it places this method of study where it belongs: as a useful adjunct to the clinical examination. It may prove helpful to the student who wants a summary of the clinical application of electrocardiography; an important defect, however, is the lack of an account of precordial leads in general and their clinical application, as other precordial leads than the routine lead. It sometimes establish the only clues to a clinical diagnosis. The booklet is simply and clearly printed, aside from some defects in the reproduction of the illustrations, which are not always adequately inked, for example figure 39A.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

MENOPAUSAL BLEEDING AND ENDOMETRIAL CANCER

To the Editor:—Patients with bleeding near or after the menopause are frequently referred to me. If the bleeding does not obviously come from the cervix in most instances I do a dilation and curettage and follow with about 1,500 milligram hours of radium. Of course if I know that there is a fundal cancer ahead of time, I advise surgery or, if the scrapings are suggestive of cancer at the time, I always get a biopsy and increase the radium, following with surgery. Recently one of my physician friends was rather upset because after I had given some radium to 1 of his patients she stopped bleeding for a while and then restarted. I told him that she would be all right, that this frequently happens and that the bleeding might not stop for six weeks or more. I also assured him that she had no cancer: she had a small, fairly firm, freely movable uterus with nothing suggestive of a cancer. I was not able to obtain a biopsy. He thinks this is a rather dangerous procedure and that I will overlook a cancer frequently this way and probably have overlooked one with this patient. I do not think so and have not got into any trouble previously. Please give me your opinion on this matter.

M.D., Alabama.

ANSWER.—It is presumed that a thorough curettement was performed before the radium was inserted into the uterus to rule out cancer of the endometrium. If this was not done, it should be done without delay or, better still, a hysterectomy should be performed. If, however, the insertion of the radium was preceded by a thorough curettement, and microscopic examination failed to reveal carcinoma, it is safe to wait. Frequently there is one episode of bleeding, sometimes two after the use of radium for castration purposes. Generally such bleeding is in the form of a prolonged menstrual period, but seldom does it last for as long as six weeks. If bleeding should persist this long following radium treatment, it is best to remove the uterus. A carcinoma can be overlooked occasionally in spite of a curettement, and carcinoma can arise after radiation therapy. Better results are obtained by using 1,800 milligram hours rather than 1,500 milligram hours.

EFFECT OF TESTOSTERONE ON ADULT MEN

To the Editor:—Is there any danger in the intramuscular injection of testosterone propionate? One of my colleagues told me that occasionally one gets an inhibition of the male hormone with just the opposite effect desired, namely the patient develops female characteristics. I have never seen this in the literature and wondered if there was any basis for it.

M.D., Mississippi.

ANSWER.—The injection of testosterone propionate frequently depresses the activity of the seminiferous epithelium when given to normal adult men. While this effect is temporary as far as is now known, recovery on cessation of treatment may be slow. This property should be taken into account in any plan for protracted treatment. By feminization it is presumed that gynecostasia is meant. This is an occasional response to testosterone propionate but is not known to be progressive or troublesome. More substantial breast growth has been recorded with large doses of methyltestosterone. Whether the difference between the methyltestosterone and testosterone propionate in this respect is a matter of dosage or of inherent peculiarity of the drugs is not clear. No other response to either agent could be described by the term feminization.

Depression of intrinsic androgen production probably occurs, but any expressions of this are of course masked by the effects of the androgen given. Evidences of normal intrinsic androgen production in any individual, however, create a presumption against the usefulness of any androgen.

PRESERVATION OF SKIN GRAFTS

To the Editor:—Please send me available information on delayed skin grafting; that is, grafting skin after it has been removed from the donor for twenty-four to thirty-six hours. Rembert Boyne, M.D., Selma, Ala.

ANSWER.—Little has been written on the preservation of skin grafts for practical use up to the present time. A comprehensive digest by Davis can be found in Lewis's System of Surgery, volume 5, chapter 8, pp. 62-64. A paper read by Dr. Jerome P. Webster at the recent meeting of the American Surgical Association on "Refrigerated Grafts" will soon be published in the *Annals of Surgery*. This presents a simple technic and brings the subject up to date.

HERNIATION OF STOMACH INTO THORACIC CAVITY

To the Editor:—A woman aged 63 has had postbelic gastric distress of a variable degree throughout most of her life. Four years ago an x-ray examination revealed that she had a herniation of approximately one third of her stomach up through the diaphragm into the thoracic cavity. This from all evidence was on a congenital basis. For the past four years the intractable pain from the postbelic muscular spasm has grown progressively worse in spite of conscientious efforts by correct diet, weight reduction, breathing exercises and upright position to alleviate the symptoms. The pain is so severe that it reflexly affects her heart (as well as some direct pressure) and her blood pressure (which is elevated at all times to an average of 160/100). Thorough examination with the electrocardiograph shows moderate change in the cardiac musculature but nothing serious at present. The pain has become so severe that recent attacks confine her to bed for several days. Advice has been received indirectly that some clinics have employed phrenicotomy in this condition with considerable success, especially in relief of the pain from the muscular spasm. Kindly advise as to specific references on this work as well as current medical opinion pro and con on this procedure for the condition in question.

J. Kendall McEane, M.D., Alameda, Calif.

ANSWER.—Whether the herniation is of congenital origin or acquired makes little difference perhaps from a practical standpoint. The fact that nonsurgical measures have proved unsuccessful, that the patient's condition has grown progressively worse and that there is no valid contraindication to operation from the standpoint of the general condition would apparently justify surgical intervention.

There is, of course, a difference of opinion regarding the indications for and against phrenicotomy in the treatment of this condition. Surgeons with a large experience in this field do not advocate phrenicotomy when radical repair can be effected. Temporary interruption of the phrenic nerve by crushing is of value as a procedure preliminary to radical operative repair, especially in the surgical treatment of partial thoracic stomach resulting from congenital short esophagus. In cases in which reestablishment of function of the diaphragm is not desirable because of the danger of recurrence of the hernia, the paralysis can be made permanent by cutting or avulsing the phrenic nerve. Such procedure preliminary to radical surgery is also often of value in the treatment of incarcerated and strangulated hernias because it prevents spasm of muscle and causes relaxation of the hernia ring.

Phrenicotomy as the only procedure does not completely relieve the symptoms. However, with proper dietetic supervision such patients may get along fairly well. This procedure is not applicable to hernias in which a large portion of the stomach is in the thorax, causing pressure on the heart and lungs, nor is it applicable in any case in which the intestine is involved in the hernia. Should the patient refuse to submit to a major operation, temporary interruption of the phrenic nerve might be recommended in the hope that such a procedure would control the painful manifestations at least.

ANESTHESIA FOR CESAREAN SECTION IN WOMAN WITH MYOCARDITIS AND RENAL DISORDER

To the Editor:—What is the proper anesthesia to be used in cases of cardiorenal conditions? Several months ago I was asked to administer an anesthetic for cesarean section. The patient suffered from pronounced myocarditis and renal condition. Respiration was poor and the patient was rather cyanotic. The heart action was weak and irregular. The attending surgeon suggested local or spinal anesthesia. However, after discussion we decided on general anesthesia. Ethylene with a high percentage of oxygen and a small amount of ether was given. The operation was performed without mishap. The patient's condition was improved at the finish of the operation. Respiration and pulse were better. Oxygen was administered at the bedside. The patient and baby are doing well. I wish to know if the course pursued in this case was correct.

Bernard Ploeh, M.D., St. Louis.

ANSWER.—Choice of the anesthetic agent and method involves factors other than the patient's condition. One of the most important of these factors is the skill and judgment of the available anesthetist. Judging from the description of the case and the successful outcome of the operation for mother and child, the choice of anesthetic agent, the method of administration of it and the ability of the anesthetist were satisfactory.

Patients with cardiorenal disease should not be subjected to anoxia. While they tolerate small amounts of ether well, they may not tolerate large amounts of it. Ethylene is an excellent anesthetic agent for patients who are in poor condition if it is administered with a high percentage of oxygen. Spinal anesthesia was no doubt contraindicated in this case, although the patient might well have been operated on after infiltration of the line of incision with a local anesthetic agent. Using local anesthesia, the newborn child seldom needs as much attention or resuscitation as he does when cesarean section is done under

general anesthesia. The immediate postanesthetic administration of oxygen was good prophylaxis. Certain other anesthetic agents or methods, such as intravenous anesthesia and chloroform by inhalation, obviously are contraindicated in a case like this.

PROBLEMS OF MALE MATURATION AND ANDROGEN ADMINISTRATION

To the Editor:—Two youths aged 19 and 21 have recently requested information on the advisability of taking male sex hormone. The younger of the two is normal in every way, but his voice at times changes from its normal baritone to that of a preadolescent boy. In an attempt to keep his voice from changing he apparently strains his voice in talking to the point that he often loses it entirely. Repeated examination of his throat has failed to reveal any pathologic condition. His physique, distribution of body hair and mentality are all normal for a person of his age. The older boy has almost no beard, talks girlishly, tires quickly on attempting normal male sports, and acts, in his own words, "like a sissy." Except for the absence of a beard he appears physically normal in every way. Both these young men have a normal attitude toward their own and the opposite sex. There are apparently no homosexual traits in either of them. Since they are both entering medical school early in the coming year they are anxious to do something as soon as possible to get these "abnormal" conditions corrected. Would testosterone help these young men, and if it did would its effects continue after medication was stopped? If indicated, what size dose should be given and how often? Any suggestions about the handling of these cases would be appreciated.

M.D., Virginia.

ANSWER.—There is no information as to the effect of androgens in further deepening or stabilizing the voices of men with normal sex function. While it is possible that some larynxes require a concentration of androgens higher than that provided by normal intrinsic androgens to effect puberal changes, such a phenomenon is as yet undescribed. The fact that a baritone voice is present at times in this subject suggests that the full puberal impulse has been given to the larynx and that more help might come from voice training than from androgen therapy. If such training is ineffective, however, and the matter is of serious importance, testosterone propionate could be given for a period of two to three months. In this event the sperm content of the semen should be followed. The writer would hesitate to see any profound depression of spermatogenesis protracted over any period longer than two to three weeks, although he recognizes that others might well take such an influence less seriously in view of the recovery of spermatogenesis normally made on cessation of androgen administration. Any effect on the voice would in all likelihood be sustained to a large extent after treatment was stopped. The difficulty is more likely to lie in getting any effect.

The second boy similarly presents a difficult problem. Maturation of beard hair is usually slow in some normal men and may never exceed scanty amounts. Beard hair in the hypogonadal male responds slowly to testosterone propionate and other androgens, and even after months of treatment the yield may be surprisingly meager. Assuming that the testes are normal in the patient in question and are forming spermatozoa properly, protracted treatment with testosterone with its depressing action on the testes should not be risked to secure greater beard growth. "Girlish behavior," even when associated with latent or overt homosexuality, is not readily influenced by the androgens. If the matter is serious, psychiatric care should be sought. Physical inefficiency in this boy might better be dealt with by systematic physical training than by androgens. If reexamination leads to any evidence for mild or partial testicular insufficiency better than that already described the answer would be modified accordingly.

SULFONAMIDES AND HEPATIC DAMAGE

To the Editor:—I have been recently called on to treat a patient for acute cholecystitis with obstructive jaundice of one month's duration due to choledocholithiasis. The patient was unsuitable for operation because of poor cardiac function. At present she has fever ranging from 103 to 104 F. There was sharp disagreement about the use of sulfonamides in such a case, some feeling that they might be too hepatotoxic. What is the present status of this problem?

M.D., New York.

ANSWER.—It is now generally agreed that the sulfonamides on rare occasions may provoke clinical evidence of hepatic damage. This refers particularly to the occurrence of a toxic hepatitis with jaundice. However, when careful liver function studies have been employed in studying this problem it has been revealed that liver dysfunction was not uncommonly induced by sulfonamide therapy. Watson and Spink in a study of 110 patients receiving sulfanilamide observed that the usual therapeutic doses of sulfanilamide were often associated with some evidence of dysfunction of the liver such as urobilinogenuria, elevation of the serum bilirubin or outspoken jaundice. In fact, 16 patients were observed to have jaundice as a result of ther-

apy with sulfanilamide. This incidence is higher than usually recorded and may be due to the individual cases selected for treatment. It is of some interest that a lower incidence of jaundice was noted among patients receiving sulfapyridine. Similar observations were made by Kapnick, Stewart and Lyons, who found a decrease in plasma prothrombin as one of the earliest signs of impending hepatic failure resulting from sulfonamide therapy.

While sulfonamide therapy may cause hepatic dysfunction or less frequently severe damage to the liver, this should not deter any physician from administering sulfonamides when there are clearcut indications for their use. It is believed that sulfadiazine and sulfamerazine are less toxic for the liver than sulfanilamide. There is some evidence that one must be particularly cautious before initiating treatment with a sulfonamide when severe hepatic insufficiency is already present. Even in such cases sulfonamide therapy is warranted when an infection amenable to such treatment is present. This leads up to the question of inaugurating sulfonamide therapy in a patient with an obstructive type of jaundice due to a stone in the common bile duct. Such patients often have hepatic dysfunction and morphologic changes in the parenchyma of the liver. A cholangitis is not uncommon. Sulfonamides, administered orally or parenterally, are excreted into the bile. On the other hand, such treatment is often accompanied by disappointing results. The nature of the infection precludes successful therapeutic results because of the presence of pus, detritus and dead microorganisms which inhibit the action of the compounds. Not infrequently *Escherichia coli* is the predominating species of bacteria present, and some strains are notoriously resistant to the antibacterial action of the sulfonamides. In conclusion, a physician may face the problem of administering a drug that may accentuate hepatic dysfunction and in most instances fail to effect the clinical course of the disease, namely infection associated with choledocholithiasis.

THERAPY OF UNDULANT FEVER

To the Editor:—A case of undulant fever of short duration (to the best of my knowledge about six weeks) fails to respond to vaccine or sulfonamide therapy. Chills, fever (from normal to 100 F. in the morning to 104.5 F. in the afternoon) and severe diaphoresis persist. The vaccine, has been given in 1 cc. doses every third day. So far I have not increased the dose. Sulfathiazole caused nausea and vomiting, sulfadiazine caused headache and sulfanilamide caused severe urticaria, all being given in 1 Gm. doses four times a day. These reactions appeared in thirty-six to forty-eight hours. Sulfadiazine was kept up for three days in spite of headache without any change in the temperature. I have started sulfanilamide again in 0.32 Gm. doses three times a day to see if the urticaria was really due to the drug or to some food allergy. The sulfonamides were accompanied by sodium bicarbonate. Do you have any suggestions?

H. Y. Fredrick, M.D., Westfield, Wis.

ANSWER.—It is difficult to see why vaccine therapy should be of any definite benefit in a case of acute brucellosis of only six weeks' duration. On the other hand, sulfonamide therapy when given in adequate doses for a period of several days has been associated with a termination of fever and the eradication of a bacteremia. Obviously, a correct diagnosis must have been established prior to therapy. This statement is made in view of the fact that, of all the infectious diseases, brucellosis constitutes an infection the diagnosis of which is difficult to establish with certainty unless the organisms have been isolated from the tissues or body fluids.

Favorable therapeutic results in some acute cases have been obtained with any one of the commonly used sulfonamides. Since the patient under discussion appears to tolerate sulfadiazine reasonably well, except for the headaches, this drug may be given in doses so that a blood concentration of at least 10 mg. per hundred cubic centimeters is maintained for at least two weeks. This will usually require an initial dose of 4 Gm. and then 1 Gm. every four hours day and night. In addition, a total of 12 to 15 Gm. of sodium bicarbonate may be given during a twenty-four hour period with an intake of fluid, so that the twenty-four hour output is 1 liter or more. If smaller doses of a sulfonamide are used, such as 0.32 Gm. of sulfanilamide three times a day, there is the possibility that the patient will receive no benefit and that the organisms will become sulfonamide resistant.

If the patient progresses into a chronic illness, without benefit from sulfonamide therapy, artificial fever therapy may be indicated with the use of one of the standard cabinets.

A PANORAMIC VIEW OF THYROTOXICOSIS

REGINALD FITZ, M.D.
BOSTON

In 1923 I became interested in periodic health examinations and determined, for my own satisfaction, to *discover whether or not they were of use*. I believe that the periodic health examination method should be regarded seriously by the man in general practice as an important tool for clinical investigation. In light of present knowledge so little is known of the mode of origin of many diseases that to expect the periodic health examination to be very useful in preventive medicine is unsound. But it affords every doctor an opportunity to observe patients systematically over long intervals of time and thereby enables him to add new bits of medical knowledge.

To explore this idea further I have assembled a small group of patients with toxic goiter studied by this method. My attempt here is to give a narrative of this disturbance as an actual experience in their life cycle. My material consists of a group of 33 patients each of whom was thought not to have toxic goiter when first examined, and many were followed for a number of years after developing it.

THE TYPE OF INDIVIDUAL LIKELY TO DEVELOP TOXIC GOITER

The first point which seemed of interest was an attempt to discover whether any particular type of individual is likely to develop hyperthyroidism or whether it is a medical accident that may happen to any one. In this series there were 3 men. In analyzing the sex distribution in some 500 cases of exophthalmic goiter in Boston, Thompson and Means¹ found that about 20 per cent occurred in males, and Boothby,² reporting from the Mayo Clinic, found that about 15 per cent of the cases there were in the sterner sex; the small sampling reported here is a reasonable one from this particular point of view.

The age range of the group when they were first examined was from 65 years to 15 years, the range in height from 172.5 cm. (5 feet 8 inches) to 151 cm. (4 feet 11 inches) and the range in weight from 97.2 Kg. (214 pounds) to 46.8 Kg. (103 pounds). Therefore when they were "normal" as young or old persons they were either fat or thin and tall or short; even if one had scrutinized them with a most critical eye it would have been impossible to give any tangible

reason from their appearance for thinking that many of them were necessarily predisposed to the later development of thyrotoxicosis.

Six of these persons developed thyrotoxicosis under my own eyes and 4 had been observed periodically for several years beforehand. I knew their families, a good deal about their way of life, their social and financial problems and how they ordinarily seemed to meet the everyday adventures of existence. Only 1 of them might reasonably have been suspected of later developing hyperthyroidism; she was a prominent eyed, nervous young woman, highstrung and tense, and with 2 sisters believed to have thyroid disease.

Because of this experience, microscopic as it is, I find it difficult to agree with Warthin³ and to take recourse to the conception of a special hereditary predisposition to a "Graves' constitution" or with Moschowitz⁴ in his belief that the syndrome of thyrotoxicosis develops preponderantly in patients of the sensitive, emotional type. Rather would I say that thyrotoxicosis is a medical misadventure that may befall any one at any time. It is true that 4 of the patients had brothers or sisters with goiters—raising the familial aspects of the condition. On the whole, however, most goiter experts appear to agree with Means⁵ and with Joll⁶ in believing there is no real evidence that the disease is usually hereditary though inheritance may have a part—and indeed one of some importance—in its background.

THE PRECURSORS OF TOXIC GOITER

Four leads were perhaps suggestive as being precursory to what happened later. As has been mentioned, 4 patients had brothers or sisters with goiters; 7, when they were not toxic, had sufficiently developed thyroid glands to be palpable on ordinary routine physical examination; 13, excluding 2 with unmistakable signs of rheumatic heart disease, had readily audible systolic murmurs over the precordium; and 9, excluding 1 with rheumatic heart disease, had a blood pressure level on first examination higher than 140 systolic. From this meager evidence one might suspect that a "normal" individual who happens to have, when first examined, goiter in his family, a palpable thyroid gland, a precordial systolic murmur and a slightly elevated blood pressure may belong to the type most likely subsequently to develop thyrotoxicosis. But the evidence on this point is very flimsy. Sir Thomas Lewis⁷ once wisely remarked that there is no justification for the not uncommon belief that every patient who has an enlarged thyroid and tachycardia has incipient toxic diffuse

goiter. Certain writers, he said, imbued with recent endocrinologic doctrines, are but too ready to regard every enlarged thyroid gland as an overacting gland; these writers seem unaware how frequently a palpable thyroid is present in soldiers and civilians who suffer from no symptoms.

Seventeen years ago I examined for one of the Boston colleges a group of 110 apparently healthy young women. Of these, 54 (49 per cent) appeared entirely normal, 9 (8 per cent) had a blood pressure reading of more than 140 systolic on casual examination, 27 (25 per cent) had palpable thyroid glands and 33 (29 per cent) had audible systolic murmurs.

TABLE 1.—Findings in a Group of Patients Examined Before They Were Considered to Have Thyrotoxicosis

No.	Sex	Family History of Goiter	Thyroid	Heart	Blood Pressure	Age	Weight, Kg.	Height, Cm.
1	♀	Sister had goiter	Not felt	Systolic murmur	160/90	63	65.5	161.3
2	♀	Negative	Not felt	Negative	130/70	53	97.2	156.5
3	♀	Negative	Not felt	Negative	145/80	57	68.8	167.5
4	♀	Negative	Not felt	Systolic murmur	160/105	55	84.0	163.1
5	♀	Negative	Not felt	Systolic murmur	170/100	53	65.0	152.0

14	♀	Negative	Palpable	Negative	120/70	35	51.5	161.5
15	♀	Negative	Palpable	Negative	140/100	35	71.7	161.4
16	♀	Negative	Not felt	Systolic murmur	120/70	35	75.0	153.5
17	♀	Negative	Not felt	Systolic murmur	160/90	34	75.0	164.0
18	♀	Brother had goiter	Palpable	Negative	100/70	31	50.0	160.3
19	♀	Sister had goiter	Not felt	Systolic murmur	29	166.4
20	♀	Negative	Palpable	Systolic murmur	125/70	27	56.8	167.5
21	♀	Negative	Not felt	Negative	135/80	27	49.5	161.5
22	♀	Negative	Palpable	Negative	115/80	26	57.7	151.4
23	♀	Negative	Not felt	Negative	100/70	25	162.0
24	♀	Negative	Not felt	Negative	120/80	25	63.3	169.5
25	♀	Negative	Not felt	Negative	120/80	24	65.5	171.0
26	♀	Negative	Not felt	Rheumatic heart disease	120/60	24	65.9	162.0
27	♀	Sister had goiter	Not felt	Negative	24	56.8	162.6
28	♀	Negative	Palpable	Rheumatic heart disease	140/70	23	61.5	168.4
29	♀	Negative	Not felt	Systolic murmur	105/80	20	52.3	163.2
30	♀	Negative	Not felt	Negative	115/75	20	57.3	165.0
31	♀	Negative	Not felt	Systolic murmur	106/70	19	55.5	153.5
32	♀	Negative	Palpable	Negative	110/70	17	66.5	158.0
33	♂	Negative	Not felt	Systolic murmur	100/60	15	168.7

The combination in different individuals of murmurs, palpable glands and increased blood pressure varied greatly; one young woman had all these findings, lacking only a history of goiter in her family to make of her a reasonable suspect according to this way of reckoning. During the past seventeen years she has married, has had three children and up to the present time has not developed hyperthyroidism.

THE EARLY MANIFESTATIONS OF TOXIC GOITER

A second interesting point was the manner in which the manifestations of thyroid toxicity seemed to become evident. Six patients appeared to develop symptoms of thyrotoxicosis suddenly: after infection in 2 instances, after an attack of asthma in another, after the mental shock of her husband's death in a fourth case, and for no obvious reason in the fifth and sixth. The 28

others, in contrast, appeared to develop symptoms uncomfortable enough to make them seek medical advice for hyperthyroidism with varying degrees of insidiousness—indeed so insidiously in 4 cases that the diagnosis was established through an incidental finding of an elevated metabolic rate only after prolonged observation lasting over a period of several years.

The possible role of infection in awakening thyrotoxicosis is so well recognized as not to be worth mentioning; certainly almost any infection may bring to light latent hyperthyroidism and may exaggerate the fully developed condition. Rosenow⁸ is the only bacteriologist who has claimed to find a specific organism that might produce it, and his observations have never received very serious consideration.

The relation of asthma to hyperthyroidism also has been commented on repeatedly. Indeed, Widal and Abrami⁹ once claimed that the asthmatic hyperthyroid could often be cured of asthma by irradiation of the thyroid gland, an observation which has not received wide confirmation.

Mental shock as a trigger mechanism is always brought up in discussions on the exciting causes of thyrotoxicosis. Bram¹⁰ believed that he discovered evidence of psychic trauma in 85 per cent of his cases; on the other hand, no great increased incidence of the disease was reported in England as an aftermath of the war of 1914-1918 when conditions might well have stimulated it, and no writer has yet claimed to prove that the weight of worry and emotional strain imposed on those developing thyrotoxicosis is measurably heavier than that imposed on the general population. Therefore it seems that all there is to say is that what actually caused hyperthyroidism to develop in any of the cases reported here is entirely unknown, just as is true of other cases described in the literature.

The age at which these patients developed thyrotoxicosis covered a wide span of years, but the majority developed it in the third and fourth decades. This also is typical, according to the tables of Thompson and Means¹ and the statistical analysis of Gardiner-Hill.¹¹

The physical changes that were encountered are readily predictable; in almost every instance there were varying degrees of thyroid enlargement, tachycardia, elevated pulse pressure and presence of a precordial systolic murmur or its exaggeration had it been audible previously.

The amount of weight loss varied. One patient lost 30 kilograms (approximately 66 pounds) in a short space of time, whereas others showed relatively little in the way of weight loss. The data on this point are unconvincing, since many of the patients were examined as "normal" individuals several years before they had hyperthyroidism and thus their exact weight when symptoms of thyrotoxicosis began is not known.

In glancing at the table the most striking feature noted is the frequency with which symptoms related to the cardiovascular system were encountered. The combination of nervousness—at best an ill defined term—breathlessness, palpitation and even cardiac decompensation was not infrequently found. This fact is worth emphasizing, because in the modern clinic

TABLE 2.—*The Apparent Mode of Onset by Which Thyrotoxicosis Was Recognized and the Obvious Changes It Produced*

Case No.	Thyroid Palpable		Systolic Murmur		Blood Pressure		Age		Weight		Basal Metabolic Rate	Comment
	Before	After	Before	After	Before	After	Before	After	Before	After		
1	No	Yes	Yes	Yes	160/90	160/93	65	66	65.5	64.9	+21	Gradual onset of weakness and nervousness complicated by auricular fibrillation
2	No	Yes	No	Yes	130/70	140/80	58	63	97.2	66.3	+51	Became suddenly nervous at death of her husband and this exaggerated by death of her son; rapid loss of weight
3	No	Yes	No	Yes	145/80	180/70	57	60	63.8	62.6	+38	Gradual onset of shortness of breath and easy fatigue with nervousness
4	No	Yes	Yes	Yes	160/105	190/110	55	63	84.0	61.5	+53	Gradual onset of nervousness and weight loss apparently following an upper respiratory infection
5	No	Yes	Yes	Yes	170/100	185/115	53	59	65.0	65.0	+53	Gradual onset of nervousness and exophthalmos
6	No	Yes	No	Yes	160/90	185/115	46	59	.	65.9	+27	Gradual onset of nervousness and later exophthalmos
7	No	Yes	Yes	No	140/70	190/100	44	53	46.8	45.3	+70	Gradual onset of nervousness, developed later thyroid enlargement and exophthalmos
8	No	No	No	No	110/70	110/60	43	51	67.0	68.5	Precordial pain; basal metabolic rate of +60 an incidental finding
9	No	Yes	No	No	130/80	150/60	43	49	54.5	56.7	+55	Suddenly noticed nervousness and tachycardia after respiratory infection; a few months later became conscious of goiter
10	No	Yes	Yes	Yes	135/100	130/70	39	46	66.5	52.0	+52	Gradual onset of indigestion, later complicated by enlargement of thyroid, nervousness and palpitation
11	No	No	Yes	Yes	140/100	116/70	38	41	49.5	39.0	+53	Had symptoms of cardiac decompensation, exophthalmos noted; thyrotoxicosis discovered by basal metabolic rate
12	No	No	No	Yes	110/70	125/60	38	43	83.5	71.7	+24	Basal metabolic rate —18 when first seen; gradual onset of fatigue, nervousness and weight loss
13	No	Yes	No	Yes	120/70	150/62	36	43	54.6	45.4	+52	Basal metabolic rate +8 when first seen; sudden onset of nervousness, palpitation and weight loss at time of menopause
14	Yes	Yes	No	No	120/70	130/64	35	36	51.5	48.1	+34	Sudden onset of swelling of thyroid following tonsillitis with nervousness, tachycardia, exophthalmos and weight loss
15	Yes	Yes	No	Yes	140/100	130/90	35	40	71.7	63.0	+23	Gradual onset of nervousness, tremor and tachycardia
16	No	Yes	Yes	Yes	120/70	150/70	35	37	75.0	65.8	+32	Gradual onset of nervousness, tachycardia and weight loss
17	No	Yes	Yes	Yes	150/90	160/90	34	37	75.0	48.2	+62	Sudden onset; became suddenly nervous, developed palpitation and great loss of weight after an attack of asthma
18	Yes	Yes	No	Yes	100/70	130/70	31	33	56.0	57.2	+41	Basal metabolic rate —2 when first seen; gradual onset of increasing nervousness and tachycardia
19	No	Yes	Yes	Yes	..	125/70	29	30	60.5	+25	Gradual onset about six months before entry to hospital of nervousness, weariness, development of goiter and exophthalmos
20	Yes	Yes	Yes	Yes	125/70	130/70	27	29	56.8	55.0	+46	Basal metabolic rate +9 when first seen; gradual onset of increasing nervousness with palpitation and increase in size of thyroid
21	No	Yes	No	Yes	135/80	175/90	27	38	49.5	51.8	+60	Gradual onset of increasing nervousness, fatigue and palpitation; loss of 4 Kg. in weight from maximum before illness began
22	Yes	Yes	No	No	115/80	132/70	26	39	57.7	60.5	+20	Gradual onset of nervousness and loss of weight (18.2 Kg. from maximum during interval)
23	No	?	No	No	100/70	120/50	25	28	62.2	+28	Gradual onset of fatigue, tremor and palpitation
24	No	Yes	No	No	120/80	120/60	25	29	65.8	68.5	+40	Gradual onset of nervousness and undue fatigue complicated by slight diarrhea; finally noticed swelling in neck

patients with hyperthyroidism masked by some other disease are the least easily recognized.

On the whole, there was nothing particularly remarkable about any of the cases and they add nothing new. They developed hyperthyroidism acutely or slowly; evidently it is a difficult matter to recognize "early" hyperthyroidism, probably because a patient developing it is at first stimulated and may feel unusually well. Only after it exists for some time so as to wear a patient down or unless it is notably acute does it make any one feel ill enough to seek medical advice, and by this time usually it is easily recognized.

TABLE 3.—Cases of Thyrotoxicosis with Recovery

Case No	Treatment	Date of Present Note	Comment
4	Subtotal thyroidectomy	4 years after operation	Feels well; has gained 15.5 Kg.
5	Subtotal thyroidectomy	17 years after operation	Death from abdominal carcinomatosis; at no time since operation any symptoms of hyperthyroidism
8	Subtotal thyroidectomy (thyrocardiac)	10 years after operation	Death in heart failure; at no time since operation any symptoms of hyperthyroidism
9	Subtotal thyroidectomy	19 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism; has gained 58 Kg
11	Subtotal thyroidectomy (thyrocardiac)	14 years after operation	Death in heart failure, at no time since operation any symptoms of hyperthyroidism
12	Iodine therapy alone	12 years after hyperthyroidism suspected	Continues well; no symptoms of recurrence; no change in weight
14	Subtotal thyroidectomy	11 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism; has gained 8.2 Kg.
20	Subtotal thyroidectomy	4 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism
22	Subtotal thyroidectomy	14 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism; has gained 8.6 Kg
23	Irradiation	18 years after hyperthyroidism suspected	Feels well; at no time since treatment any symptoms of hyperthyroidism
24	Subtotal thyroidectomy	17 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism; has gained 11.4 Kg.
28	Subtotal thyroidectomy (thyrocardiac)	7 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism; no change in weight
29	Subtotal thyroidectomy	11 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism; has gained 10 Kg
33	Subtotal thyroidectomy	6 years after operation	Feels well; at no time since operation any symptoms of hyperthyroidism; has gained 23.8 Kg; basal metabolic rate -7

THE IMMEDIATE RESULTS OF TREATMENT IN TOXIC GOITER

The third and most interesting point is what happened to the patients after they developed hyperthyroidism. Strangely enough, this is difficult to evaluate and is largely a matter of individual conjecture. In the days before the chances of successful surgery were as good as they now are and operations were not popular, clinicians paid much attention to the natural history of the disease. Its relapsing character was well recognized, and as long ago as 1913 H. S. Plummer¹² attempted to show that relapses and remissions tended to occur in fairly regular cycles and that consideration of this should play a part in the wisest choice of therapy. A few years later Barker¹³ introduced the thought that thyrotoxicosis, no matter how it is treated, tends to "burn itself out," whatever that phrase may

mean, and this tendency toward spontaneous improvement of symptoms must play a part in evaluating therapeutic results. Going back into even more ancient days, one can easily find observers who thought that the natural history of thyrotoxicosis was to end in myxedema and others who felt that complete recovery was the rule unless the patient died first of heart failure or vascular disease or from some intercurrent infection. Thus almost anything that may happen to a patient under treatment has been previously reported as part of the ordinary behavior of the disease, and all this makes the proper evaluation of therapeutic results the more difficult.

As thyroid surgery was developed, pathologists had opportunity to study thyroid glands removed under a variety of clinical conditions. It is bewildering to read descriptions of thyroid histology in connection with thyrotoxicosis and even more bewildering to attempt to compare the illustrations that have been used to demonstrate the different changes that have been described. In this country our pathologists in the main seem to be agreed that in the toxic glands they study there are likely to be changes in the character of the epithelium lining the acini and in the colloid, and that these changes are accompanied or followed by more or less fibrosis and infiltration of lymphocytes so that the normal architecture of the gland is altered in the direction of a chronic inflammatory process. They also agree that the age of the patient, the part of the country from which he comes and the duration of his hyperthyroidism bear a relation to what they see; and they know from the very convincing work of Rienhoff¹⁴ that the administration of iodine to the hyperplastic gland can produce recognizably regressive changes in its appearance. Beyond this point the going is harder, the underlying thyroid pathology of thyrotoxicosis is less certain, the various classifications of hyperplastic goiters are more difficult to appreciate and, to end up with, there are only the rarest reports of what the treated thyroid gland looks like at the patient's death.

When results of treatment are evaluated by clinicians, one runs afoul of uncertainty regarding the criteria that are used. It is clear that with any treatment two unpleasant happenings are encountered with varying degrees of frequency: the development of post-therapeutic hypothyroidism or of recurrences of thyrotoxicosis. And even in the cases that are reported as having been "cured" the definition of "cure" is debatable. Rasmussen¹⁵ has written an interesting paper in which he reminds us that because a patient with thyrotoxicosis subsequently develops a normal rate of metabolism, gains weight and is able to resume his work, yet no "cure" need have been accomplished. For such patients, he believes, are likely to be left with residual changes in personality and nervous makeup which he regards as part of the thyrotoxic syndrome and which he thinks are enduring and fully as disturbing as the metabolic aspects of the disorder.

Greene and Hurxthal¹⁶ have suggested a follow-up plan for the study of goiter which is admirable. In speaking of recurrences they say that to report a certain number of these episodes among a group of cases

within a given period of time does not mean much, for the chances of later recurrences are by no means ended. The final estimate of what thyrotoxicosis is and what it does to a patient cannot be made until the whole life history of that individual is known. It is from this point of view that I have attempted to study the cases in my particular group.

Four patients have been lost track of, and 1 developed a fatal postoperative thyroid crisis. Thus only 28 of the series yield information as to the late effects of thyrotoxicosis.

Table 3 summarizes the apparently satisfactory results obtained in 14 cases. All but 4 of the patients were followed for ten years or more after the diagnosis of hyperthyroidism was established, so that temporarily beneficial effects of treatment have not been included. Case 8 is of especial interest because the thyroid gland was examined by the pathologist when it was hyperactive and ten years later when the patient died.

THE END RESULTS OF TOXIC GOITER TREATED BY SURGERY

M. W. first entered the Peter Bent Brigham Hospital when he was 43 years old, a previously healthy business man who consulted the hospital for pain in his flank. He weighed 67 Kg. His neck was in no way remarkable. His heart seemed normal. His blood pressure was 110/70. He was found to have a double inguinal hernia, and it was suspected that he had a renal calculus.

He reentered eight years later. During the interval he had developed attacks of choking sensations at night and of precordial pain by day brought on by exertion. About eight weeks previously he had suffered a coronary occlusion.

He now weighed 68.5 Kg. The thyroid was not enlarged and still appeared in no way remarkable. The blood pressure was 108/62. There were no cardiac murmurs, though now the heart seemed slightly enlarged. An electrocardiographic tracing showed an abnormal form of ventricular complex. The basal metabolic rate was increased, falling with iodine from +60 to +40.

He had a successful subtotal thyroidectomy performed in two stages with a satisfactory drop in metabolic rate to -8. Microscopic examination of the gland revealed a picture entirely characteristic of primary hyperplasia.

Ten years after these operations and eighteen years after his first entry to the Peter Bent Brigham Hospital he returned there. He had felt entirely well until a year previously, having nine years of relief from all symptoms referable to his heart. Then, little by little, he noticed a sense of heaviness in his legs and of undue fatigue on exertion, soon followed by what he termed "uncomfortable spells" after a large meal and finally, for a few weeks, by attacks of nocturnal dyspnea accompanied by a feeling of tightness in his chest.

His weight now was 74.2 Kg. The thyroid was not palpable. The blood pressure was 130/90. There were no cardiac murmurs, though the heart had become notably enlarged. An electrocardiographic tracing gave curves typical of left bundle branch block. The basal metabolic rate was +14; the complete accuracy of this test is open to question since the patient found the mask difficult to bear, and thus probably the reported figure is higher than actually obtained. He died of heart failure after remaining in the hospital for nearly a month.

The thyroid gland weighed 11 Gm. On microscopic examination the picture was that of notable inactivity. The acini were dilated and filled with dense basic staining colloid. The epithelium was low cuboidal. At the periphery of the gland were small atrophic acini with desquamated epithelium.

It is remarkable how difficult it is to find case reports such as this. Here subtotal thyroidectomy induced symptomatic relief for the rest of the patient's life and

from that point of view represented a cure. Yet the thyroid gland after the operation did not regenerate and grow to look like the normal thyroid of a 61 year old man. On the contrary, it gave every appearance of atrophy and, had life continued long enough, might well have finally caused what Sir William Gull¹⁷ termed "a cretinoid state supervening in adult life." Scarcello and Goodale¹⁸ reported a somewhat similar case. Their patient, a young woman, had in 1926 "primary hyperplasia of the thyroid gland, follicular type," with a basal metabolic rate of +41. Subtotal thyroidectomy was performed. She died thirteen years later, eventually developing clinical myxedema. They found that the thyroid now was chiefly represented by disorganized masses of Hürthle's cells with lymphocytic

Fig. 1.—End result on the thyroid gland of thyrotoxicosis treated by surgery: Section of thyroid gland removed at operation, reduced from a photomicrograph with a magnification of 50 diameters. The gland is diffusely hyperplastic. There are numerous areas of epithelial hyperplasia with the formation of papillary projections. There is moderate general increase of connective tissue throughout. (Courtesy of Drs. Shields Warren and S. B. Wolbach.)

infiltration about them. Are such findings the usual pathologic end results of thyrotoxicosis treated by surgery and, if so, do they represent the best that can be hoped for?

THE SIGNIFICANCE OF THE FEBRILE REACTION IN INFLUENZA

WINGATE M. JOHNSON, M.D.

AND

CHARLES H. REID JR., M.D.

WINSTON-SALEM, N. C.

Some years ago one of us¹ in a paper on influenza said "One very firm impression I have formed, though I have no statistics to confirm it, is that the higher the initial temperature, the more quickly it is apt to subside."

This impression crystallized gradually as a result of repeated epidemics following the great pandemic of 1918-1919 and was emphasized by the experience of 1 patient in particular. This woman, a nurse, had an attack of influenza every January for five or six consecutive years. Every attack except one began insidiously and the temperature rarely exceeded 100 F., more often remaining under 99 F. Her stay in the hospital varied from twelve to fifty-six days, and an additional month was usually needed to make her fit for duty. Finally she had an attack which began with a sudden onset and a temperature of 102.6 F. The fever lasted less than two days. This time she was a hospital patient for only five days, and a week from the onset she was back on duty in good condition. The temperature curve shown in chart 1, although that of another patient, is almost identical with hers on that occasion.

In an effort to determine whether there is any ground for the impression that a high initial temperature is a good prognostic sign in influenza, a study of 50 cases of uncomplicated influenza was carried out at the North Carolina Baptist Hospital during the epidemic in the winter of 1943-1944.

Our criteria for making a diagnosis of influenza included pharyngitis, malaise, fever, chills or chilly sensations, backache or aching pains elsewhere, asthenia and a low or normal leukocyte count. The leukocyte count averaged approximately 6,000 per cubic millimeter, the highest count being 9,000 and the lowest 2,400. It is of passing interest that the 4 patients in the series who were treated with sulfonamides (sulfadiazine and sulfamerazine) had an average leukocyte count of only 3,900.

Half of the cases studied (group A) had a relatively sudden onset, while the other half (group B) were relatively insidious in onset. The 25 patients in the latter group had prodromal symptoms for one-half to three days before being actually confined to bed. The others became quite ill

within a twelve hour period. In all cases the maximum fever was reached within the first three days of the disease, and usually on the first day. Frank chills were more common in the group which had a sudden onset of symptoms.

From the Department of Medicine, Bowman Gray School of Medicine of Wake Forest College, and the North Carolina Baptist Hospital.
1. Johnson, W. M.: Influenza: Some Observations and Impressions, *South. Med. & Surg.* 98: 513-517 (Oct.) 1936.

The fact of major interest to us was the much more pronounced febrile response shown by the patients who had a sudden onset of symptoms. The temperature curve of A. K. (chart 1) is typical of this group of patients. The average maximum temperature in this group was 102.1 F. as compared with an average maximum temperature of 100 F. in group B (chart 2). In the former group the average duration of fever (temperature over 99 F.) was only 1.84 days, but in the latter group the average was 2.08 days. Although this difference is slight, it does indicate that high fever in uncomplicated influenza is not a bad prognostic sign.

Of more significance is the difference in the length of hospital stay for the two groups. The average period of hospitalization for the patients with the higher febrile response and sudden onset of symptoms was approximately two days shorter than that for those in group B. The average length of hospital stay for the patients in group A was only 4.88 days, as opposed to 6.44 days for the other group.

According to the Committee on the Costs of Medical Care, upper respiratory infections (including influenza) are responsible for approximately 62 per cent of disabling illness. It might be emphasized at this point that, after the period of complete disability caused by influenza is over, there is still a relatively long period of partial disability due to the so-called asthenic state. It was generally observed that the asthenic state persisted much longer in the group with the lower febrile response. Two patients in this group are known to have had relapses after discharge from the hospital, requiring at least an additional week of bed rest.

In view of the apparently more rapid recoveries from influenza in the group of patients showing the greater febrile response, we hope that fever therapy may be tried in a series of test cases during a future epidemic.

SUMMARY AND CONCLUSIONS

A series of 50 cases of influenza, 49 of which occurred during the winter of 1943-1944, have been studied.

Exactly one half of the cases were sudden in onset (group A), while the remaining half began insidiously (group B).

In group A an average maximum temperature of 102.1 F. was encountered, while in group B the maximum was only 100 F.

The average hospital stay for group A was 4.88 days, while for group B it was 6.44 days.

The postinfluenza asthenic state was apparently more pronounced in group B, and at least 2 of the 25 patients in this group suffered relapses after discharge from the hospital.

Well controlled fever therapy may be of value in circumventing the asthenic state.

Sulfonamides are not indicated in uncomplicated influenza and apparently serve to enhance the preexisting leukopenia. Unless daily leukocyte counts can be done, the use of sulfonamides in uncomplicated influenza is contraindicated.

IMMUNITY RESPONSES TO MIXTURES
OF DIPHTHERIA TOXOID AND
PERTUSSIS VACCINE

LOUIS W. SAUER, M.D.

WINSTON H. TUCKER, M.D.

AND

EVA MARKLEY, R.N.

EVANSTON, ILL.

The routine injection of diphtheria toxoid during the latter part of the first year of life has almost completely eliminated diphtheria in most localities; and, during the time that infants after the age of 7 months have been injected with potent pertussis vaccine, whooping cough morbidity and mortality have decreased at an encouraging rate.

Because diphtheria and whooping cough are most prevalent and serious in the first years of life, it seemed logical that immunization against the two diseases should be attempted at the same time by the injection of mixtures of diphtheria toxoid and potent pertussis vaccine. When this investigation was begun in 1938 only Bordet¹ had published a brief report on the use of a mixture; but he gave no data on immunity tests for either disease nor did he report clinical evidence of protection.

A satisfactory mixture of these antigens when injected subcutaneously should not be followed by a severe systemic or local reaction. It should produce a high incidence of prolonged protection against each disease. The duration of immunity should approximate that when each antigen is injected singly (at different times) or when injected simultaneously (separately). The component antigens should be stable for at least a year. If effective, the number of injections for the protection against these two diseases could thus be cut in half. The mixture should be safe for general use in institutions, health department clinics and private practice.

In a preliminary paper in 1941 we² reported the simultaneous administration of diphtheria toxoid and pertussis vaccine in young children. The antigens were administered in separate syringes or mixed in the same syringe. At the Evanston Health Department Immunization Clinic three doses of the two antigens were injected at the same time into 464 infants, beginning at 8 months of age. Because the negative Schick test and the 3 plus or 4 plus pertussis complement fixation test had been accepted by the greatest number of investigators as evidence of adequate diphtheria and pertussis antibody responses, we used them as evidence of conferred protection. It had been found³ that an appreciable percentage of infants did not develop antibodies from three doses of potent pertussis vaccine injected subcutaneously before 6 months of age at weekly intervals.

Systemic (febrile) and local reactions occurred in a small percentage of cases as they did with plain per-

tussis vaccine (15,000 million bacilli per cubic centimeter). Schick tests were read seventy-two hours after 0.1 cc. of Schick test material was injected intracutaneously on the flexor surface of the forearm. Diphtheria antitoxin concentration levels were determined early in the study, but the determinations were discontinued after it was found that they usually coincided rather closely with the Schick test readings. Pertussis agglutination tests (Mathieson technic and the rapid slide method) were performed but were excluded because the peak occurred weeks later than that of the complement fixation tests.

The preliminary Schick test (before the first injection) was positive in 96 per cent of the infants; the preliminary pertussis complement fixation test⁴ was negative in 95 per cent. When retested six weeks after the final dose, infants injected simultaneously (antigens separate) showed 98 per cent of the Schick tests negative, and 91 per cent had 3 plus or 4 plus complement fixation. Infants injected with the mixed antigens showed 95 per cent of the Schick tests negative, and 73 per cent had 3 plus or 4 plus complement fixa-

† One hundred per cent of the infants with complement fixations less than 3+ became 3+ or 4+.

tion. After a "stimulating" dose of 2 cc. of plain pertussis vaccine (15,000 million bacilli per cubic centimeter) all infants who had less than 3 plus acquired 3 plus or 4 plus complement fixation. Forty-four infants who had had negative Schick tests and 3 plus or 4 plus complement fixation after the injection of mixed antigens were retested one to two years later. Their Schick tests and pertussis complement fixation tests still showed high immunity responses; reversion of the tests had not occurred. Up to July 1944 none of these 464 infants inoculated between 1938 and 1941 were known to have developed either disease.

The investigation has been continued to determine which mixture, dose and time interval gave the highest immunity response without severe reactions. Various

4. To obtain blood from young infants for the complement fixation or agglutination tests, the infant lies on the abdomen. A foot (or hand) should be warm. The big toe or middle finger is rubbed with a sterile gauze square saturated with 70 per cent alcohol, then dried with sterile gauze. A large Hagedorn needle (4½ inch) is removed from 70 per cent alcohol and wiped dry on sterile gauze. Just before the skin is pricked the toe or finger is constricted with the left thumb and index finger. With the cutting edge upward the needle pricks deeply opposite the base of the nail about 0.5 cm. from the lateral margin of the nail. The needle is brought upward toward the tip of the toe or finger, so that the incision is superficial where the needle leaves the skin. After the required amount of blood has dripped into a sterile tube, the incision is compressed with sterile gauze, as the foot (or arm) is raised. At the moment when the pressure is removed, a half width mercurochrome handy tape is wrapped around the toe (or finger) at the incision. The dressing is kept dry and not removed within two days. This method, suggested by Dr. Daughtry-Denmark, has been used for years. Infection has never occurred.

mixtures (plain and alum precipitated), various time intervals (one to four weeks) between the three doses, and various time intervals (six to twelve weeks) between the final dose and the immunity tests were used. An additional 1,507 infants were given injections at the Evanston Health Department Immunization Clinic and at St. Vincent's Infant and Maternity Hospital (Chicago). Of these, 648 were included in the tables.⁵ All were more than 7 months of age when the injections were begun. The average age was about 8 months. Injections were made in alternate upper arms, starting with the left. To retard absorption, to produce a maximum response and to lessen systemic (febrile) reactions, the separate (simultaneous) injections and the mixed (plain) injections were given superficially (just under the skin), so that a lump was visible at the site of injection. It was found that the alum precipitated mixture caused less frequent fluctuating areas (sterile abscess) when each dose was injected more deeply under the skin of the upper arms, with the needle directed distally. Practically the only interruption in the regular administration of the injections occurred in infants who contracted intercurrent diseases or who moved away. Those who failed to complete the series of injections were not included in the final tabulations.

STANDARD DIPHTHERIA TOXOID AND PERTUSSIS VACCINE, SEPARATE (SIMULTANEOUS)

In this series 1, 1 and 1 cc. doses of standard diphtheria toxoid and 2, 2 and 3 cc. doses of pertussis vaccine (15,000 million bacilli per cubic centimeter) were injected separately (simultaneously), with a weekly interval between the doses at St. Vincent's Orphanage and a three week interval at the Health Department Clinic. To determine when the peak of the 3 plus or 4 plus complement fixation test was reached, follow-up pertussis complement fixation tests were performed at one, three, six and twelve weeks after the final dose.

TABLE 2.—Immunity Responses After Diphtheria Toxoid and Pertussis Vaccine, Mixed

3 plus or 4 plus positive tests when retested three weeks after a "stimulating" dose of pertussis vaccine (2 cc of 15,000 million bacilli per cubic centimeter). None are known to have acquired either disease.

STANDARD DIPHTHERIA TOXOID AND PERTUSSIS VACCINE, MIXED⁶

In this series 2, 2 and 3 cc. of mixed antigens (0.5 cc. standard diphtheria toxoid and 15,000 million bacilli per cubic centimeter pertussis vaccine) were injected at one week intervals at St. Vincent's Orphanage and at three week intervals at the Health Department Clinic. The Schick test was negative in 91 per cent of infants injected at weekly intervals and in 97 per cent of the three week group. Three plus or 4 plus complement fixation occurred in 66 per cent of the one week interval group and in 72 per cent of the three week group. The weekly interval between the three doses was discontinued when the pertussis immunization response was found low. Ninety-five per cent of the infants of the three week group with complement fixation tests less than 3 plus became 3 plus or 4 plus when retested three weeks after the injection of a "stimulating" dose of pertussis vaccine (2 cc. of 15,000 million per cubic centimeter).

A total dose of 6 cc. (1, 2 and 3 cc.) of the mixed antigens was then injected into a group of infants at one month intervals. The pertussis immunization

6 The mixed antigens used in this investigation were prepared according to our detailed specifications, from 5 to 7 strains of H. pertussis recently isolated and standard diphtheria toxoid, by Parke, Davis & Co., Detroit. The bacilli were grown on Bordet Gougon medium containing defibrinated human (not animal) blood. Fresh "packed" red cells, obtained from the plasma bank, were diluted with an equal volume of sterile isotonic solution of sodium chloride (0.85 per cent). The growth was scraped from the cultured medium, suspended in 0.85 per cent salt solution containing merthiolate 1:5,000. After refrigeration at 5 to 10 C for several weeks it was cultured for sterility and examined microscopically for absence of contaminants. Each lot was standardized to contain 30,000 million pertussis organisms per cubic centimeter. An equal volume of diphtheria toxoid was added to the suspension so that 1 cc of the final concentration contained 0.5 cc of standard diphtheria toxoid and 15,000 million pertussis organisms. The alum precipitated mixture contained 10,000 million bacilli per cubic centimeter. Recently a new concentration containing 30,000 million bacilli per cubic centimeter has been used. A dose required half the volume (0.5 cc) and the local reactions were less severe.

response equaled that after the total dose of 7 cc. (2, 2 and 3 cc.) injected at three week intervals. A total dose of 6 cc. (containing a total of 3 cc. of standard toxoid and 90,000 million pertussis bacilli, i. e. 0.5 cc. standard diphtheria toxoid and 15,000 million bacilli per cubic centimeter), injected in 1, 2 and 3 cc. doses, at one month intervals, became the standard procedure when the plain mixture was used. No instance of severe systemic (febrile) or local reaction was reported. No infant in either group is known to have developed either disease.

ALUM PRECIPITATED DIPHTHERIA TOXOID AND PERTUSSIS VACCINE, MIXED

In this series 1, 1 and 1 cc. of alum precipitated mixed antigens (0.5 cc. of standard diphtheria toxoid and 10,000 million bacilli per cubic centimeter pertussis vaccine) were injected at one week intervals at St. Vincent's Orphanage and at three week intervals at the Health Department Clinic. The total dose of the pertussis vaccine was 30,000 million bacilli. Three plus or 4 plus pertussis complement fixation reactions occurred in a higher percentage of infants than when the plain mixture (total dose of 90,000 million bacilli) was used.

TABLE 4—The Effect of Time Interval on Immunity Responses

Number Children Tested	Interval Between 3 Doses, Weeks	Total Dose	Negative Schick Test, per Cent	3+ or 4+ Pertussis Complement Fixation, per Cent
100	1	3 cc. separate diphtheria toxoid and 7 cc. H. pertussis vaccine (15,000 million bacilli per cubic centimeter)	91	69
98	3	3 cc. separate diphtheria toxoid and 7 cc. H. pertussis vaccine (15,000 million bacilli per cubic centimeter)	97	97
32	1	7 cc. mixed diphtheria toxoid and H. pertussis vaccine (15,000 million bacilli per cubic centimeter)	91	63
70	3	7 cc. mixed diphtheria toxoid and H. pertussis vaccine (15,000 million bacilli per cubic centimeter)	97	72
103	1	3 cc. alum precipitated diphtheria toxoid and H. pertussis vaccine (10,000 million bacilli per cubic centimeter)	83	77
139	3	3 cc. alum precipitated diphtheria toxoid and H. pertussis vaccine (10,000 million bacilli per cubic centimeter)	98	93
97	4	3 cc. alum precipitated diphtheria toxoid and H. pertussis vaccine (10,000 million bacilli per cubic centimeter)	93	94

The Schick test was negative in 83 per cent of the one week group and in 98 per cent of the three week and one month groups. Three plus or 4 plus complement fixation occurred in 77 per cent of the one week interval group, in 93 per cent of the three week interval group and in 94 per cent of the one month interval group.

All infants with complement fixation tests less than 3 plus became 3 plus or 4 plus when retested three weeks after a "stimulating" dose of pertussis vaccine (2 cc. of 15,000 million bacilli per cubic centimeter). No infant is known to have contracted either disease.

THE TIME INTERVAL FACTOR

Zoeller⁷ found a higher immunity response when the three doses of diphtheria toxoid were injected at three week intervals than when three equivalent doses were injected at weekly intervals. To determine whether the immunity response for each component antigen was higher with the three week interval than with the one week interval between the three doses, the infants were injected at one week intervals at St. Vincent's and at three week intervals at the Evanston Health Department Clinic. The percentage of negative Schick tests and 3 plus and 4 plus complement fixation for the two groups were summarized (table 4). In each of the three series (the simultaneous, the plain mixed and the alum precipitated antigens) the three week intervals between the three doses yielded a higher percentage of negative Schick tests than when the doses were given at one week intervals. Likewise, in each of the three series the pertussis complement fixations were more frequently 3 plus or 4 plus when the doses were injected at three week or one month intervals than they were after the one week interval between the three doses.

COMMENT

Systemic (febrile) reactions were transient and usually mild: the rectal temperature occasionally reached 102 F., rarely rose higher and was down within thirty-six hours. Local reactions took place in a small number of instances with a fluctuating area at the site of injection (sterile abscess) after the alum precipitated mixture, especially when injected at weekly intervals. Approximately 2 per cent of the injections were followed by such a local reaction.⁸

Simon and Craster⁹ were the first to report on the use of an alum precipitated mixture of the two antigens. They gave two injections of 1 cc. each, containing 10,000 million bacilli per cubic centimeter of "washed" (Kendrick-Eldering type) pertussis vaccine. Within eighteen months 4 of the 11 children known to have been exposed contracted whooping cough. They recommended four 1 cc. doses at monthly intervals. Since then Daughtry-Denmark¹⁰ and Kendrick¹¹ have published reports on the use of alum precipitated mixtures of diphtheria toxoid and pertussis vaccine. In his book "Whooping Cough" Lapin¹² said "The whole subject of mixed immunizations obviously requires a long follow-up period to determine which method retains antigenicity for a long time. . . . My own experience with combined pertussis vaccine-diphtheria toxoid, alum precipitated, and with a combined pertussis vaccine-diphtheria and tetanus toxoid, alum precipitated, has been disturbing in that a large percentage

7. Zoeller, C.: Bacille diphtérique, in Natan Larrier, L.: *Traité de microbiologie*, Paris, Gaston & Cie, 1934, vol. 2, p. 88.

8. In a recent discussion on the inject on of alum precipitated antigens, J. F. Leake said (Vaccines and Serums: Indications and Procedure, J. A. M. A. 121: 852 [March 13] 1943) "In using alum precipitate, put the needle parallel with the humerus, so that the injection is as deeply subcutaneous as possible. It remains there and sometimes becomes fluctuant. If some physician who doesn't understand these things sees it, it may be incised. It shouldn't be incised. They are not abscesses. They will go away, in general, with practically no attention at all." After using this technique fewer fluctuating areas occurred, but usually a subcutaneous nodule could be palpated for more than three weeks at the site of each alum injection.

of severe reactions and alum abscesses were produced. Any public health measure must balance superior antigenicity against frequency and severity of reactions." The Committee on Therapeutic Procedures of the American Academy of Pediatrics¹³ cautioned "More local reactions are apt to occur after combined vaccine injections, especially of the alum precipitated toxoids. There is a sharp sensation felt after the injection, and local redness comes on with pain. Nodulation is extremely common and abscesses may occur." Notwithstanding an occasional fluctuating area, many pediatricians prefer alum precipitated antigens because the volume of each dose is small. When standard diphtheria toxoid and pertussis vaccine, mixed, is used a "stimulating" dose of 2 cc. of pertussis vaccine (15,000 million bacilli per cubic centimeter) may be injected subsequently, preferably before the child enters school.

SUMMARY

1. After standard diphtheria toxoid and pertussis vaccine, mixed, 97 per cent of the infants, injected with three doses at three week intervals, had negative Schick tests; 72 per cent had 3 plus or 4 plus pertussis complement fixation.

2. After a "stimulating" dose of 2 cc. of pertussis vaccine (15,000 million bacilli per cubic centimeter) 95 per cent of the infants with less than 3 plus pertussis complement fixation after standard diphtheria toxoid and pertussis vaccine, mixed, developed 3 plus or 4 plus reaction.

3. After alum precipitated diphtheria toxoid and pertussis vaccine, mixed, 98 per cent of the infants injected with three doses at three week intervals had negative Schick tests; 92 per cent had 3 plus or 4 plus pertussis complement fixation.

4. A fluctuating area (sterile abscess) followed 2 per cent of the injections of alum precipitated diphtheria toxoid and pertussis vaccine, mixed.

5. No infant so injected during the past five years with either mixture (plain or alum precipitated) is known to have contracted either disease.

CONCLUSIONS

A comparison of the immunity responses (negative Schick tests and 3 plus or 4 plus pertussis complement fixation tests) after three doses of mixed diphtheria toxoid and pertussis vaccine (plain or alum precipitated) shows that infants can be immunized successfully against the two diseases at the same time.

Although the immunity responses are somewhat higher with the alum precipitated mixture, using one third of the total number of *H. pertussis* bacilli, the occurrence of a sterile abscess following 2 per cent of the injections makes the plain mixture the product of choice.

Water Balance.—Water is a vitally important factor in nutrition. Measured by the urgency of demand and the promptness with which disaster follows failure of supply, it is of greater importance than the ordinary foodstuffs and is second only to oxygen. It is the vehicle which transports to the cells the nutritive elements and carries away the waste products of metabolism; it furnishes the medium in which all intracellular chemical changes take place.—McLester, James S.: *Nutrition and Diet in Health and Disease*, Philadelphia, W. B. Saunders Company, 1943.

THE TREATMENT OF FILARIASIS (WUCHERERIA BANCROFTI)

WITH LITHIUM ANTIMONY THIOMALATE

H. W. BROWN, M.D.

NEW YORK

Filaria infections and elephantiasis have not been of especial concern to American physicians despite the widespread distribution of this condition throughout the world. Only at Charleston, S. C., the endemic focus of the United States, has the disease been an immediate problem. The global nature of the present war, however, has exposed our armed forces to diseases not commonly present in the United States, and recent reports¹ indicate that our armed services are exposed to filaria infection and that numbers are becoming infected. Since this infection may have an incubation period up to a year or more and since it may lie quiescent for years, not only military but civilian doctors as well may have to cope with it in this country in returning service men.

Numerous drugs have been tried in the treatment of early filarial infections. Occasionally the treatment has resulted in a temporary decrease in the number of microfilariae circulating in the blood stream but the adult worms were not killed and they continued to produce microfilariae. Operative procedures late in the disease, when elephantiasis is present, frequently leave much to be desired and constitute an admission of the failure of early treatment.

Several of the few drugs that have a temporary effect on filarial infections contain antimony. The one on which the present study is based is lithium antimony thiomalate (Anthiomaline). It has the following structural formula:

It is supplied as a 6 per cent solution, 1 cc. containing 60 mg. of lithium antimony thiomalate or 10 ng. of antimony.

de Choisy² treated a patient who exhibited clinical manifestations of a *Loa loa* infection with lithium antimony thiomalate and reported improvement in his condition. Apparently no microfilaria counts were made on the patient's blood during or after treatment. A total of 35 cc. of lithium antimony thiomalate was given intramuscularly to this patient over a period of twenty-three days. Poynton³ injected lithium antimony thiomalate directly into enlarged lymph glands of patients harboring *Wuchereria bancrofti* or *Wuchereria malayi*. The attacks of fever were reported reduced

From the DeLamar Institute of Public Health, Columbia University College of Physicians and Surgeons

This study received financial support from the John and Mary R. Markle Foundation. I wish to acknowledge the interest of Mr. Archie Woods. Vice Admiral R. T. McIntire made it possible for me to spend a maximum of time in the tropics in this study through travel on the Naval Air Transport Service. Drs. Knud Knud Hansen, Mercurio Hoskins and Norman Thetford of the Virgin Islands Hospital Service offered me hospital facilities and the latter aided greatly in securing patients for treatment. The lithium antimony thiomalate (Anthiomaline) was furnished by Merck and Company, Rahway, N. J., and came from the Societe Parisienne d'expansion chimique specialisee.

in number and intensity in these patients. Chopra and Rao⁴ treated 7 filaria patients with lithium antimony thiomalate. They gave two intramuscular injections weekly, using up to a total of 30 cc. per patient. Only a temporary slight reduction in microfilariae was noted. Hawking⁵ likewise failed to secure a permanent microfilaria reduction in 10 *W. bancrofti* infected patients with lithium antimony thiomalate given intramuscularly. The total dosage employed by him varied from 7 cc. to 25 cc., which was given over a period of from twelve to forty-nine days.

Studies in the past four years by Brown, Brooks and Waletzky⁶ indicate that lithium antimony thiomalate is effective in the treatment of dogs infected with the filarid worm *Dirofilaria immitis*. Although the adult *Dirofilaria* lives free in the right cavity of the dog's heart and *Wuchereria bancrofti* of man lives in the lymphatic system, it was considered worth while to try lithium antimony thiomalate in human infections. Our dog studies suggested that somewhat larger total doses than had been tried by other workers might be needed to be effective in human infections. It is quite conceivable, however, that a drug which reaches sufficient concentrations in dog's blood to kill worms therein may not reach sufficiently high concentrations in the human lymph system to be lethal to worms harbored there.

Lithium antimony thiomalate has been used with some success in the treatment of lymphogranuloma venereum,⁷ trypanosomiasis,⁸ schistosomiasis⁹ and leishmaniasis,¹⁰ and the tolerated dosage has been approximately ascertained and toxicity for man studied.¹¹

Animal toxicity studies have been made by Launoy,¹² Laurens,¹³ Launoy and Lagodsky¹⁴ and myself (unpublished data). Additional toxicologic studies are also in progress in several laboratories.

METHODS

The 12 filaria patients treated during the summer of 1943 with lithium antimony thiomalate were all natives of St. Croix, Virgin Islands. They were

(Footnotes continued in next column)

already in the hospital for some other cause or were persons found to be microfilaria positive in a survey. Except for 1 patient who had greatly enlarged inguinal and femoral lymph glands and another with enlarged glands and scrotum, the only evidence of filaria infections of the remainder of the patients was microfilariae in the blood and a slight but definite general glandular enlargement with a history of recurrent lymphangitis. The patients were all given a complete physical examination prior to treatment in order to measure any later changes ascribable to the filaria infection or treatment. Blood counts and urine examinations were made before, during and after treatment.

A number of the patients remained in the hospital during the course of treatments, while others came in daily for their injection of lithium antimony thiomalate and continued their usual work and activity.

All injections of lithium antimony thiomalate were given into the gluteal muscles, alternating sides daily unless the patient complained of soreness on one side

Chart 1.—Effect of intramuscular injections of lithium antimony thiomalate on the microfilaria count

and asked for repeated injections into the other side. Usually a single daily injection was given on consecutive days unless prevented by poor cooperation of the patient or toxic manifestations of the drug. The adult dose of 3 cc. (180 mg.) was used, with adjusted smaller doses for children. On the first day of treatment a half-sized dose was given to ascertain sensitivity of the patients to the drug. In order to keep the drug level as constant as possible with a single daily dose the injections were given at regular twenty-four hour intervals.

The results of the therapy were measured by microfilaria counts on 0.1 cc. of blood after the method of Brown and Sheldon.¹⁵ Since the microfilariae exhibit a nocturnal periodicity, all specimens of blood were drawn from the cubital vein from 10 to 10:30 p. m.

Microfilaria counts on the blood of control persons not treated remained relatively constant during the six months that the treated patients were under observation.

RESULTS

The results of treatment are based almost entirely on microfilaria counts. In assaying the results it is

evident that a drug used in the treatment of filariasis may kill the microfilariae in the blood stream and not be fatal to the adult worms in the lymph system. In such an event microfilariae would disappear temporarily from the blood stream but again appear in the blood after treatment is discontinued, owing to repro-

Chart 2.—Effect of intramuscular injections of lithium antimony thiomalate on the microfilaria count.

duction by the adult worms. It is necessary, therefore, to examine the blood for several weeks or months after treatment has ceased to ascertain whether or not the adult worms, as well as the microfilariae, were killed. Microfilaria counts have now been made on the patients treated with lithium antimony thiomalate for from four and one-half to five months after the completion of treatment. Blood smears will also be examined at intervals for the next several months to give additional information of the status of the adult worms as judged by their ability to produce microfilariae.

Table 1 gives the dosage schedules of the various patients and also the microfilaria counts that were made at intervals on each patient.

CASE 1.—A woman aged 23, weighing 118 pounds (53.5 Kg.), exhibited slight general glandular enlargement. She was given 3 cc. of lithium antimony thiomalate on alternate days as suggested by workers using the drug in the treatment of lymphogranuloma venereum. She was given a total of 19.7 cc. (1.18 Gm.). No reduction was obtained in her microfilaria count by the completion of her treatment, but two months after treatment her microfilaria count had fallen from 86 to 47. Five months after the completion of treatment her count was 14. This patient had been delivered of a baby ten days before treatment with lithium antimony thiomalate was instituted. Microfilaria reduction was 89.3 per cent.

Chart 3.—Effect of intramuscular injections of lithium antimony thiomalate on the microfilaria count.

CASE 3.—A boy aged 14 years, weighing 85½ pounds (39 Kg.), exhibited slight general glandular enlargement. The microfilaria count was 455. He was given 1 cc. of lithium antimony thiomalate on the first day of treatment to test possible sensitivity to the drug. It was planned to give him 2 cc. daily. Approximately fifteen hours after the first injection he complained of pain in the right lower quadrant and experienced some difficulty in breathing. His pulse rate at this time was 128 and respiratory rate was 40 and temperature 100 F. Numerous rales and squeaks could be heard in his

chest. His breathing was eased by 0.5 cc. of epinephrine. His temperature rose to 101.6 F. On the following day the patient was again quite normal. He gave then a history of having what had been diagnosed as asthmatic attacks. Whether or not the attack was precipitated by the injection of lithium antimony thiomalate is unknown. Continued treatment was considered unwarranted at this time, however.

CASE 4.—A man aged 70, weighing 126 pounds (57 Kg.), had had enlarged inguinal lymph glands, the one on the left side the size of a hen's egg, and scrotum about three times normal size, since childhood. A daily dose of 3 cc. (180 mg.) of lithium antimony thiomalate was given (total 43.5 cc.). The pretreatment microfilaria count of 208 continued to drop and was 6 five months after the completion of treatment. The scrotal enlargement and greatly enlarged inguinal and femoral lymph glands did not appear to be affected by the treatment. On the 17th day of treatment the patient's temperature rose to 103 F. and he vomited a small quantity of clear yellow fluid. As the patient was hypertensive, treatment was discontinued. He experienced rises in temperature to 101 and 100 F. respectively on the two following days, with a subsequent return to normal. The microfilaria reduction was 97.1 per cent.

CASE 5.—A boy aged 11 years, weighing 68 pounds (31 Kg.), whose inguinal lymph nodes were slightly enlarged, was given a daily dose of lithium antimony thiomalate 1.5 or 2 cc. to a total of 48.5 cc. (2.91 Gm.). The pretreatment microfilaria

* Seven months after treatment.

count of 1,666 fell to 3 by the completion of treatment of twenty-seven injections. Four and one-half months after cessation of treatment the patient's microfilaria count was 3.

This patient had a daily rise of temperature to 99.5-100.2 F. on each of the seven last days of treatment. He vomited on the 8th day of treatment, and no drug was given the following day. Although he occasionally complained of a slight pain in his umbilical region, he did not vomit again although treatment was continued. The microfilaria reduction was 99.9 per cent.

CASE 9.—A youth aged 19, whose weight was 132 pounds (60 Kg.), presented slight general glandular enlargement. He was given a total of 55.5 cc. of lithium antimony thiomalate over a period of twenty days. By the completion of treatment his microfilaria count had risen to 42 from a pretreatment count of 12. Four months after the completion of treatment the microfilaria count was 12. The microfilaria reduction was 0 per cent.

CASE 10.—A man aged 28, weighing 124 pounds (56 Kg.), did not have microfilaria in his blood during the present study although hospital records indicate that they were present in 1941. In 1938 greatly enlarged right inguinal and femoral lymph glands were removed, and in 1941 those on the left side were removed. Lymph glands in these areas soon enlarged again and masses of them approximately 1 by 3 inches were present when treatment with lithium antimony thiomalate was begun. The patient complained that physical exercise resulted in considerable pain in the inguinal region. He was given 27 cc. (1.62 Gm.) of lithium antimony thiomalate over a period of twelve

days, treatment being somewhat irregular the last five days because of gastric distress and vomiting. The patient noted no improvement in inguinal pain on exercise during treatment. Five months later, however, he reported that the inguinal pain on exercise had greatly diminished and in fact had practically disappeared. There was no detectable change in the size of the inguinal and femoral lymph glands at this time.

CASE 17.—A youth aged 17 years, weighing 140 pounds (63.5 Kg.), presented slight glandular enlargement, especially in the inguinal region. This patient had the highest microfilaria count of the group, 2,324 to 0.1 cc. It is estimated that all of the patient's microfilariae if placed end to end would have stretched 11 miles, and their total volume was calculated as 48 cubic inches. He was given 3 cc. of lithium antimony thiomalate daily to a total of 49 cc. (2.94 Gm.). The patient's microfilaria count fell to 14 by the completion of treatment but rose to 137 ten days later. Four and one-half months after the completion of treatment his microfilaria count was 72. The microfilaria reduction was 96.9 per cent.

CASE 18.—A girl aged 16 years, weighing 86 pounds (39 Kg.), showed slight general glandular enlargement, especially noticeable in the epitrochlear regions. She was given a total of 35.5 cc. (2.13 Gm.) of lithium antimony thiomalate over a period of eighteen days. Her pretreatment microfilaria count of 1,100 fell to 25 by the end of treatment. Two weeks later the count had risen to 184, and four and one-half months after treatment it was 159. The patient vomited on the 13th, 15th and 16th days of treatment, so the dosage of the drug was decreased during this period and omitted on one day. The microfilaria reduction was 85.5 per cent.

CASE 21.—A girl aged 11 years, weighing 76 pounds (34.5 Kg.), showed slight general glandular enlargement, especially of the epitrochlear and inguinal lymph glands. She was given 2 cc. of lithium antimony thiomalate daily to a total dose of 32.0 cc. (1.92 Gm.). Her pretreatment microfilaria count dropped from 756 to 18 by the completion of treatment. During the next four and one-half months it gradually fell and became negative at the end of this time—a microfilaria reduction of 100 per cent.

CASE 22.—A woman aged 21, weighing 96 pounds (43.5 Kg.), showed slight general glandular enlargement, especially of the epitrochlear and inguinal lymph nodes. She was given a total of 15 cc. of lithium antimony thiomalate (0.9 Gm.) in seven days. Nine days after the last injection her count had fallen from 129 to 8 and four and one-half months later to 1, a microfilaria reduction of 99.3 per cent.

CASE 23.—A man aged 28, weighing 155 pounds (70 Kg.), showed general glandular enlargement, especially of the epitrochlear and inguinal lymph glands. This patient received the largest total amount of lithium antimony thiomalate, 76.5 cc. (4.59 Gm.) in daily consecutive doses over twenty-six days. He experienced no inconvenience from the treatment. His pretreatment microfilaria count of 159 fell to 1 by the 19th day of treatment. This microfilaria count of 1 persisted for two weeks after completion of treatment but fell to zero five months after treatment, a microfilaria reduction of 100 per cent.

CASE 24.—A boy aged 16 years, weighing 110 pounds (50 Kg.), showed general glandular enlargement. The epitrochlear and inguinal lymph glands were moderately enlarged. He was given a total of 29.5 cc. (1.77 Gm.) of lithium antimony thiomalate over a period of sixteen days. Late in the treatment it was impossible to maintain the daily dose of 2.5 cc. because of persistent vomiting. The patient's preliminary microfilaria count of 236 fell to 42 on the 9th day of treatment. In spite of continued, although irregular, treatment his microfilaria count rose and by two weeks after cessation of treatment was 134. From this point on the count fell to 33 on the 210th post-treatment day.

CASE 25.—A man aged 31, weighing 125 pounds (57 Kg.), showed slight general glandular enlargement, especially noticeable in the epitrochlear and inguinal regions. He was given daily injections of 3 cc. of lithium antimony thiomalate for ten days after the preliminary 1.5 cc. dose. By the end of this eleven day treatment period his microfilaria count had

dropped from 234 to 26. During the subsequent six days, however, treatment was omitted twice and decreased on one day because of vomiting and joint pains in the shoulder and elbow. He was treated therefore over a period of seventeen days, receiving a total of 42.5 cc. (2.55 Gm.). A week after the completion of treatment his microfilaria count had risen to 124. This count fell to 34 during the next four and one-half months, a microfilaria reduction of 85.5 per cent.

TOXICITY OF LITHIUM ANTIMONY THIOMALATE TO PATIENTS

Vomiting.—The most frequent toxic reaction, experienced by 40 per cent of the patients, was vomiting accompanied by epigastric pain. Vomiting occurred only after repeated injections, totaling from 0.780 to 1.89 Gm. of lithium antimony thiomalate. Vomiting occurred most frequently two to three hours after the injection, although it was sometimes delayed ten to twelve hours. In several instances the vomiting ceased although treatment was continued; usually, however, once vomiting began it continued as long as the full dose of the drug was continued. Pain in the epigastric region was complained of by the patients both before and after vomiting, and pain on pressure was noted in this area. To stop the vomiting the dose of the drug was reduced or treatment omitted entirely for one day. Ashkar¹⁶ and others have likewise reported vomiting after a total of 1.20 Gm. or more had been reached. Gobert⁹ suggests a two hour rest after antimony treatment to reduce vomiting. In the series reported here, however, vomiting occurred among those patients who were hospitalized as well as those who were treated in the outpatient department.

Local Reaction at the Site of Injection.—Gluteal reaction at the site of injection of lithium antimony thiomalate varied greatly from patient to patient. The majority of them experienced no inconvenience. Occasionally a patient would complain of soreness and ask for the next several injections to be given in the opposite side. One woman taking her injections in the outpatient department stopped treatment after seven injections totaling 0.9 Gm. of the drug, complaining of sore buttocks. Examination failed to reveal evidence of inflammation sufficient to warrant discontinuing treatment. Sites of former drug injections frequently could be palpated as firm intramuscular painless masses. There was no evidence of severe inflammation or abscess formation, and in general the reaction at the site of injection was of little moment. Grenierboley¹⁷ and Moulinard¹⁸ stress the local and general tolerance to intramuscular injections of lithium antimony thiomalate, while Chopra and Rao⁴ report that it caused severe reaction with pain and swelling at the site of injection. The latter were using doses up to 5 cc., which may explain the severe reactions. The maximum dose used in the series reported here was 3 cc.

Fever.—Two patients experienced fever near the end of their series of treatment. One patient's temperature rose suddenly to 103 F. after 2.61 Gm. of lithium antimony thiomalate and fell to normal over a period of three days when the drug was discontinued. The other patient had a low grade fever of 99.5 to 100.2 F. during the last seven days of treatment. Sézary and

Bolger¹⁹ and others have likewise noted fever, usually during the last days of a series of injections.

Arthritis.—Although other workers²⁰ report localized pains of arthritic character as the most frequent toxic reaction of lithium antimony thiomalate therapy, it was experienced by only 1 of the patients in this series. After 1.71 Gm. of drug 1 patient (25), weighing 125 pounds (57 Kg.), noticed pain in his right shoulder area. Treatment was continued, and on the following day pain was noted also in his left shoulder. As the treatment continued the pain extended down the flexor surfaces of his arms to his elbows and became so severe that he moved his arms only with great pain. Treatment was suspended for a day with decided improvement of his arms and shoulder. The pain seemed to be localized in the joints, in the tendinous insertions and even in the muscles. The areas of the joint were very sensitive to pressure. There was no alteration in reflexes or edema.

Urine.—Intravenous phenolsulfonphthalein tests were done on the patients to ascertain kidney function before treatment. Only 1 patient (25) exhibited an

TABLE 2.—Blood Picture Before and After Treatment with Lithium Antimony Thiomalate

5.....	3,650,000	70%	8,400
18.....	3,000,000	68%	8,600
21.....	2,440,000	60%	6,200
Four to Five Months After Treatment			
4.....	3,400,000	70%	6,600
5.....	3,630,000	72%	9,200
18.....	2,980,000	65%	8,400
21.....	3,420,000	70%	7,000

excretion rate below the so-called normal. This patient's fifteen minute excretion was 8 per cent and one hour excretion 30 per cent. The patient tolerated the early portion of the treatment very well, but late in the treatment series he experienced the only arthritic disturbance encountered and also vomited.

Examinations of the various patients' urine (sugar, albumin, reaction, casts and blood cells) were made at intervals during treatment and there was no evidence of renal damage. Patient 5 had a trace of albumin in the urine before starting treatment. A trace of albumin was found in the urine on the 10th day of treatment after a total of 24.5 cc. of lithium antimony thiomalate had been administered. The urine was free from albumin thereafter. Patient 23 showed a trace of albumin in the urine after 37.5 cc. of lithium antimony thiomalate, but another specimen examined six hours later was albumin free. On the 20th day of treatment after 58.5 cc. of the drug he also had a trace of albumin in the urine.

Rashes.—Six of 12 patients experienced transitory itching rashes after a number of injections of the drug. In 3 instances the rash was on the lateral aspects of

the fingers and thumbs and consisted of small raised papules 1 to 2 mm. in diameter. One patient had a similar rash on his face, especially his forehead, as well as his hands. Another patient had a punctate red rash on the chest and the flexor surfaces of his arms, and 1 patient had a similar rash on his chest and abdomen only. The rashes were not severe and usually remained static or disappeared even though treatment was continued. There is some question as to the exact etiology of the rashes and the relation of the lithium antimony thiomalate to them.

Blood.—Sézary and Bolger¹⁹ believe that prolonged administration of lithium antimony thiomalate seemed to cause a certain degree of anemia. On the other hand, Ashkar¹⁶ observed no change in the blood picture "except for the eosinophilia that usually occurs with the other antimony compounds." Brooks²¹ using dogs, followed the blood picture after an intravenous injection of 4 cc. of anthiomaline with the following results:

In both dogs used for this study there was a decrease of more than 50 per cent in the total white blood cell count within fifteen minutes after the drug was administered. Following this there was a rapid rise to 17,000 in 1 dog and 19,000 in the other. This maximum degree of leukocytosis was reached in approximately twelve hours in both cases. Over a period of ninety-six hours the total counts gradually decreased again to what was considered normal for these individual dogs. The red blood cell counts showed a brief rise following the injection of anthiomaline, after which there was a gradual decrease up to twenty hours. By the end of ninety-six hours the counts were again normal.

Launoy and Lagodsky,²² using lithium antimony thiomalate in rabbits intravenously, conclude that four to five injections over twenty-four to thirty-five days produced only a slight transient anemia.

The blood of 4 patients in the series reported here was examined before treatment and four weeks and four to five months after treatment (table 2). The red blood cell count of patient 18 was approximately 500,000 cells lower four weeks and four months after treatment, although her hemoglobin remained unchanged. Patient 21 had a drop of approximately 1,000,000 red cells four weeks after treatment but returned to the pretreatment level by four months after treatment. The variations in white blood cell counts were probably all within normal limits.

It has been suggested by O'Connor²² that the pathologic changes in filaria infected persons result from the host reaction to the dead adult worms. The results of any therapy that has as its purpose the killing of the adult worms and microfilariae should therefore be followed for a considerable period to ascertain the patient's reaction to the death of both the adult worms if this occurs and the death of the microfilariae if their decrease in number is due to lethal action of the drug rather than to a normal rate of death which is not followed by normal reproduction by adults. It is planned to follow the patients treated with lithium antimony thiomalate for several years to ascertain whether or not the death of their parasites affected them adversely.

Four and one-half to five months after the completion of treatment the patients were given a physical reexamination, and a medical history was taken of this period. None of the patients gave any evidence of a reaction attributable to death of either adult worms

or microfilariae. There were no changes in the size of their glands and no evidence of inflammation or edema. Likewise none of the patients gave a history of inflammation, enlargement of glands or edema during the four to five months following treatment. If it is true that dead worms cause the pathologic changes, the large numbers of microfilariae (23,240 per cubic centimeter in patient 17) and adult worms should in time result in inflammatory reactions. On the other hand, tremendous numbers of microfilariae must die every day and be taken care of by the host in the average untreated case of filariasis, for if the length of life of a microfilaria is sixty to seventy days,²³ then one sixtieth to one seventieth must die each day and be replaced. Patient 17 had an estimated 100,000,000 microfilariae in his blood stream; hence approximately 1½ million would die each day. This continued destruction of microfilariae by the host may partially desensitize him to the foreign protein of the worms.

The patient's blood will also be followed at intervals for several years after treatment. If their blood stream remains free from microfilariae for months it is strong evidence that the adult worms are dead and were killed by the lithium antimony thiomalate. On the other hand, if microfilariae begin to appear twelve to fifteen months after treatment it is possible that reinfection has taken place since treatment, for this is approximately the length of time for a new infection to produce microfilariae.

COMMENT

The results of treatment with lithium antimony thiomalate of *Wuchereria bancrofti* infected persons strongly suggests that the drug is lethal not only to the microfilariae but also to the adult worms as well and that from 85 to 100 per cent of the worms are killed by one series of the drug. It is possible, of course, that the microfilariae circulating in the blood are more delicate than the adults and are more readily killed. Likewise a higher concentration of the drug may reach the microfilariae in the blood stream than reaches the adults in the lymphatics. Experience indicates that a drug may kill the microfilariae and temporarily sterilize the adult female so that the production of microfilariae is temporarily inhibited. It is essential, therefore, that the patient's blood be repeatedly examined for microfilariae over a considerable period after the completion of the treatment. The patients treated with lithium antimony thiomalate have been examined for microfilariae for from four and one-half to five months after the completion of treatment to determine the effect of the drug on the adult worms. It is considered unlikely that the adult worms that were injured to the extent that they did not produce microfilariae after four and one-half to five months are still alive.

Treatment with lithium antimony thiomalate usually resulted in decided reduction in microfilaria counts after a total of 15 to 20 cc. of the drug. Although treatment was continued there was an additional though slower reduction in microfilaria count. This suggests that the microfilariae may vary in susceptibility to lithium antimony thiomalate and that the resistant ones were killed only after a longer exposure to the drug. It may also mean that the adult worms differ in the rapidity with which they were killed owing either to individual variation in resistance or to their localization

in the host. The initial sudden drop in microfilariae then may have been due to their elimination from the blood stream by the direct action of the drug. The adults, presumably more resistant to the effects of the drug and more slowly killed, continued to supply the blood stream with fewer and fewer microfilariae.

The continued persistence of microfilariae in the blood four to five months after treatment suggests that adult worms are still present, possibly protected in a fibrosed lymph gland from lethal concentrations of the drug. Our present knowledge indicates that microfilariae persist in the blood approximately ten weeks. It is doubtful, therefore, if the continued persistence of microfilariae could have been possible for five months without the presence of the adults.

The daily dosage of lithium antimony thiomalate per kilogram weight of the patient varied from 0.00155 Gm. to 0.00313 Gm. Likewise the total drug administered varied from 0.0217 Gm. to 0.0831 Gm. per kilogram weight of patient. It is impossible, however, in such a small series to correlate the drug dosage with effectiveness of treatment. It is known from the work of Chopra that there is great individual variation in the excretion rate of antimony by man. Hence given the same dosage, patients may vary in the actual antimony blood levels attained. Until a satisfactory method for the determination of antimony blood levels is available, the size and rate of lithium antimony thiomalate injections will be more or less empirical. Presumably the best therapeutic regimen would be one that maintained a high blood and tissue antimony concentration. This is predicated on the basis that antimony is the active element of the drug. On the other hand, there may be considerable variation in therapeutic effect between cases even though the blood antimony is the same, for there may be a decided difference in the location of the adult worms and the penetrability of their environment by the drug.

The lack of severe acute and chronic toxicity of lithium antimony thiomalate for man suggests, at least from present data, that continued carefully supervised therapeutic trial of this drug in filariasis is warranted.

It is recognized that lithium antimony thiomalate is not the ideal drug for the treatment of filariasis, as it does not kill all of the worms of all the patients and because of its toxicity for man. On the other hand, it may be possible to improve on its effectiveness by adjusting the size of doses and by giving several series of treatments. This problem is under study. On the other hand, if lithium antimony thiomalate is not used, no other therapeutic agent is available that offers any promise of cure.

The treatment of filariasis after the patient becomes microfilaria positive may be analogous to the treatment of syphilis after the patient exhibits a positive serologic reaction. In syphilis it is much more satisfactory to start treatment earlier on the basis of a positive dark field examination. Likewise in filariasis during the year or two between infection and becoming microfilaria positive the host reaction about the worm and growth of the worm may make it much more difficult to eliminate the infection. It might be highly advantageous therefore to treat a filaria infection as early as a diagnosis can be made. A clinical²⁴ and serologic²⁵ diagno-

sis of filariasis sometimes may be made within three to five months after infection, i. e., one to two years before microfilariae appear in the blood, and it is suggested that a cure of these early cases may be successful; as the worm is immature, smaller and presumably not as robust as the full grown adult. Likewise tissue reactions about the young worm may be at a minimum and permit access of the drug to them in higher concentrations. A group of these early clinical cases that are microfilaria negative are now under treatment and will be reported later.

SUMMARY

1. Lithium antimony thiomalate, a compound given intramuscularly to a series of filaria infected patients, reduced their microfilaria count 85 to 100 per cent. This reduction was maintained for four to five months after the completion of treatment and means presumably that a corresponding number of the adult worms were killed. One patient failed to respond to treatment, and there was no reduction in his microfilaria count.

2. No reduction in size of enlarged lymph glands or one enlarged scrotum could be detected four to five months after the completion of treatment. One patient noted a pronounced improvement in his inguinal distress on exercise following treatment.

3. The patients' history and physical examination failed to reveal any pathologic changes due to the death of the adult worms or microfilariae.

4. The toxic manifestations due to lithium antimony thiomalate of vomiting, joint pain, slight fever and rash are not considered sufficient to preclude its continued trial in filariasis.

COMPLICATIONS FOLLOWING ARTERIOGRAPHY OF PERIPHERAL VESSELS

FREDERICK B. WAGNER JR., M.D.

PHILADELPHIA

Arteriography of nearly all the main arteries of the body, including the carotid, pulmonary and abdominal aorta, has been successfully performed. The latter vessels require special technics, but the procedure for those of the extremities, though exacting, is fairly simple. The study permits accurate visualization of the direction of the course of the arteries, the width of the lumen and the shape of the inner wall. Thus arteriography demonstrates the degree and level of arterial obstruction in the severe tissue nutritional disturbances of arteriosclerotic occlusion, embolism, Buerger's disease and large vessel trauma; the amount of collateral circulation; the site of arteriovenous aneurysms, and in simple arterial aneurysm the position of the sac and its patency or obstruction by thrombosis. It has therefore been employed in these conditions when in spite of the clinical observations, aided by oscillometry, skin surface temperature readings, histamine wheal tests and so on, finer delineation of the pathologic changes is desired because of the continued progress of the disease. Furthermore, as stressed by Inclan¹ and reenphasized by Shallow,² arteriography should be

performed in preference to specimen and punch biopsy in the early diagnosis of bone tumors, since the latter procedure in the case of malignant lesions may spread the disease into the very rich venous circulation. In addition; by arteriography one can determine the exact limits of the bone lesion, distinguish the benign and the inflammatory from the malignant, and denote the stage of the malignant growth.

Although arteriography is not universally practiced at present, the growing importance of this study in the more accurate diagnosis of arterial lesions and the earlier diagnosis of bone cancer encourages its more widespread employment. At the same time the procedure is not without danger, and for this reason the report of an untoward reaction is cited and in addition the various complications both local and systemic following peripheral arteriography are discussed:

REPORT OF CASE

History.—D. L., a Negro girl aged 14 months, was admitted to the Jefferson Medical College Hospital on Nov. 18, 1942 because of swellings just below the right elbow, over the lower third of the right thigh and on the left forehead, first noted several days after birth.

The swelling of the elbow gradually increased, and about two weeks prior to admission the infant developed fever. At that time the swelling was incised and drained in the accident ward and about an ounce of pus (positive for *Staphylococcus aureus*) obtained. The wound did not heal well, and the infant was admitted to the hospital.

Except for the recent acute episode, the infant's general health had been good and growth was normal.

The mother had died two months previously from tuberculosis.

Physical Examination.—The infant was well developed and weighed 18 pounds 4 ounces (8,278 Gm.). The temperature was 102 F., the pulse rate 150 and the respiratory rate 54. At the upper end of the right ulna was a tender, indurated area, 4 cm. in diameter, from which

Fig. 1.—Arteriogram in case of tuberculous osteomyelitis of proximal end of right ulna in an infant aged 14 months.

there was slight drainage through a small recent incision. In addition there was a firm, round, fixed, nontender, semifluctuant mass 2 cm. in diameter on the left forehead as well as a similar mass 3 cm. in diameter on the anterior aspect of the lower third of the right thigh.

Laboratory Studies.—Hemoglobin was 61 per cent, red cells numbered 3,700,000 and white cells 22,800, with neutrophils 65 per cent (15 per cent young forms), lymphocytes 22 per cent and monocytes 13 per cent. Urinalysis revealed slight albuminuria. The blood Wassermann and Kahn reactions were negative. Repeated smears and cultures of pus from the elbow lesion were positive for *Staphylococcus aureus* but negative for acid fast bacilli. The tuberculin test was strongly positive following the first test dose.

X-ray examination revealed an expansile lesion somewhat cystic in nature, with numerous layers of periosteal new bone formation, involving the upper third of the right ulna, interpreted as either low grade osteomyelitis or a Ewing's tumor. The remainder of the skeleton was normal. The chest films revealed a widening of the superior mediastinum with densities

2. Shallow, T. A.; Raker, N., and Fry, K.: Primary Malignant Tumors of Bone with Special Reference to Osteogenic Sarcoma, *J. Internat. Coll. Surgeons* 6: 89, 1943.

extending into both lung fields and displacement of the trachea to the right. The lung fields were otherwise clear, and the heart appeared normal.

Since by clinical and x-ray examination it was impossible with certainty to distinguish between a purely inflammatory lesion and a neoplastic one, and since it was desirable to avoid a biopsy, an arteriography was performed on Feb. 27, 1943 under open drop ether anesthesia. The brachial artery was exposed surgically at the lower third of the arm and 7 cc. of neo-iopax injected following temporary occlusion just above the site of the puncture. The films obtained (fig 1) showed an increase in the number of vessels around the upper end of the ulna, with dilatation and a fuzzy outline. Contrast material was seen in the large spaces within the bone structure. These findings were interpreted as representative of a low grade osteomyelitis of either a pyogenic or tuberculous origin.

About three minutes after the injection it was noted that the extremity was colder than the corresponding opposite member.

During the next six months the arm was immobilized in a cast. The ulcers (fig. 2c) as well as the bone lesion gradually healed during this time, and complete function of the extremity returned. Figure 2d shows the appearance of the forearm and hand eight months after injection, at which time there was still absence of the radial pulse.

The nodule of the forehead was excised on April 28 and reported by the pathologist to be a tuberculous lesion. The lesion on the thigh disappeared over a period of several months, and the patient was discharged on September 7. On November 28 she was readmitted with severe gastroenteritis and died of disseminated tuberculosis on December 12. Permission for autopsy was unobtainable.

COMMENT

It seems likely that the complication in this case began with vasoconstriction resulting from the irritating effect of the contrast material. In view of the persistent absence of the radial pulse, the vasomotor

Fig 2—Appearance of forearm and hand following arteriography complicated by arteriospasm and thrombosis (a) Temporary Volkmann's contracture forty eight hours later, (b) ulceration of skin with edema subsiding five days after injection, (c) ulcers almost healed six months later; (d) complete healing eight months after injection. Radial pulse still absent

The radial pulse, which previously had been of good quality, disappeared, and cyanosis of the finger tips was noted. The infant was returned to the ward and treatment begun immediately, consisting of elevation of the extremity, warm compresses, and papaverine for antispasmodic effect. Within forty-eight hours the forearm and hand became considerably swollen and diffusely tender. The fingers were partially flexed, and there were no spontaneous movements of the fingers or hand. Numerous ecchymotic areas varying in size from several millimeters to 2 cm. in diameter appeared on the fingers, dorsum of the hand and forearm. At this time the appearance of the arm resembled that seen in ischemic paralysis or Volkmann's contracture (fig. 2a). Some of the ecchymotic areas resorbed, while blisters filled with serosanguineous fluid appeared over the others and subsequently broke down, forming superficial punched-out ulcers (fig. 2b). At this time, five days after injection, the edema began to subside, and feeble attempts at spontaneous movements of the fingers were noted. The temperature, which before arteriography had ranged between normal and 102 F, continued at 103-104 F. for six days following injection and then gradually subsided.

reaction must have been followed by thrombosis of the brachial artery, but collateral circulation was sufficient to prevent gangrene.

Complications both local and systemic following arteriography are most prone to occur at the two extremes of life, because in infancy and childhood the vessels are particularly susceptible to spasm, those of the upper extremity more so than the lower, and since in old age the incidence of arteriosclerotic occlusion is increased, with collateral circulation poor. In the etiology both mechanical and chemical factors play a role. Trauma to the artery as a result of puncture by the needle and the force of injection by arterial distention may in themselves provoke reflex vasoconstriction. The ideal contrast solution should be nontoxic, nonirritating, isotonic with the concentration of the blood and excreted promptly, but these criteria have not been completely satisfied by either thorotrast or the organic iodine compounds.

LOCAL REACTIONS

Hematomas.—A hematoma may follow the arterial puncture and in some cases an inadvertent venipuncture when the percutaneous route is used. It usually resorbs promptly following moist applications and external heat. Demel³ states that in arteriosclerosis in 1 out of 300 cases there may be bleeding from the artery, readily controlled with a suture through the adventitia. Dos Santos,⁴ among 1,500 arterial punctures, had only 1 case of persistent bleeding, necessitating ligation of an atheromatous femoral artery, and the patient recovered without gangrene.

Extravasations.—Displacement of the needle before or during injection may occur, with infiltration of the adventitia or periarterial tissue with contrast material. In 411 arteriographies with use of thorotrast dos Santos⁴ had only 8 extravasations (less than 2 per cent). Dimtza and Jaeger⁵ among 70 percutaneous arterial injections had 6 extravasations, but they were not followed by serious consequences except nausea and fever. The material may accumulate locally around the vessel and eventually produce an inflammatory reaction. Moist applications and external heat encourage resorption, which is usually slow and accompanied by induration and fibrosis but no permanent untoward effects. Less frequently the inflammatory reaction may proceed to actual suppuration, in which instance incision and drainage of a fluctuant mass may be required. Occasionally the contrast material may extravasate along the course of the vessel in linear fashion (cases of Garraud,⁶ dos Santos⁴ and Desplas and Reboul⁷). These cases usually respond well to the conservative measures already mentioned. Thorotrast may diffuse by way of the lymphatics and slowly form a mass some distance from the original site of injection. Thus, dos Santos⁴ reports the development of a suppurative mass in the iliac fossa two years after femoral arteriography with thorotrast complicated by extravasation of the contrast material.

Severe Vasomotor Reactions.—Among the serious complications are severe immediate vasospastic reactions in the injected limb. In almost all instances, as in the present case report, these have followed the use of organic iodine compounds rather than thorotrast. Dos Santos⁴ in 129 arteriographies with organic iodine compounds had 6 cases in which gangrene was aggravated, in contrast to no vasomotor reactions in more than 300 with thorotrast. The reaction is first manifested by severe pain in the limb and blanching followed by venous stasis. After several hours there appear scattered violet plaques, some of which may become confluent, in the skin distal to the point of injection, due to cutaneous and subcutaneous hemorrhages. Later they may appear proximal to the point of injection, as in a case of Lambret⁸ and 1 of Leclerc⁹ in which plaques appeared in the skin of the lower abdominal wall following femoral arteriography. Motor paralysis may occur, skin and tendon reflexes may be abolished

and anesthesia may be present distal to the zone of injection. The pain usually subsides in two or three days. The cyanotic plaques slowly resorb, progressively passing through the various colors of a hematoma, and blisters may appear over some of them. Movement and sensitivity gradually return, and in a week to ten days the limb may become normal. In other cases a preexisting gangrene may be aggravated.

In a few instances the puncture site has been surgically explored. The muscles are engorged with dark blood which flows readily from the veins, but blood does not spurt from the arteries. On exposing the area of the puncture, there is no hematoma and the orifice of the puncture is not identifiable. According to Leveuf,¹⁰ the artery does not pulsate and aspiration with a needle fails to obtain blood. On opening the artery a soft clot is found which does not prevent passage of the needle into the lumen of the vessel. Histologically the skin epithelium is intact. The capillaries of the subcutaneous tissue are dilated and congested, and there is an infiltration of leukocytes, chiefly eosinophils. There is no lesion of the arterial wall in the vicinity of the site of the puncture, and the orifice cannot be found. The arterial lumen often contains a recent thrombus undergoing rapid organization (Leveuf;¹⁰ Sèneque and Benoit¹¹).

The occurrence of these severe local reactions may be reduced by a more careful selection of cases for arteriography, the employment of a painstaking technic of puncture and injection, and the proper choice of contrast material. Thus, in young children, in patients with preexisting vasospastic arterial disease or in cases of organic occlusion with poor collateral circulation the risk of superadded vasospasm must be avoided, and therefore the use of the organic iodine compounds for these patients is contraindicated. The use of thorotrast, although relatively safer for these types of cases, is not without danger, since Lambret⁸ has reported a case of aggravation of gangrene following the injection of this substance, with death nine days later. Definite treatment of the complication, once it has occurred, consists in the use of antispasmodic and vasodilator drugs and the mechanical measures commonly employed against the ischemia of peripheral vascular disease, such as Buerger's exercises, oscillating bed and intermittent venous occlusion apparatus. In some instances the development or aggravation of gangrene may require amputation (case of Leveuf¹⁰).

SYSTEMIC REACTIONS

Severe systemic reactions may occur following arteriography both with thorotrast and with the organic iodine compounds. Thus, dos Santos⁴ has reported a case in which following the use of thorotrast there occurred hematemeses and a pronounced anemia with decreased coagulability of the blood but with recovery following transfusions. Arteriography was performed with thorotrast in the case of an infant because of a Volkmann's contracture, and death occurred the same evening following several arrests of respiration (Wertheimer and Frieh¹²). Some reports have emphasized the tendency of thorotrast to produce necrosis and neoplastic changes in tissues in which it is contained, particularly the cells of the reticuloendothelial system

in the liver and spleen, in which its radioactivity may be maintained for ten to fifteen years; but just how much damage may result in human beings has not been established, and to date no effects of this nature have been described following the small doses used for arteriography of the peripheral vessels.

Systemic reactions following the injection of organic iodine compounds consist of flushing of the skin with a feeling of warmth, erythematous eruptions, nausea, vomiting, cyanosis, respiratory distress and fall in blood pressure. These reactions usually subside within a few minutes to an hour, but the skin eruptions may persist for several days. Death may occur as an immediate reaction as the result of hypersensitivity or idiosyncrasy to the injected material, or else delayed, in which instance it is thought to be due mainly to preexisting extensive renal damage. Pendergrass and his co-workers¹³ conducted a survey of deaths following the administration of organic iodine compounds as contrast mediums in 661,800 examinations, mostly urographic, and collected, in addition to the 11 previously reported cases, 26, representing an incidence of 0.0039 per cent. The latter figure, although not strictly representative for arteriography, gives some idea of the risk of fatality associated with the injection of these substances into the blood stream.

A decrease in the number of fatalities can be achieved by a strict adherence to the contraindications for use of the various contrast mediums and by prompt treatment when systemic reactions unexpectedly occur. In New and Nonofficial Remedies for 1943¹⁴ the contraindications listed for contrast mediums are severe liver disorders, nephritis and uremia. It is further advised in this issue that they be employed with caution in pulmonary tuberculosis and hyperthyroidism. Because of the reported fatalities due to hypersensitivity, it is essential that a careful allergy history be taken as well as the performance of one of the standard sensitivity tests for the contrast material such as the patch, intradermal, conjunctival, mouth or intravenous test. Patients with suspected kidney disease should have renal function tests performed and arteriography withheld on those with significant impairment. As it is now well known that even these precautions and tests do not warn adequately in all cases against sensitivity and toxic reactions, it is important to have facilities available for the immediate intravenous administration of epinephrine (1:1,000), caffeine and sodium benzoate, nikethamide or calcium gluconate.

CONCLUSIONS

Arteriography of the peripheral vessels is of value in the accurate diagnosis of arterial lesions and the early diagnosis of bone cancer but is not without danger.

The risk of complications does not warrant the abandonment of arteriography as a diagnostic aid but rather should keep one alert to minimize the danger by a proper selection of cases, careful choice of contrast material associated with the taking of an allergy history and the performance of a standard sensitivity test, painstaking technic and preparedness for prompt treatment if the necessity arises.

STUDIES ON HUMAN SCHISTOSOMA MANSONI INFECTIONS

I. PROCTOSCOPIC PICTURE IN ASYMPTOMATIC SCHISTOSOMIASIS MANSONI INFECTIONS

LIEUTENANT COLONEL Z. T. BERCOVITZ

CAPTAIN R. RODRIGUEZ-MOLINA

CAPTAIN DUDLEY W. HARGRAVE

CAPTAIN J. D. DICKIE

AND

LIEUTENANT CHARLES E. GREEN

MEDICAL CORPS, ARMY OF THE UNITED STATES

In the physical processing of Puerto Rican male inductees for Selective Service, a routine stool examination has been required by the Antilles Department. As a result of this type of examination, approximately 10 per cent¹ of otherwise healthy males were found positive for the ova of *Schistosoma mansoni*. A report of the Survey by Antilles Department Laboratory will appear shortly as part of this series of studies. In the light of this fact it was decided to carry on a proctologic study of a group of ova positive applicants, in an effort to ascertain what pathologic changes, if any, were demonstrable in the rectal mucosa of the hosts.

Proctoscopic Observations

	Number	Per Cent
Normal mucosa	61	39.3
Normal mucosa with ulceration.....	75	48.5
Normal mucosa with polyps.....	2	1.3
Normal mucosa with hemorrhagic areas	13	8.3
Atrophic mucosa	2	1.3
Inflammation	2	1.3

The finding of changes in the rectal mucosa in 60.7 per cent of the 155 persons examined is in keeping with our understanding of the pathologic changes which take place in this infection and with our present knowledge of the life history of the infecting parasite.

METHODS AND RESULTS

These young men were hospitalized in the gastrointestinal ward, given a low tepid water enema and then examined proctoscopically. External and digital examinations were entirely negative and failed to reveal any evidence of hemorrhoids, eversion of the rectum, tumor masses or other pathologic changes. The proctoscope was passed under direct vision up to the rectosigmoid fold in all patients and for 4 cm. to 5 cm. within the sigmoid colon in about one half of the patients.

The mucosa was entirely normal in 61 persons, or 39.3 per cent of the examinations. In 94 persons (60.7 per cent) proctoscopy revealed ulcerations which have been found to be characteristic of infections with *S. mansoni*.

This is the first of a series of studies carried on by members of the Medical Corps, Antilles Department.

Lieutenant Colonel Bercovitz was formerly assistant clinical professor of medicine, New York Post Graduate Medical School, Columbia University, New York, on leave of absence.

Captain Rodriguez-Molina was formerly associate professor of tropical medicine, Puerto Rico School of Tropical Medicine, San Juan, Puerto Rico, on leave of absence.

This study was made at the suggestion of Col. Clyde C. Johnston, Department Surgeon, Antilles Department.

1. Dammin, G. J. and Weller, T. H. Personal communication to the authors.

The ulcerations were single pin point, located just below the rectosigmoid fold in 12.7 per cent (12 examinations), the remainder of the mucosa being entirely normal. In 10 other examinations (10.6 per cent) there were single linear ulcers which appeared as a crack in the otherwise healthy mucosa. These single linear ulcerations were up to 3 mm. in length.

The ulcerations were multiple in 77 of the examinations (81.6 per cent) and included both pin point as well as linear ulcerations. When pin point or oval they were up to 1 to 2 mm. in diameter and as much as 3 mm. in length when linear.

There was sharp demarcation of the ulcerated area from the surrounding normal mucosa. There was no zone of inflammation, no crater or ragged edges and no exudate that could be seen. The ulceration appeared as a noninflammatory spot giving the impression that something had extruded through the mucosa into the lumen of the bowel. When examined with a proctoscope there was a definite break in continuity of the mucosa, and free blood was seen to ooze from these areas. When this was wiped off, the noninflammatory ulcerations

tissues of the gut provokes a dense cellular infiltration, leading to a thickening of the bowel wall and an excess of mucus production. These lesions gradually enlarge, so that on the mucosal surface localized areas of hyperemic tissues develop into abscesses, which break through the mucosa to the surface, causing minute hemorrhages with the discharge of bloody mucus, pus and eggs. These minute ulcers frequently become quite extensive, particularly if secondary infection develops."

In the sixth of a series of studies on schistosomiasis *mansoni* Koppisch⁴ describes the morbid anatomy of schistosomiasis as found in 147 autopsies on Puerto Rican patients. Depending on the degree of severity of infection and the duration of the disease, he grouped the cases according to whether the infection was minimal, moderate, severe, healed or doubtful. He found that 64.6 per cent of his cases were minimal and had no clearcut clinical manifestations of schistosomiasis or gross pathologic changes at autopsy which were of diagnostic import.

The group of moderately advanced cases comprised 14.2 per cent, and he noted that schistosomiasis was

Reproductions from kodachromes made through the proctoscope, showing ulcerations at the bifurcations of the capillaries superimposed on the vessels and outlining the blood vascular pattern

tion was visualized. In those instances which were reexamined the following day it was noted that many of the ulcerations seen on the previous day had disappeared.

The ulcerations were nearly always either at the bifurcation of the capillaries or lying directly on them. This relationship of the ulcerations to the blood vessels of the rectum was so constant that a definite relationship was established. It should be noted that the capillaries and in some instances the venules were readily visualized. In some instances in which the ulcerations were numerous they could be seen following the course of the capillaries, outlining them in a definite pattern.

The ulcerations were located below the rectosigmoid fold. In only 1 instance was there a suggestive area on the fold. Polyps were seen in but 2 cases, one being 3 to 4 mm. long, the other about 1 cm. and pedunculated.

COMMENT

The finding of ulcerations as described is in accord with the pathologic picture as given by Koppisch,² who has also described the method of extrusion of the ova of *S. mansoni* through the mucosa into the lumen of the bowel. This picture has been summarized by Faust,³ who states that "the presence of eggs in the

inapparent clinically. Severe cases made up only 8.1 per cent of the number, and this group is representative of the last stages of the disease. The mucosal venules and submucosal veins were dilated and engorged with blood in many of the severe cases even in the absence of acute colitis.

The present conception of schistosomiasis *mansoni* infection as just described in human beings has been that of bloody diarrhea with mucus, followed in the untreated cases by involvement of the liver and spleen in the so-called visceral schistosomiasis. Actually this picture in its various modifications takes place in only 4 per cent of the cases, as shown by Koppisch,⁴ and fails to account for the fact that ulcerations in the rectal mucosa were found in 60.7 per cent of 155 otherwise perfectly healthy young Puerto Rican men in whom the ova of *S. mansoni* had been found on fecal examinations.

It is evident from this study that the finding of ova of *Schistosoma mansoni* in the stools is equivalent in at least 60.7 per cent of the cases to the finding of ulcerations in the bowel mucosa and definitely indicates infection with this parasite. There is no such condition as a healthy carrier of *S. mansoni*, and the

3. Faust, E. C.: *Human Helminthology*, Philadelphia, Lea & Febiger, 1939.

4. Koppisch, E.: *Studies on Schistosomiasis Mansoni in Puerto Rico. VI. Morbid Anatomy of the Disease as Found in Puerto Ricans*, Puerto Rico J. Pub. Health & Trop. Med. 10:395 (March) 1941.

presence of ova is equivalent to the diagnosis of schistosomiasis.

As a result therefore of these studies, careful examinations of the feces must be made of all persons who have been living in an area suspected of being infected with *S. mansoni* even though those persons do not complain of any symptoms or present signs suggestive of schistosomiasis.

SUMMARY

Ulcerations of the rectal mucosa were found in 60.7 per cent of 155 otherwise healthy Puerto Rican young men in whom ova of *S. mansoni* were discovered on routine fecal examinations. The bowel mucosa was generally soft, velvety and pale pink, with single or multiple ulcerations which were either pin point or linear. There was sharp demarcation of the ulcerated area from the surrounding normal mucosa and there was no zone of inflammation, no crater or ragged edges and no exudate. The ulceration was a noninflammatory break in the continuity through which oozed a small amount of blood. The ulcerations were at the bifurcation of the capillaries or lying directly on them. This relationship of the ulceration to the blood vessels was so constant that a definite relationship could be established. When the ulcerations were numerous, they outlined the pattern of the capillaries. The ulcerations were below the rectosigmoid fold. Polyps were seen in only 2 instances.

A review of the present concepts of schistosomiasis infections as pointed out by Faust, Strong, Koppisch and others in clinical-pathologic studies fails to account for this larger group of individuals who are infected with this parasite and have definite pathologic findings present in the rectal mucosa but do not have any clinical symptoms.

The diagnosis of schistosomiasis must be considered in any person who has lived in a geographic area suspected of harboring *S. mansoni*. It is the responsibility of the physician to rule it out by careful repeated examinations of the stools by any and all concentration methods even though no symptoms are present. Infection with *Schistosoma mansoni* indicates schistosomiasis. There is no such condition as a healthy carrier of schistosomiasis.

William Harvey.—William Harvey (1578-1657), the greatest name in English medicine and one of the greatest names in all experimental science, was born in Folkstone. He attended Granville and Caius colleges, Cambridge, and afterward studied at Padua, where his professor was Fabricius, whose work on the valves in the veins and the development of the chick profoundly influenced Harvey's two great works. He returned to England, taught at the College of Physicians in London, saw military service in the Civil War on the Royalist side, died in London at an advanced age and was buried at Hempstead, Essex. *De motu cordis et sanguinis* (On the Motion of the Heart and Blood) was published in 1628 and went through many editions. *De generatione animalium* (on the Generation of Animals), published in 1651, gives him the right to the title of the father of embryology. It has been claimed for others that they announced the circulation of the blood. Undoubtedly this is partially true. Fabricius described the valves in the veins, but he missed their significance. Servetus (*Christianismi Restitutio*, 1553) described the pulmonary circulation. Cesalpinus and Realdus Columbus both described the circulation, but from speculation; Harvey proved it by experiment.—Clendening, Logan: Source Book of Medical History, New York, Paul B. Hoeber, Inc., 1942.

AMEBIC ABSCESS OF THE LIVER UN SUSPECTED UNTIL PERFORATION

CAPTAIN WALTMAN WALTERS, MC-V(S)
CAPTAIN CHARLES H. WATKINS, MC-V(S)
LIEUTENANT HUGH R. BUTT, MC-V(S)

AND

LIEUTENANT COMMANDER JAMES M. MARSHALL
MC-V(S)

UNITED STATES NAVAL RESERVE

The sudden perforation of unsuspected, asymptomatic amebic abscesses of the livers of 2 naval patients returning from the South Pacific combat zone has led us to speculate on the possibility that a similar type of condition may be encountered among other persons who are returning from these regions. Because of the considerable delay between the onset of symptoms and the recognition of the disease in the 1933 epidemic and the consequent loss of life, it seemed advisable to report these 2 recent cases.

The patients were enlisted personnel of the Navy who had been on duty on one of the islands in the South Pacific war zone. They were returned with diagnoses of filariasis which they had on admission to a naval hospital on the mainland.

In both cases a diagnosis of amebic abscess of the liver was made only after perforation of the abscess to the subdiaphragmatic region. In the first case, although emetine therapy was instituted and a definite specific response was obtained, surgical drainage seemed advisable because of progressive signs and symptoms of impending perforation of the abscess through the diaphragm into the right pleural cavity. In the second case, in spite of daily doses of emetine for three days, the symptoms and signs were so acute and severe that perforation of the abscess into the peritoneal cavity was feared, and immediate operative drainage seemed imperative.

Of striking significance in each case was the similarity of symptoms when the abscess perforated to the right subdiaphragmatic region. These symptoms consisted in the sudden development of aching pain in the right shoulder, in the right costovertebral region and lower portion of the right thorax associated with chills and fever. The thoracic pain extended to the abdomen, and muscle spasm was present in the right upper quadrant. Roentgenograms of the thorax revealed no evidence of pneumonia but progressive elevation of the right half of the diaphragm and a loss of the acute cardiophrenic angle in the other. The temperature varied daily in both cases over approximately 4 degrees F., and in the second case the pulse rate increased to a maximum of 140 beats per minute on the day of operation. Pronounced leukocytosis was present in both cases. Exposure of the right subdiaphragmatic space was made through right subcostal incisions. The amebic abscess in the liver was found to communicate with the subdiaphragmatic abscess. Drainage of both was followed by progressive and complete recovery.

Captain Walters, Captain Watkins and Lieutenant Butt are on leave of absence from the Mayo Clinic, Rochester, Minn.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

REPORT OF CASES

CASE 1.—On Jan. 16, 1943 a man aged 23 was admitted to the hospital from the South Pacific zone with a diagnosis of lymphangitis of the right spermatic cord. The right epididymis and right spermatic cord had been swollen for four and a half months. He was studied thoroughly by the Filial Commis-

Fig. 1 (case 1).—Temperature chart showing intermittent fever following perforation of amebic abscess of the liver to right subdiaphragmatic region. The response to full course of emetine therapy may be noted.

sion. It was possible to place him on outside duty on March 9, and later he was placed on an outside work detail. Roentgen therapy was given over both inguinal and femoral regions, left axilla and left epitrochlear region from April 7 to 14 inclusive. On the patient's return from a therapeutic leave of thirty days he was placed on the outside detail, which involved hard work. Swelling of the spermatic cord or epididymis did not recur.

Fig. 2 (case 1).—Elevation of right half of diaphragm on July 5, 1943.

Considerable tenderness and muscle spasm were present in the upper part of the abdomen on the right side. The liver was enlarged and tender. The leukocyte count was 28,000 per cubic millimeter of blood. Roentgenographic examination of the thorax was negative. Administration of sulfadiazine was started on June 16. A chill occurred on June 17, but the blood smear made at that time was reported negative for malaria. On June 20 the patient still complained of severe pain in the lower

part of the thorax. Repeated roentgenologic examinations of the thorax after June 16 showed a progressive elevation of the right half of the diaphragm with an irregular dome-shaped bulge (figs. 2 and 3).

The patient gave a history of having had amebiasis in 1941 with positive findings on examinations of the stools. After a course of emetine therapy stool examinations had given negative results and at the time of the admission to the hospital in June 1943 gave negative results for ameba. There had been no diarrhea.

On June 23 a diagnosis of subdiaphragmatic abscess on the right side was made. Treatment with emetine hydrochloride and carbarsone was started; 3 grains (0.2 Gm.) of emetine hydrochloride was given on the first day, 2 grains (0.13 Gm.) on the second day and then 1 grain (0.065 Gm.) the following four days; a total of 9 grains (0.6 Gm.) was administered. Two days following the institution of emetine therapy the patient's temperature returned to normal and varied from 97.5 to 99 F. for twelve days. During this time the right half of the diaphragm continued to elevate progressively.

Drainage of the subdiaphragmatic abscess was decided on, and accordingly this was done on September 7. An abscess cavity 10 cm. in diameter was found in the right lobe of the liver, with an opening 5 cm. in diameter into the subdiaphragmatic abscess cavity. Both cavities contained approximately

Fig. 3 (case 1).—Increase in elevation of diaphragm on July 23, 1943.

1,000 cc. of yellowish white, thick, purulent debris with clots of fibrin. Smear and culture revealed gram-positive cocci. A strip of iodoform gauze impregnated with sulfanilamide powder was placed in the cavity of the liver and Penrose drains in the subdiaphragmatic abscess cavity.

The temperature rose to 101.5 F. for two days after operation and then returned to normal. Roentgenologic examination of the cavity, after injection

of radiopaque oil (lipiodol) revealed that the cavity was decreasing progressively. A catheter, which was inserted into the abscess cavity in the liver for drainage at the time of operation, was removed completely on October 12. Healing of the sinus occurred in a few days. Since that time the patient has been well and afebrile.

CASE 2.—A man aged 23 was admitted to the hospital on Aug. 6, 1943 with diagnosis of lymphadenitis. He had served in Samoa from March 19, 1942 to Jan. 17, 1943 and in New Caledonia, New Hebrides and Russell islands until July 13, 1943.

On September 3 the patient was examined by the Filial Commission, which found a little residual evidence of adenitis. He was placed on outside detail, which involved hard work. On September 30 he complained of sore throat; on examination his temperature was 99.8 F. and his throat was red and infected. Culture of material from the throat revealed hemolytic streptococci. Accordingly on October 1 the diagnosis was changed to acute pharyngitis. On October 4 the patient complained of severe spasmodic pain in the right upper quadrant of the abdomen with tenderness and muscle spasm particularly in the region of the upper right rectus muscle. The condition was thought to be diaphragmatic pleurisy or beginning amebic abscess of the liver. The patient had pain and tenderness over the right lower portion of the thorax and abdomen, intermittent fever to 103 F. and an occasional chill (fig. 4). Progressive downward enlargement of the liver occurred. The leukocyte count was 19,500 per cubic millimeter of blood. Roentgenologic examination of the lungs showed no evidence of pneumonia but a widening of the cardiophrenic angle (fig. 5).

Blood culture was negative, as was examination of the stool for amebas. The patient was given 1 grain (0.065 Gm.) of emetine on October 7, 8 and 9 without apparent benefit. Roentgenograms of the thorax on October 9 revealed an increase in the elevation of the right side of the diaphragm and no evidence of pneumonia.

Fig. 4 (case 2).—Temperature chart showing septic type fever with proportionate increase in pulse rate. Temperature and pulse failed to respond to administration of emetine and were increased at time of emergency surgical drainage.

A diagnosis of hepatic abscess of unknown origin was made and, in view of the extremely serious condition of the patient, the progressive increase in the pulse rate to 140 beats per minute and the temperature to 103.5 F., operation seemed advisable. This operation was undertaken in spite of the possibility that an amebic abscess of the liver with perforation might be encountered and that an inadequate amount of emetine had been given. On October 9 a subdiaphragmatic abscess containing about 8 ounces (240 cc) of typical amebic material was drained through a right subcostal incision. An abscess cavity approximately 12.5 cm. in diameter was found in the

Fig. 5 (case 2).—Elevation of right half of the diaphragm with a change in the right cardiophrenic angle to a right angle.

right lobe of the liver by needle aspiration. This cavity was opened and about 500 to 700 cc. of creamy white pus with fibrin and cellular debris was drained out. Smear and culture revealed *Endamoeba histolytica*. A strip of iodoform gauze, impregnated with 5 Gm. of sulfanilamide, was inserted into the abscess cavity within the liver. This was removed on the twelfth postoperative day after repeated daily soakings with 1:5,000 solution of potassium permanganate. Penrose drains were used to drain the subdiaphragmatic abscess.

On the evening of the day of operation the patient gave evidence of shock, with rapid pulse rate and blood pressure of 76 mm. of mercury systolic and 54 mm. diastolic. Five hundred cc. of blood plasma was administered. Two grains (0.13 Gm.) of emetine was injected subcutaneously on the day of operation and 1 grain (0.065 Gm.) each day thereafter for

seven days. After removal of the gauze pack from the abscess cavity in the liver, a catheter was inserted into it for irrigation and drainage in order to allow complete closure of the cavity. The fever decreased by lysis and became normal on October 17. The cavity obliterated itself and the sinus healed after removal of the catheter.

COMMENT

Amebiasis is a much more frequent disease than has been commonly supposed. It is certainly endemic in many portions of the United States and present in all sections. With the present worldwide dispersal of our armed forces and their subsequent return home, this disease will be encountered with increasing frequency. The percentage of cases of amebiasis in which amebic hepatitis or abscess develops is unknown and depends on several factors, chief of which are promptness of recognition and thoroughness of treatment. It seems reasonable to suppose that under utopian conditions, if all patients with fresh infections of *Endamoeba histolytica* were promptly and thoroughly treated amebic disease of the liver would not occur, as hepatic involvement is always a secondary complication to the disease in the colon. This statement does not mean that every patient who has amebic disease of the liver has a diarrhea or even that he has had diarrhea. It is apparent that many amebic infections of the colon are largely asymptomatic. Of Ochsner and DeBakey's¹ 741 collected cases a history of diarrhea was found in 58 per cent and diarrhea at the time of the patient's admission to the hospital because of the amebic disease of the liver was found in only 21 per cent. Seventeen and four tenths per cent of the number of patients admitted because of amebic dysentery to the Charity Hospital in New Orleans had amebic abscess of the liver.

Our first patient gave a history of amebic dysentery in 1941. After emetine therapy stool examinations did not reveal any amebas and since that time noticeable or remarkable episodes of diarrhea had not occurred. He did not have diarrhea while in this hospital. In case 2 diarrhea had not occurred at any time.

Although the symptoms of amebic abscess of the liver are chills and fever, lower thoracic and upper abdominal pain accompanied by nausea and vomiting, loss of weight and weakness, these symptoms were entirely lacking in our 2 cases until the amebic abscess of the liver perforated to the subdiaphragmatic region. Enlargement of the liver and abdominal tenderness also were absent until perforation occurred. The finding of *Endamoeba histolytica* in the stools would clinch the diagnosis in cases in which the usual symptoms and physical findings are encountered. *Endamoeba histolytica*, however, was absent from the stools of both our patients.

Ever since Rogers² in 1922 clarified the etiology, pathology and treatment of amebiasis of the liver, the problem has been one of increasing medical and decreasing surgical significance. Nevertheless, the surgeon plays an important, and frequently dramatic, role in the successful treatment in these cases.

As a result of Rogers' many years of study of amebiasis in India, he was able, for the first time, to establish three fundamental facts which completely revolutionized the therapeutic concept of this disease. First, he

2. Rogers, Leonard: Amebic Liver Abscess: Its Pathology, Prevention and Cure. Lecture I. Etiology and Pathology of Amebic Liver Abscess, *Lancet*, 1: 463-469 (March 11), Lecture II. The Varieties and Treatment of Amebic Liver Abscess, *ibid.*, March 25, pp. 569-575; Lecture III. The Prevention of Amebic Liver Abscess and the Recent Reduction in Its Prevalence and Mortality, April 8, pp. 677-684, 1922.

conclusively demonstrated that amebic abscess of the liver is caused by *Endamoeba histolytica* specifically and is therefore differentiated from pyogenic abscess of the liver. Second, he proved beyond question that emetine is a specific and highly effective drug in the treatment of amebic disease of the liver. Third, he reduced the mortality rate in his cases from 57 per cent to 14 per cent by substituting emetine therapy combined with closed aspiration of the abscess for the previously used open operation. Berne³ reported the results of treatment in 63 cases at the Los Angeles General Hospital. Nineteen patients, including 3 who had hepaticobronchial fistula, were treated with emetine alone and all recovered. Eighteen patients were treated with emetine first and subsequently aspiration was performed; all recovered. Twenty-six patients were treated by open surgical drainage, some with and some without emetine; 14 (54 per cent) died.

Ochsner and DeBakey⁴ reported a series of 80 cases in which open drainage was performed with a mortality rate of 22.1 per cent, whereas by means of conservative treatment (administration of emetine hydrochloride with or without drainage by aspiration) in 83 cases they reduced the mortality rate to 3.6 per cent. Following this statement, however, they said "Of interest also is the fact that aspiration was performed without preliminary emetine in 2 of the 3 fatal cases. . . . The other patient was treated with emetine and anayodin on the medical service for almost three weeks and no attempt made to drain the hepatic abscess. At autopsy a huge hepatic abscess measuring approximately 20 cm. in diameter was found in addition to several smaller abscesses. We are firmly convinced that these three tragedies could have been averted, the first two by the preliminary administration of emetine and the third by aspiration of the abscess in addition to the use of emetine."

We believe that, whenever amebic abscess of the liver is suspected, treatment with adequate amounts of emetine should be tried first. If the patient does not recover completely or if persistent enlargement or deformity of the liver is demonstrated clinically or roentgenologically, aspiration is indicated, but it is preferable not to perform it through an uninvolved serous cavity. Open surgical drainage should be used only when acute perforation into the peritoneum or pleura is actual or impending or when there is proved pyogenic contamination.

SUMMARY

In the 2 cases of unsuspected amebic abscess of the liver reported, symptoms occurred only on perforation of the abscess to the right subdiaphragmatic region. Both patients had had naval duty at one or more of the South Pacific islands and had been returned to the mainland because of a diagnosis of lymphadenitis. In neither case was diarrhea present nor were amebas found in the stools. In case 1 the general condition improved after the administration of emetine but the subdiaphragmatic abscess increased in size and open operation was performed. In case 2 there was no apparent response to emetine. Because of the patient's critical condition, surgical drainage was performed as an emergency procedure. Both patients made excellent recoveries.

Clinical Notes, Suggestions and New Instruments

A PNEUMATIC LEG SPLINT

A PRELIMINARY REPORT

G. J. CURRY, M.D., FLINT, MICH.

Chief of Division for Surgery of Trauma, Hurley Hospital

This piece of fracture equipment is designed to employ the use of air properly encased between two layers of supporting material. It is an inflation unit for emergency care of fractured lower extremities. The two layers are cut to selected measure-

Fig. 1.—The pneumatic leg splint open. Note valve at upper thigh part, side cuffs with snaps, and hooks for lacing.

ments and sealed at the edges. The air intake is through a valve located at either the upper or the lower portion (figs 1 and 2). The latter location is preferable. Hooks are attached to the anterior coaptation edges and evenly spaced. The unit is folded around the affected part and laced with leather lacing material in the same fashion as a boot. Inflation follows, either by mouth blowing or by the use of a pump. The fractured extremity is held in manual traction by an assistant during application and inflation, being released when the desired amount of air has been introduced. This is minimal and is approximately 8 to 10 mm. of mercury, or a quantity sufficient to produce splinting comfort as evidenced by the patient's reaction.

Fig. 2.—The pneumatic leg splint closed. Lateral view. Note position of valve and the hooks for lacing arrangement. Also cuffs and snaps for Thomas splint attachment or application of additional support from poles, sticks, broom handles, mop handles and the like.

Investigation of this problem has been carried on in the Department for Surgery of Trauma, Hurley Hospital, Flint, Mich. So far only fractures of the lower extremity have

been managed, for which the splint seems more appropriate. They were simple, compound, single and multiple in type, involving the femur, knee and leg. The unit remained in place from a few hours to six days and was considered only on an emergency basis, filling the gap between the occurrence of the fracture and the beginning of some definitive type of treatment. This obviously means the phase which includes first aid and associated transportation requirements.

Fig. 3.—The pneumatic leg splint in place, inflated, for fractured tibia and fibula, lower third. Supplementary splint aids are unnecessary.

Fig. 4.—Same as figure 3, side view.

The first material used was synthetic rubberized fabric. For the past few months a more durable, pliable and specially prepared material has been obtainable in small amounts. Construction changes took place. Cuffs with snaps or buckles were added to the sides so that the splint could be attached to a Thomas splint (figs. 5 and 6). Several splints were made with a canvas covering, thus giving added protection against punctures, wear and tear. This acted as an envelop for the inner lighter compartment, the inflatable portion, making the unit quite snag proof. Reinforcements were added to areas subjected to extra stress and strain. Two sizes were made, large and medium, the difference being in length and circumference by a few inches. The use of broom and mop handles or any stick of proper size has been suggested for additional

Fig. 5.—Combination of Thomas splint and pneumatic leg splint for fractured femur—mid third. The Thomas splint is applied first and held upward. The pneumatic leg splint is folded around the extremity, deflated. The Thomas splint is then lowered, attached to the pneumatic leg splint, and the latter is inflated. Fixation and auto traction are thus produced.

support or facilitation of handling or transportation. These are attached to the splint by means of the cuffs.

For fractures involving the knee, lower end of the femur, leg and ankle the Thomas splint is not used (figs. 3 and 4). The latter is added as a supplemental aid in femoral fractures—middle and upper thirds. Application of the Thomas splint is done first, attached to the sides of the pneumatic leg splint by cuffs with snaps or buckles (fig. 5). The Thomas splint is held upward; the pneumatic leg splint is applied and inflated after attachment to the Thomas splint (figs. 6 and 8). Application with or without the Thomas splint is simple and rapid. The unit can be stored in a small space.

COMMENT

The principle of the pneumatic leg splint is similar to that of the pillow splint, except that air pressure is constant and evenly distributed. The amount of air used, as stated, is a quantity sufficient to produce splinting comfort. In all cases comfort was obtained. Transportation of the patient was accomplished with a minimum of discomfort. All movements of the lower extremity were practically painless. Frequent check-up x-ray examinations showed little or no change in the position of bone fragments. There was minimal edema at the fracture site. There was an intimate hugging of the surface contour of the extremity by the inner layer with the space for air between the layers remaining constant (figs. 7 and 9).

Fig. 6.—The pneumatic leg splint, inflated, with Thomas splint attached, for mid femoral fractures. Note pressure against the longitudinal Thomas splint bars. Traction may be added from lower foot portion of the pneumatic leg splint to end of Thomas splint.

The contact of rubber and skin over a period of time is expected to produce irritation. This finding was present over the malleoli in cases in which the splint remained in place for

Fig. 7.—Fracture of tibia and fibula at junction of middle and lower thirds. Anteroposterior view. Note inner layer of the splint hugging the surface contour of the leg. Note outer splint layer with air spaces between.

five or six days. It was negligible and quickly disappeared following removal. The application of stockinet eliminated this possible hazard. There are a great many fractures of the lower extremities that need only coaptation for emergency

splinting. The constant air pressure, however, produces in itself a certain amount (or degree) of traction by reason of a downward push against the prominences of the extremity. This has been called auto traction. The combination of a compound fracture and a burn indicates its use. The continuous pressure exerted would be helpful in the management of both conditions, and the lessened edema at the fracture and burn sites aids in

Fig. 8.—Same as figure 6, side view.

reducing secondary shock tendency, retarding absorption of the products of tissue trauma. The buoyancy afforded suggests its use as an emergency splint for a sailor with a fractured leg who has to abandon ship (fig. 10). By holding the arms outstretched and the free extremity next to the splinted one, the wearer easily remained afloat on his back with little or no tendency to listing.

Compressed air between layers of rubber or supporting material for splinting purposes is not new. However, the literature contains no available information regarding its use for treatment of fractured extremities, emergency or otherwise.

R. C. Wingfield¹ designed a pneumatic apparatus which was made of different sizes and used as a restrictor of chest

Fig. 9.—Same as figure 8, lateral view.

movement in pulmonary tuberculosis and thus aided in promoting fibrosis and healing. This preceded artificial pneumothorax. George Robertson and Ruth Millar² made hollow pneumatic rings of 1½ inches inside diameter strengthened

with cord and covered with stockinet to be used as pressure pads inside a box splint. These were substituted for the "birds' nests" formerly used, eliminating ulceration and irritation frequently found beneath the heel. The stockinet eliminated the sweat hazard. Several were used in each case. Douglas Beverly³ in discussing the local treatment of burns, describes a compression dressing called "the transparent jacket system." This is a transparent compartment with walls made of light material, having an intake and an outlet valve. While the pressure is continuous, it may be controlled in amount. The burned surface can be seen at all times. It is also used as a pressure dressing for immobilization of skin grafts

SUMMARY

A pneumatic leg splint has been successfully used many times in lower extremity fractures.

It may be combined with a Thomas splint, especially indicated in femoral fractures.

It is consistently comfortable.

There is minimal edema at the fracture site.

Pressure is low, constant and evenly distributed.

Fig. 10.—The pneumatic leg splint in place on a right lower extremity, showing buoyancy in water. There were 20 inches of water in the Hubbard tank. By keeping the arms slightly outstretched, the patient's head and trunk remained up. There was a slight list to the unaffected side. This was controlled by changing position of the unaffected extremity. Application of a Mae West life jacket would obviously be an additional safety factor.

It is quickly and easily applied.

It is recommended only as an emergency and transportation unit.

It can be used as a pressure dressing for complicating lower extremity burns.

It floats.

It may be useful as an added piece of fracture equipment, aboard ambulances, emergency hospital services and in the surgical divisions of the armed forces.

Experimental work continues.

Arrangements are being made for the commercial supply of the unit under patent protection.

Council on Industrial Health and Council on Pharmacy and Chemistry

Many hundreds of articles have been published on the treatment of burns. Some of these have been excellent reviews, but frequently they were published in periodicals not available to the majority of the medical profession, were out of date almost as soon as prepared, or emphasized some aspect of treatment which later was disputed warmly. Other communications presented information in an orderly and concise fashion which made them almost necessary additions to every medical library. One such book that has been well received is *Burns, Shock, Wound Healing and Vascular Injuries*, prepared under the auspices of the Committee on Surgery of the Division of Medical Sciences of the National Research Council (1943).

Nevertheless, many letters arrive at the office of the Council on Industrial Health and the Council on Pharmacy and Chemistry asking for information on the treatment of burns. These letters indicate the need for a status review which will present in digest form pertinent facts relating to the various methods now commonly employed to treat burns. The following review is offered for this express purpose. It is not for the specialist but for the general practitioner and the industrial physician. It is hoped that the report will show that the ideal agent has not been developed, that highly complex mixtures are as irrational for this form of treatment as for others, that each new highly publicized treatment or drug should be studied with a critical eye before accepting the accompanying claims, that the best treatment on the whole is the simplest and that any treatment is a tedious and painstaking undertaking. On many occasions the Council on Pharmacy and Chemistry has been asked to consider some proprietary drug or mixture proposed for the treatment of burns with an astounding array of claims. With few exceptions the claims have far exceeded the therapeutic value, and not infrequently the agent sooner or later has sunk into obscurity. A complete bibliography for this report will be included in the reprints.

LOCAL TREATMENT OF THERMAL CUTANEOUS BURNS

Over one thousand papers dealing with burns have been listed in the *Quarterly Cumulative Index Medicus* during the past decade, and the number is increasing rapidly under the stimulus of the high incidence of thermal burns in the present war. Some two hundred articles largely concerned with local treatment alone have appeared in the last few years (Harkins¹ listed seventy-five different preparations which have been proposed for local burn therapy). Examination of these reports supports the belief expressed by many authors that there is at present no single preparation or method of therapy which will meet the needs of every case or solve all the problems involved in the treatment of a burned area.² However, some of the more widely used local methods may give acceptable results if properly applied and if the systemic treatment of the patient is adequate.³ Bettman,⁴ Buuyan,⁵ Harkins,⁶ Laverder,⁷ Aldrich,⁸ Wakeley,⁹ Allen and Koch¹⁰ and Atkins,¹¹ to name only a few, have reported excellent results on large series of patients while employing widely varying local measures of treatment. The only factor common to the procedures used by each of these authors, other than systemic treatment, was thorough but gentle cleansing of the burned area under rigidly aseptic precautions.

Local treatment of burns is in a state of flux, which is apparent to all who are familiar with the subject. The unsatisfactory results obtained with some of the older methods of treatment have led to considerable experimentation. In spite of the voluminous literature and the many reviews of the local methods of burn treatment,¹² the lack of careful comparative study of these measures leaves a place for a definitive statement of the effects which local treatment seeks to produce and the results which may be expected from the application of the more widely used methods.

It is not the function of this report to discuss the systemic treatment of burns, the aim of which it is agreed is the return to a normal physiologic state. The direction and degree of such alterations can now be determined and the means for producing the necessary corrections are generally known.¹³ The office of the Surgeon General¹⁴ issued a circular letter for the treatment of burns in the Army. It outlined the prevention and the treatment of shock, the administration of adequate amounts of morphine and the intravenous infusion of plasma, prophylactic chemotherapy, prophylaxis against tetanus and possibly gas bacillus infection and local treatment.

Later the Medical Division of the Office of Civilian Defense¹⁵ announced a revision of the pamphlet "Treatment of Burns and Prevention of Wound Infections" to incorporate new techniques and to recognize directions of the Committee on Chemotherapeutic and Other Agents and the Subcommittee on Burns of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. The most notable change in the pamphlet is the withdrawal of the recommendation of the use of ointments or jellies containing tannic acid in the first aid treatment of burns. The pamphlet describes "open"

and "closed" treatment for burns. The "open" treatment, apparently the treatment of choice, consists essentially of the application of boric acid ointment or petrolatum, with pressure dressings. (More recently, boric acid has been criticized because of its toxic properties.) The "closed" treatment (tanning or eschar method) is recommended only if not more than twenty-four hours has elapsed, if the burned area has not been grossly contaminated, if strict surgical asepsis is employed and if coagulation is readily accomplished.

The liberal administration of oxygen also has been advocated.¹⁶ Few surgeons will proceed with more than preliminary care of the burned area before shock is controlled. The following discussion of local treatment is made with the assumption that the probably greater importance of proper systemic treatment is recognized and that such treatment will be carried out.

The usual classification of burns as to depth has been heeded in this report. First degree burns include only those which involve the most superficial layers of the skin and produce simple erythema. Second degree burns produce blistering and may be of varying depth but always leave intact some elements of the skin, providing islands of epithelium from which regeneration can occur. In third degree burns the full thickness of the skin is lost, and these always require skin grafting for rapid healing of even moderately sized areas. The latter group includes the deeper burns (grades 4, 5 and 6, Dupuytren).

Obviously a discussion of the proper time and methods to be used for grafting deep burns has no place in a review such as this and is omitted. Subsequent discussion on treatment is limited to the medicinal preparations more commonly employed at this time.

TANNIC ACID

Tannic acid was introduced by Davidson¹⁷ primarily to fix and prevent the absorption of toxic substances from the burned area. Many authorities today are not willing to admit that this fixing action of tannic acid is responsible for any effectiveness in reducing the mortality rate of severe burns, and a wave of disapprobation has followed the use of this substance in the present war.¹⁸ Probably the first denial that tannic acid has reduced the mortality rate in burns came from Stanley J. Seeger, based on statistical material from Milwaukee Children's Hospital. However, the benefits which may have followed its use and the reasons for its failures should be examined critically in view of its past popularity. It has been stated frequently that an escharotic produces the following effects by sealing over a properly prepared burned surface:

1. Lightens shock by lessening or abolishing pain and the external loss of plasma.
2. By forming an impervious covering, prevents the invasion of bacteria and thereby secondary infection.
3. By forming a painless, tough dressing which does not require frequent changing, makes the patient comfortable, decreases nursing care and allows for ready transportation.
4. By fixing "burn toxins," if any, prevents their absorption and consequent systemic effects.
5. Lends itself to the adequate handling of large numbers of casualties.

Despite the beneficial effects, it must be admitted that tannic acid has its disadvantages, and some unfortunate experiences have followed its use. Those most commonly reported in the literature are the following:

1. The eschar develops slowly and requires frequent applications, thus allowing considerable pain and external plasma loss and requiring the time of a comparatively large nursing staff during the first twenty-four hours.

2. The eschar formed is thick, inflexible and unyielding. On circumferential burns and over the pulps of the fingers it tends to produce ischemic and pressure necrosis. Over joints it tends to crack or, by prolonged immobilization (especially of the fingers) to produce fixation. It tends to curl at the edges; this curling and the formation of multiple cracks allows openings for secondary invaders. On the face it produces unpleasant immobility and by contracting tends to distort yielding structures. Ectropion often follows the use of tannic acid on burns of the eyelids.

3. Near body orifices, especially on the perineum, its integrity cannot be maintained and infection supervenes.

4. Infection once started spreads rapidly and the focus of infection is not readily found under the thick, rigid eschar. Many workers feel that it is impossible to prevent infection from developing beneath the eschar, especially in third degree burns. If infection develops, most surgeons agree that the eschar should be removed, a painful procedure.

5. Remaining islets of epithelium may be destroyed by the fixing action of tannic acid or the surgery which may be required to remove the eschar. Tannic acid has been reported to cause liver cell necrosis.

6. If third degree burns are treated with tannic acid a proper eschar is difficult to produce. Once formed, the eschar delays sloughing of devitalized tissue, the formation of healthy granulation tissue and the preparation of the wound for grafting. Further, the formation of an eschar over deep burns provides an ideal environment for the development of infection in areas where antiseptics and the escharotic cannot reach.

7. Tannic acid is said to be capable of causing liver damage.

In reviewing the literature with the aforementioned factors in mind there is almost complete unanimity on certain points. Thus, while Atkins¹¹ and Ogilvie¹⁹ report that if done properly tanning of the hands produces no further damage, it is generally agreed that tannic acid should not be used on the face, hands, feet or surfaces near body orifices where contamination is probable (perineum, genitalia²⁰). If circumferential burns of the extremities are tanned, the limb must be constantly watched for interference with the distal circulation,²¹ and preferably the tan should be split lengthwise to allow for the development of edema.²² Great care must be used to prevent permanent fixation of joints involved in the eschar.²³ Although immobilization to insure rest of a limb is widely recommended,²⁴ it may be considered safest not to use tannic acid on areas which will be immobilized in a constricting shell if an escharotic is used.

Other than shock, the most common complication of a burn is secondary infection.²⁵ Although a fresh burn has been said by some to be made sterile by the action of the causative agent, in practice all burns may be regarded as contaminated.²⁶ Moorhead's dictum "A burn is an infected wound due to heat"²⁷ warrants consideration. It is a common saying that tanning a burn without proper cleansing and débridement is akin to primary closure of an infected wound.²³ It follows that an essential preliminary to the application of tannic acid or any other escharotic is the careful cleansing of the burned area and the most thorough débridement practical under the most rigidly aseptic conditions.²⁸ The necessity for careful masking of the surgical team has been emphasized again and again.²⁹ There should be no compromise in this regard. The surgeon who has charge of a burned patient has a responsibility which can be fulfilled only by the application of much care and a great deal of hard work. There are two exceptions to the rule of the earliest possible (after control of shock) complete aseptic preparation of the burned area: in extensive burns when the immediate danger to life is great a local application may be life saving,⁹ and when there are a large number of victims thorough preparation may be impossible.³⁰

In each of these conditions the surgeon's responsibility has not ended with the local application. A complete preparation should be done as soon as possible. Many of the infections occurring under a tannic acid eschar may be due to lack of attention to the proved surgical principle: adequate preparation of a contaminated wound before primary closure.³¹ Harkins's⁶ "principle of time" is important. Harkins has stated that tannic acid should never be applied after twenty-four hours without due reason. Todd³² considers any burn older than twelve hours to be infected and treats it as such.

Most investigators of burn therapy prefer to clean and debride the affected area under an anesthetic.³³ Because of its convenience, intravenous anesthesia was hopefully tried,³⁴ but the results were not promising.³⁵ Gas and ether are preferred.³⁶ If suitable apparatus and a skilled anesthetist are not available, open drop ether is recommended.³⁷ Some assert that no anesthetic should be used if possible.³⁸ Koch states that morphine analgesia is sufficient if the preparation is gently done.¹⁰ Vigorous scrubbing and harsh cleansing agents are generally frowned on.³⁹

The after-care of the tan is vitally important in guarding against infection.⁴⁰ Bacteria find entrance from the edges and through cracks in the eschar.⁴¹ The daily painting of these ports of entry with 1 per cent gentian violet⁴² or Aldrich's⁴³ triple dye mixture, or dusting with sulfanilamide powder¹⁹ has met with some approval. Daily rigorous inspection of the tan is essential.⁴⁴ If infection occurs the tan over the area may be removed⁴⁵ by moist saline packs or baths or by surgery, the infected area cleaned with warm saline solution, sodium hypochlorite or Dakin's solution,⁴⁶ and treated with sulfanilamide powder and warm saline soaks⁴⁷ or with the aniline dyes.⁴⁸ In this and all subsequent discussion "saline solution" will be taken to mean "isotonic solution of sodium chloride."

Third degree burns heal naturally by the sloughing of devitalized tissue, the formation of granulation tissue and the growth of epithelium from the edges, a long, inefficient process. Such healing is said to be greatly hastened by surgical care which involves the judicious removal of dead tissue,⁴⁹ prevention of infection and the earliest possible skin grafting of all third degree burns. Covering such wounds with an eschar hinders this program, and many authorities are of the opinion that an escharotic should never be used on third degree burns.⁵⁰ Immediate excision and grafting of localized deep burns has been advocated,⁵² and there appears to be evidence to recommend this action. It is, however, often difficult to distinguish with certainty the depth of a burn before several days have passed.⁵² At present, if an escharotic is to be used no distinction should be made as to the depth of the burn unless full destruction of the skin can be definitely ascertained.⁵³ Even then, in certain cases the application of an escharotic over deep burns of broad surfaces may be justified as a life saving measure.⁵⁴

That the production of the eschar with tannic acid is a slow process and that the eschar formed is thick, constricting and inflexible cannot be denied.⁵⁵ Several modifications have been prepared to overcome this difficulty. A stronger (20 per cent) solution of tannic acid has been claimed to produce a satisfactory eschar much more rapidly than the usual (5 to 10 per cent) concentration.⁵⁶ Bettman⁴ proposed that following the initial application of 5 per cent tannic acid the area be painted with a 10 per cent silver nitrate solution. This procedure is said to produce quickly a thin, pliable, tough eschar and it has been widely used.⁵⁷ A further modification in which the first application was a 1 per cent gentian violet solution followed by tannic acid (9 per cent) and silver nitrate (10 per cent) has been advocated.⁵⁸ The eschar formed was similar to that produced by Bettman's procedure. The gentian violet apparently served entirely as a preliminary antiseptic treatment of the burned area. Because of the rapidity with which the eschars are formed and their thinner, more flexible, nature these last two methods seem to offer advantages over 5 per cent tannic acid. Still another modification was reported by Richards.⁵⁹ He advocated an alcoholic solution of tannic acid which was said to produce a thin eschar rapidly while at the same time the alcoholic menstruum acted as an anti-

septic application. The discussion of the necessity of thorough preliminary cleansing and the principles of site and time apply⁶ for these procedures just as much as for tannic acid alone.

Tannic acid is reported to fix and destroy remaining islands of epithelium,⁶⁶ although this action has not been proved beyond dispute. It has not been demonstrated that this effect can convert a deep second degree to a third degree burn, as can infection.⁶¹

A good portion of the case built up by Wells, Humphrey and Coll⁶² for tannic acid as a liver poison when applied to burned areas rested on the observation that prior to the widespread use of this substance liver lesions had not been recognized in fatal burn cases. Boyce⁶³ contradicted this assumption; Wolff, Elkinton and Rhoads⁶⁴ and others⁶⁵ have shown that liver changes and decreased function occurred in burns per se. However, Wells and his co-workers proved by intravenous injection that tannic acid, if it reaches the liver, can produce definite destruction of liver cells. The importance of this fact merits further investigation.

ANILINE DYES

Aldrich⁶⁶ introduced the use of gentian violet and later a mixture of three dyes (gentian violet, brilliant green and acriflavine)⁸ on the theory that burn "toxemia" was due to the invasion of bacteria. Aldrich's theory of the etiology of the acute toxemia of burns has not been generally accepted, although the agents he introduced and his outline of treatment⁶⁷ retain their utility. The dyes when applied in a 1 per cent solution or as a jelly produced a tough, thin, flexible eschar which developed slowly. It was said that they did not destroy remaining islands of epithelium and that they did not cause liver damage. Since the dyes are fixative agents it is possible that they are not completely harmless to damaged epithelial cells.⁶⁸ Both preparations possess considerable bacteriostatic and bactericidal power against gram positive organisms, and the mixture of three dyes against gram negative organisms as well.⁶⁹ This property may be considered a useful adjunct in the preparation of an aseptic surface prior to the application of the escharotic, much as the gentian violet, tannic acid and silver nitrate procedure just discussed. Eschars produced by these or any other tanning agents have not been shown to have any bactericidal or bacteriostatic action. It has been often overlooked that infection can readily occur under eschars produced by these agents.⁷⁰ Thorough preliminary cleansing under rigid aseptic technic should be considered when these dyes are used, as when any of the variants of tannic acid therapy are employed.⁷¹ The advantage was claimed that local areas of infection and suppuration could be detected early under a dye eschar, since its presence was betrayed by softening.⁷² This would be helpful, but constant daily surveillance remains a necessity if the spread of infection is to be avoided.⁷³ Since the application of the dyes produces an eschar, the same limitations apply to their use as to tannic acid; this applies to the face, hands, feet and on surfaces near body orifices. Extreme care should be employed when they are used on circumferential burns of the extremities or over joints. While some workers accept their use on the hands and face,⁷³ others do not. Most tanning agents can be used to build up an eschar of any desired thickness, depending on the concentration of the solution and the number of applications; the aniline dyes are no exception.⁷⁴ Disadvantages lie in the slowness with which the eschar develops and in the messiness of the treatment. Branch,⁷⁵ combining the use of gentian violet with silver nitrate, reduced the time required for eschar formation. This method would seem to compare with the tannic acid-silver nitrate technic of Bettman.

Brilliant green has been used alone in the same manner as gentian violet. The results were said to be promising, although no data were given.⁷⁶

SULFADIAZINE SPRAY

Pickrell⁷⁷ reported that a solution of sulfadiazine in 8 per cent ethanolamine when sprayed over a burned surface produced a thin, transparent, flexible eschar. The entire application required four days, and it has been stated⁷⁸ that the tan produced was so thin that second degree burns were painful and the transportation of all types of burns difficult. Never-

theless, several authors appear enthusiastic over this treatment.⁷⁹ Comments have been made on the procedure advocated by Pickrell of spraying the solution over the burned area with no preliminary cleansing.⁸⁰ The absorption of sulfadiazine has been reported to cease after the eschar is formed;⁸¹ extensive use of sulfadiazine, however, should be accompanied by the same precautionary observations as when sulfadiazine is administered orally. The method has not been reported on sufficiently for final judgment to be made. It shows promise and seems worthy of trial, although the slowness with which the eschar develops is a serious disadvantage. Preliminary cleansing should not be omitted if at all practical.⁸²

SALINE BATHS

The unpleasant results following the use of tannic acid on extensive third degree burns and on burns of the hands led to a trial of warm saline baths as a method for the treatment of burns.⁸³ Good results were reported. Sloughing of devitalized tissue and the control of infection were promoted, while the rapid preparation of granulating surfaces for grafting and the ability to maintain active movements were noted. External loss of plasma was not decreased, and the frequent changes of dressings were apt to be painful. A considerable amount of apparatus and much nursing care were required. The method will not adapt itself to many hospitals or to the handling of large numbers of patients. Transportation of such patients is not practical. Notwithstanding these difficulties, the method may have an application in selected cases, as in infected burns. Between baths the area may be sprinkled with sulfanilamide and kept moist with warm saline packs. The application of this procedure to infected and special areas such as the hands has proved valuable.⁸⁴

An alternative and similar method utilized the application of tulle gras or similar dressing and moist saline dressings after first cleansing the area and sprinkling with sulfanilamide.⁸⁵

The outer dressings were changed frequently but the tulle gras was left in place, obviating the pain attendant on a complete change of dressings. These methods were especially useful for infected or grossly contaminated burns or burns of the hands, feet, face and perineum.

OILED SILK (BUNYAN) ENVELOP

Bunyan⁵ sought a method which would aid the healing of burns by gentle but thorough cleansing and by the removal of dead tissue while avoiding irritant applications. The dressing desired should be painless and allow active and passive movements. The treatment should not aggravate burn shock but diminish or inhibit loss of body fluid, reduce absorption of toxins and disinfect without further damaging tissues.

He believed that the closest approach to this ideal involved the use of electrolytic sodium hypochlorite (in the form of "milton," a 1 per cent solution), which was said to be nontoxic, antiseptic and stimulating to growth but destructive to dead tissue. The preliminary cleansing was done with a 10 to 20 per cent solution of the original preparation. The wound was irrigated three times daily with a 5 per cent (or less) concentration. To form a painless, airtight dressing within which the frequent washings could be carried out, oiled silk envelopes were devised and fitted with inlet and outlet tubes through which the solution could be passed. It is not generally recognized that the oiled silk envelop formed a dressing analogous to an eschar, with the same effect of relieving pain, avoiding frequent changes of dressing and allowing ready transportation. The oiled silk was said not to stick to the burned area, was easy to apply and, being transparent, allowed inspection of the wound at all times. The method aided sloughing of devitalized tissue, exerted a continued cleansing action and minimized or prevented infection in every way analogous to a continuous bath with the added advantage of a sealing, sterile, painless dressing. The envelopes in reality formed a local bath. The irrigating solution employed may be isotonic solution of sodium chloride, a solution of one of the sulfonamides, or Dakin's solution instead of the solution of electrolytic sodium hypochlorite.⁸⁶ Bunyan⁵ reported that saline solution caused maceration of the tissues, which the sodium hypochlorite solution did not. Some pain may be experienced if the irrigating solution is too strong, and the tight seal may increase the

edema of the enclosed portion.⁸⁶ The method has proved useful for isolated areas such as the hands, feet and limbs and requires simple yet specialized apparatus. It is not labor saving when only 1 or 2 patients are treated but is said to reduce considerably the nursing care of a full ward. The method remains to be more adequately tested, especially for extensive burns. If the equipment is available it would seem to be a valuable means of treating deep, grossly contaminated or infected burns, especially of the hands, feet and limbs.⁸⁷ The irrigating solution may be changed at any time to meet the demands of the wound or the wishes of the surgeon.

PRESSURE DRESSINGS

The method of pressure dressings, so ably presented by Allen and Koch,¹⁰ has been termed the "physiological"⁸⁸ and "surgical"⁸⁹ method by other writers. It was devised in an effort to follow well founded surgical principles and to violate none of the physiologic factors which govern the healing of any wound. Essentially it consisted of thorough cleansing and débridement, preferably without an anesthetic, after which the wound was covered with petrolatum gauze and a pressure dressing applied to inhibit both internal and external plasma loss. Immobilization of the affected part for twelve to fourteen days was enforced. During this period the dressings were not changed without due cause. Good results have been recorded.⁹⁰ It is imperative that all who follow Koch's regimen should follow it in detail. Thorough study of the writings of Allen and Koch¹⁰ and of Siler⁹¹ is a necessity. Although the method has been criticized as impractical for handling large numbers of casualties,⁹² this point apparently remains to be settled.

Variants of the method have been used. Zciss⁹³ reported on a revival of the paraffin dressing used widely prior to the introduction of tannic acid. His method is similar to that of Koch except that the dressing, built up with paraffin and constituting a pressure bandage,⁹¹ is changed daily. While this frequent dressing was criticized,⁹⁵ it was pointed out that the burns on which the method was used were deep, the daily dressing was not painful, it allowed constant inspection and sloughing tissue could be trimmed away.

There has recently been advocated in England an adaptation of the Trueta and Orr closed plaster technics to burns.⁹⁰ Such immobilization was earlier used by Lohr.⁹⁷ It does not constitute a pressure bandage and, while it may be of some advantage in the late treatment of debilitated patients with burns of the extremities,⁹⁸ it has not yet proved its worth as a routine measure.

GROWTH STIMULATING PREPARATIONS

Innumerable preparations have been developed and proposed for the treatment of burns because of their claimed "growth stimulating" properties. The active ingredients comprise a large and expanding group, including such substances as cod liver oil, various vitamins and hormones, allantoin, urea, sulfhydryl bearing compounds, cell extracts and the as yet undefined "wound hormones." It is not the function of this article to discuss the extremely complex factors which govern the healing of wounds or the alleged growth stimulating properties of various agents. It should suffice to point out that wound repair is an intricate subject depending on many factors. Observations on the time of healing of wounds with any such factors uncontrolled are not conclusive. Not one of the proposed preparations has been generally accepted by those who are authorities in this field. Those interested in the subject or who desire to make growth stimulating claims for any substance should read carefully such articles as that of Young, Fisher and Young.⁹⁹ These authors point out the common error of basing claims on insignificant data without respect to the biologic variations which count so much in the healing of a wound. In certain cases, as in burns in the "indolent stage," stimulating dressings could be of value but, when healing is proceeding at the usual rate, it is questionable whether the use of such preparations is rational. The situation would seem to be analogous to the administration of vitamin C to a person already adequately supplied. Finally, no preparation, no matter how potent in growth stimulating properties, can stimulate epithelial regeneration when the full

thickness of the skin is destroyed. Such growth must occur from the edges of the wound. No dressing can substitute for early and adequate skin grafting in third degree burns.

MISCELLANEOUS

Certain highly complex preparations have been formulated for use on burns. Several writers have reported excellent results following their use when the systemic needs of the patient were met.¹⁰⁰ It is doubtful if better results were obtained in these cases than if simpler preparations had been used. The employment of irrational mixtures is at variance with the modern concept of any form of therapy and the Council on Pharmacy and Chemistry has issued many reports on the use of such mixtures.

Mercurochrome has been proposed as an antiseptic escharotic.¹⁰¹ It was said to produce quickly a thin, tough eschar and at the same time aid in the preparation of the burned area. It has one insurmountable objection: absorption from the burned area may be great. Several instances of mercury poisoning have followed its use in this manner,¹⁰² and it probably should never be employed on burns.¹⁰³

Various substances dissolved or suspended in an alcoholic menstruum have been suggested.¹⁰⁴ Whatever the character or advantages of the use of the active principle, the application of strongly alcoholic solutions to raw areas is to be condemned. The pain attendant on such use could be of a shocking nature.

A variety of ointments and oily dressings, usually containing a bacteriostatic agent, also have been proposed for use in deep burns and burns of the hands and face, always under a sterile dressing.¹⁰⁵

THE USE OF SULFONAMIDES IN BURN THERAPY

That the sulfonamides should be used in the treatment of burns was inevitable, for the ever present danger of infection made their trial necessary. Their value seems assured,¹⁰⁶ but the procedure by which they are best used has not been established. Sulfadiazine spray has already been discussed. Powders have caused mechanical difficulties (caking) and have not been ideal for sprinkling over extensive weeping wounds.¹⁰⁷ Further, the size of the raw area could in certain instances allow massive absorption.¹⁰⁸ More recently, however, there have been attempts to vary the size of the sulfonamide particles and more success in this technic may result.

Various dosage forms have been advocated. A dispersion in a water soluble jelly was proposed for use on the hands, face and genitalia and as a first aid application.¹⁴ Robson and Wallace¹⁰⁹ recommended a complex glycerin-sulfonamide paste. Heggie, Gerrard and Heggie¹¹⁰ reported a number of sulfonamide emulsions. Sulfanilamide has been incorporated into a tannic acid jelly¹¹¹ and mixed with liquid petrolatum.¹¹² Allen and his co-workers¹¹³ believed a sulfathiazole ointment using a water in oil base to be of value. They advocated its use in the pressure dressing procedure of Koch in place of petrolatum. Colebrook¹¹⁴ proposed sprinkling sulfanilamide over the burned area and covering it with petrolatum gauze and warm saline dressings. The use of dry sulfonamides as a local measure with saline baths or hot wet dressings and the "tulle gras" procedure has been reported.

Not one of these methods for local application has supplanted in full the procedures discussed elsewhere in this report. The choice depends on individual experience and preference and adaptability to the local measures used. When used locally as a powder, sulfanilamide is preferred by many,¹¹⁵ while sulfathiazole and sulfadiazine jellies and ointments have their advocates.¹¹⁶ The only one to be reported as forming an eschar is sulfadiazine.⁷⁷ Regardless of these reports, more recent observations have shown that the ideal ointment or emulsion has yet to be devised. If these drugs are used locally, especially in such wide, denuded areas as occur in burns, the same precautions must be taken as are followed when the drugs are given by mouth. The blood picture and urine output are to be followed routinely.

Some investigators have advocated the routine use of one of the sulfonamides by mouth in all burn cases.¹¹⁷ While there might seem to be some advantages accruing from this procedure, it has been criticized on the basis that nausea and

vomiting are frequent and would further add to the hemoglobin concentration now recognized to occur in burns.¹¹⁸ Further, these drugs may aggravate or precipitate real or incipient liver damage.¹¹⁹ If oral administration is ordered, sulfadiazine and sulfathiazole have been the drugs of choice.¹²⁰

FIRST AID

If only reddening of the skin has resulted from the burn and the superficial (first degree) nature of the lesion can be definitely ascertained, the application of a soothing ointment may be allowed.¹²¹ When blistering or tissue destruction have occurred and hospital facilities are close at hand, most authorities are agreed that no local medication other than a covering of sterile dressings should be applied or, lacking that, a clean cloth of any nature.¹²²

If the burn is extensive (which some have estimated as 20 per cent of the body surface), anti-shock treatment is imperative and should include the administration of morphine and an avoidance of everything which might cause fluid or plasma loss or exudation. If hospital admission is delayed, the first intravenous plasma (solution of crystalloid substances such as dextrose or sodium chloride may be actually harmful) should be begun if at all practical;¹²³ 500 cc. may be given without waiting for blood studies. Greasy applications are avoided by many on the grounds that they produce only moderate alleviation of pain (a function better performed by morphine) and add to the difficulties of properly cleansing the burned area.¹²⁴ Oils and greases make necessary vigorous handling and the use of fat solvents, procedures which may precipitate or increase shock. Further, the presence of grease makes difficult the formation of an eschar. On receiving an emergency call the physician may advantageously warn his informant or the victim's helpful neighbors to put nothing on the wound before his arrival and, on learning of the severity of the case, have the hospital informed that an emergency room will be urgently needed.

If the patient cannot be transferred to a hospital for several hours (twelve to twenty-four) some form of local dressing may be necessary. Such dressings should aim at preventing external loss of fluid, relieving pain and preventing further contamination. Whatever the individual preference for local applications, shock treatment is even more imperative under these conditions than if a hospital is readily available.

SUMMARY AND CONCLUSIONS

A review of the literature brings out two basic principles which serve as guides to the proper local care of a burn. First, properly applied, many of the more established local measures may give good results if the systemic care of the patient is adequate. Second, gentle cleansing and no unnecessary débridement of the burned area is essential for the successful application of any of the local methods of burn therapy. Under certain conditions, as a life saving measure or the necessity of handling large numbers of cases in a short time, the preliminary cleansing may have to be shortened. If infections occur, prolonged healing time and poor functional results may ensue.

A pronounced change in medical opinion regarding the use of tannic acid and other tanning agents has become apparent. The possibility of disastrous results following the formation of an eschar should always be kept in mind when the burn area is on the face, hands or genitalia. If escharotics are used, those producing a thin, tough, flexible eschar rapidly are preferred by some, although those producing similar eschars more slowly may possess certain advantages, which will result in their selection in many cases.

For those areas where an escharotic is contraindicated, or for infected burns, a number of variations of the saline bath are available. Of these, the continuous saline bath, the Buñyan envelop and the tulle gras dressing have their advocates. They are usually used with the local application of a bacteriostatic agent, as one of the sulfonamides, electrolytic sodium hypochlorite or Dakin's solution.

The use of the pressure dressing as advocated by Koch reveals interesting possibilities and its use has become very popular.

The use of growth stimulating agents has not been adequately studied, and much work remains to be done in this field. None have been accepted by the Council on Pharmacy and Chemistry.

The widespread use of the sulfonamides, both locally and orally, marks a definite trend in the treatment of burns; they offer promise for the prevention and treatment of infection. However, prolonged use of these agents may cause sensitization. This is a danger that should be kept in mind by all physicians. In concluding this discussion it is well to point out that no method which has been presented to date makes the proper care of burns anything but a tedious and time consuming procedure, the results of which are frequently disappointing. The alternatives are clear: high mortality and morbidity, loss of function and disfigurement for the patient. The responsibility of any individual or group attending a burned patient is obvious. Further, one of the commonest errors in the treatment of burns is underestimating the extent and seriousness. All burns should be regarded as potentially serious wounds.

In no instance should local treatment replace the prevention and treatment of shock, prophylaxis against tetanus and possibly gas bacillus infections and proper surgical procedures when indicated.

The comparative evaluation of the various treatments proposed for burns would be made more accurate if proper records always were kept and published. Boyce⁶³ has stressed the inadequacy of most records. Harkins⁶ has posed four pertinent problems: 1. What is the longest possible interval after a burn that tanning therapy can be applied under optimum conditions? 2. What percentage of plasma loss does tanning prevent? 3. Assuming that the main purpose of the tanning method is to conserve plasma, if plenty of plasma is available, is tanning still advisable? 4. Is tannic acid toxic? At least one other may be proposed:¹²⁵ What is the best means of hastening the sloughing stage of deep burns, promote maximum healing and still prevent infection? Similar questions proposed by many authorities emphasize that more critical observations, well documented and controlled, are needed. In reporting results care should be taken to record the site, extent and depth of the burn, the incidence, degree and location of infection, the physiologic state of the patient as indicated by blood and urine studies and kidney and liver function tests, the nutritional state of the patient and his age. The effectiveness of newer antiseptic agents and their effect on the patient should be determined. Statistical evaluation would be desirable, and the utilization of proper controls should not be forgotten in investigational work.

ADDENDUM

Since the Councils' report was prepared, many other papers have appeared in print. Some of them represent much work and critical evaluation. For example, Drs. Roy D. McClure and Conrad R. Lam have offered a study of a survey representing the burns occurring in a group of approximately 250,000 industrial workers. After examining the data for tannic acid, greasy ointments, vitamin ointments and sulfonamide ointments they concluded that there were an unreasonable number of different preparations being used for the treatment of minor burns in industrial plants and that the average minor industrial burn is apt to be healed in less than a week. They suggested washing with white soap and water, no breaking of blisters or other debriding, a cover of fine mesh gauze impregnated with petrolatum or 5 per cent boric acid ointment and a firm dressing of sufficient size to keep away dirt.

More recently, there appeared in *THE JOURNAL* (June 24, July 1, 1944) a symposium of seven papers published under the auspices of the Section on Surgery, General and Abdominal. The authors discussed the problem of thermal burns, the chemical aspects of burn treatment, the general care of the burned patient, the present status of the tannic acid method in the treatment of burns, surgical cleanliness, compression and rest as primary surgical principles in the treatment of burns, the early plastic care of deep burns and the late plastic care of burn scars and deformities.

After a consideration of the other papers made available more recently, the Councils declared there was no need to change the report. In fact, most of the more critical presentations tend to support the principles set forth in this joint statement.

ESSENTIALITY OF AMINO ACIDS

Not long after the demonstration, on the basis of chemical analysis, that some proteins fail to provide certain amino acids, nutritional studies with experimental animals established that growth, maintenance and physiologic well being cannot be attained unless certain amino acids are available to the animal. Indeed, the work of Hopkins and of Osborne and Mendel in this connection served to turn attention from the importance of the quantity of protein in the diet to a consideration of the biologic significance of the quality of the food proteins as regards their amino acid content. The brilliant work of Rose and his collaborators at the University of Illinois has served not only to expand the number of amino acids recognized as indispensable for adequate nutrition but also to clarify the general concept of the nutritional significance of amino acids. At present it is generally accepted that there are ten amino acids essential for the growth of the young white rat, the laboratory test animal most widely used for this type of study, and satisfactory growth over a limited span of the early life of these animals has been observed when these ten amino acids represent the main source of nitrogen in the experimental diet. However, Lewis¹ has cautioned lest the attitude prevail that protein nutrition in general can henceforth be satisfied with only the recognized essential amino acids or that the rest of the protein molecule is nutritionally of little importance.

On the basis of recent investigation, certain factors appear to be important in influencing the essentiality of the amino acids. The age of the experimental animal is one of these. Whereas arginine is needed preformed in the diet of a young rat, Scull and Rosé² have shown that the adult animal of this species can synthesize this amino acid rapidly enough for maintenance needs. Again, on the basis of balance experiments it

has been indicated³ that fewer of the "essential" amino acids are needed for maintenance of adults than for growth of young rats. There arises the question as to whether different species of animals have different needs for amino acid. It has been shown⁴ that amino-acetic acid is required by the chick, whereas the mammal appears to be able to synthesize this amino acid with ease. Furthermore, using the maintenance of nitrogen balance as the criterion of indispensability, Rose and his associates⁵ have demonstrated that histidine, essential for growth of rats, is not needed by human subjects.

Another factor which must be considered in the metabolism of substances administered by mouth is the activity of intestinal bacteria. A recent observation by Martin⁶ may have an important bearing on the philosophy of essentiality of amino acids. He reported that young rats given a complete diet containing all the essential amino acids failed to grow if succinylsulfathiazole was added to the diet. Having taken into consideration the vitamins known to be synthesized by the bacteria in the intestine, the suggestion is made that a significant part of the nonessential amino acids is provided to the host organism by synthetic action of the intestinal bacteria; once these are rendered inactive by the sulfonamide drug, the real need of the host for preformed amino acids is disclosed. Although further work in this field is needed, it is already obvious that the concept of indispensability of any dietary constituent can be held only under well defined conditions. This view applies likewise in the field of therapeutics and so merits renewed attention in medicine.

TERMINOLOGY OF CORONARY DISEASE

Master¹ believes that the adoption of the term "coronary failure" to designate acute coronary seizures would lead to ambiguity and confusion. He would retain both terms "coronary occlusion" and "coronary insufficiency," since each represents an entity more or less readily distinguishable by the mode of onset, the symptoms and the characteristic electrocardiographic alteration. Coronary artery occlusion means sudden, complete obstruction of a coronary artery characterized clinically by an attack of severe and prolonged substernal pain, shock, impairment of the first heart sound, gallop rhythm, occasionally a pericardial rub, a fall in blood pressure, fever, leukocytosis and a rapid sedimentation rate. Acute coronary insufficiency indicates necrosis or infarction of the myocardium without com-

plete closure of a coronary artery. Pain and necrosis or infarction of the myocardium may be produced by severe or prolonged diminution in the coronary flow in the absence of coronary occlusion.

The major difference between coronary occlusion and coronary insufficiency is in the mode of onset. Coronary occlusion begins independently of outside influences such as effort and excitement; actually it is most common during rest or sleep. Coronary insufficiency, on the contrary, is due to a sudden inadequacy of coronary blood flow produced by a number of factors, such as unusual effort, emotion, acute hemorrhage, shock, tachycardia, heart failure and surgical operations. If either increased cardiac work or diminished coronary blood flow develops in the presence of coronary artery disease, the myocardium may become ischemic; if the precipitating factor persists, necrosis of the heart muscle may ensue. Unlike coronary occlusion, pain may be a minor symptom in coronary insufficiency and sometimes is obscured entirely by the condition causing the ischemia, for example, shock or surgical operation. The electrocardiogram is considered characteristic of acute coronary occlusion when elevation of the RS-T segment and a deep Q wave are present in one or more leads, with progressive change from RS-T elevation to T wave inversion in serial records. In acute coronary insufficiency the typical electrocardiographic changes consist of RS-T depression and T wave inversion in two or more leads. RS-T elevation and deep Q waves are absent. Unlike that in coronary occlusion, the electrocardiogram returns to its original configuration in several days or weeks.

The concepts that have been described were evaluated in a clinical, electrocardiographic and postmortem study of 100 consecutive cases in which the diagnosis of coronary occlusion had been contemplated. In 49 cases the electrocardiographic pattern was considered characteristic of coronary occlusion, and the latter was found post mortem in 47 of these. In addition, the electrocardiogram clearly indicated whether the infarction was anterior or posterior. Not every attack of coronary occlusion results in typical electrocardiographic alteration; this is true chiefly in multiple fatal attacks. When the electrocardiogram presents RS-T elevation and Q waves, the diagnosis of coronary occlusion is practically certain. Progressive RS-T depression or T wave inversion were present in 5 cases, and the necropsy revealed in all 5 cases coronary sclerosis without occlusion. Thus the authors were apparently able to differentiate coronary occlusion from coronary insufficiency in 95 per cent of their cases on clinical and electrocardiographic data.

Masters and his collaborators feel that the term "angina pectoris" should be retained because of its classic clinical picture. The syndrome is represented by the typical substernal pain and its radiation, its rela-

tion to effort, excitement, cold and eating and its relief by rest and glyceryl trinitrate. The term connotes one type of coronary insufficiency. It differs from the more severe forms of coronary insufficiency in that anatomic alterations do not occur in the cardiac muscle; the attack of pain is usually of short duration, shock is absent, the heart sounds and blood pressure are not significantly altered, and pericardial rub and heart failure do not appear. Fever, leukocytosis and an increase in the sedimentation rate are absent. Immediately after the attack the patient returns to his previous condition, that is, he may feel entirely well. The electrocardiogram is usually normal, but the changes characteristic of coronary insufficiency may appear transiently during the attack.

Current Comment

QUINACRINE (ATABRINE) IS SATISFACTORY IN MALARIA CONTROL

An official report from the Board for the Coordination of Malarial Studies on the use of atabrine in the prevention and treatment of malaria appears on page 977. It answers the questions which have been in the minds of many physicians relative to the comparative advantages and disadvantages of quinine, totaquine and quinacrine (atabrine). The postwar world, with the knowledge now available about this drug and on methods of malaria prevention, should be able to eliminate malaria from every civilized nation. That would be, indeed, a blessing derived from the most destructive and costly war the world has ever known.

EFFECTS OF VARIATIONS IN INTRACRANIAL PRESSURE

Experiments on variations in intracranial pressure reported by Kahn¹ were begun with the intention of studying the effect of experimentally produced cerebral edema on consciousness in the dog. Distilled water was perfused into the anatomic central end of the common carotid artery, and observations were made as to whether or not this would render the animals comatose. Records with the kymograph were taken simultaneously of the respiration, the general carotid blood pressure, the cerebrospinal fluid pressure in the cisterna magna and the pressure in the brain tissue. The assumption that the pressure in the lateral ventricles was being accurately recorded by measurement of the cisternal pressure was later demonstrated to be fallacious, so that the intraventricular pressure was simultaneously recorded thereafter with a mercury manometer. Kahn's studies indicate that the respiratory and circulatory embarrassment associated with high levels of intraventricular and intracerebral pressure may be relieved by ventricular drainage, which lowers both the intra-

1. Kahn, Alfred J.: Effects of Variations in Intracranial Pressure, *Arch. Neurol. & Psychiat.* 51: 508 (June) 1944.

ventricular and the intracerebral pressure. In experiments on otherwise normal animals in which the intraventricular pressure was abruptly raised to levels between 60 and 10 mm. of mercury below the diastolic blood pressure, accompanied by measures designed to keep the cisternal pressure low, the respiration became directly affected; it became depressed and inhibited more quickly in general at the higher pressures than at the lower pressures employed. The ill effects of increased intraventricular pressure (with low cisternal pressure) appeared to be due to the herniation of the medulla into the foramen magnum. This herniation was observed in dogs as a result of elevation of the intraventricular pressure while the cisterna magna was opened to the exterior. Ventricular drainage, together with artificial respiration and administration of isotonic solution of three chlorides infused into the central end of the common carotid artery, was efficacious in restoring respiration and increasing the blood pressure after severe medullary trauma in the water perfusion experiments in dogs. The fact that the experimentally produced state of high intraventricular and low cisternal pressure gives rise to dire respiratory and circulatory effects, which disappear when the disparity between the two pressures is reduced, appears to be clinically significant. Serious danger is involved in lumbar puncture when the possibility of a block between the ventricular reservoir and the subdural fluid spaces exists. Kahn believes that use of lumbar puncture as a means of relief of intracranial tension is contraindicated because of this danger when there is internal hydrocephalus subsequent to severe cranial trauma. Ventricular drainage is indicated and should be done as quickly as possible because of the damage to the medullary centers by prolonged tension.

INFLUENCE OF TEMPERATURE CHANGE ON ANGINA PECTORIS

Patients with angina pectoris commonly experience an increased frequency of attacks during cold weather. Now this response has been used as an aid in diagnosis and also for investigation of certain aspects of the disease. Patients were placed in a cold room, thereby precipitating an attack. In a recent investigation by Freedberg and his colleagues¹ 22 patients with angina pectoris due to coronary arteriosclerosis were studied. Local application of ice to the hand during exercise reduces the exercise tolerance of patients with angina pectoris and results in the precipitation of pain even when the patient is in a warm room. This observation parallels the experience of many patients with angina pectoris who, although warmly clothed and with only the face exposed, nevertheless have more attacks of pain in winter than in summer. The effect of local application of cold was extremely rapid; it could be demonstrated in ten seconds, reached a maximum in thirty to forty seconds after application and could not be

prevented by obliteration of the venous return from the area to which the cold was applied. The prior application of heat or the administration of nitroglycerin nullified this effect, however. The concept that coronary artery vasomotor changes, probably reflex in origin, exert a contributory influence in the precipitation of attacks of angina pectoris and that heat acts as a coronary vasodilator and cold as a vasoconstrictor or to prevent vasodilatation is supported by these results. The prophylactic use of heat enables many patients with angina pectoris to perform considerably more work in a cold atmosphere and suggests that the local application of heat may be of value in the prevention of attacks in daily life under certain circumstances. The local application of ice was reported to be a valuable clinical substitute for a cold room in precipitating attacks of angina pectoris for diagnostic or other investigative purposes.

ASCORBIC ACID LOSS IN MINCED SALADS

Recent studies² have shown that mincing speeds the rate of disappearance of ascorbic acid from fresh fruits and vegetables; enzymes, metallic catalysts and fine division apparently favor oxidation. In military service minced salads are often prepared several hours before serving, so that methods of preventing rapid loss of this essential vitamin are of strategic importance. McCay and his associates² of the National Naval Medical Center, Bethesda, Md., therefore undertook a study of the effects of variations in routinely used technics for mincing. Cabbage, cucumbers, tomatoes, lettuce and other salad vegetables were sliced or minced by three different technics. The first samples were thinly sliced with a plastic knife. Duplicate samples were similarly prepared with a steel knife. A third group of samples was put through the standard metallic "Buffalo chopper." Each sample of minced green peppers, for example, had an initial vitamin C content of 130 mg. per hundred grams. In the plastic sliced samples this fell to 87 mg. per hundred grams by the end of two hours, a 33 per cent loss in vitamin C. The rate of loss was twice as fast in control samples sliced with a steel knife, the ascorbic acid content falling to 53 mg. per hundred grams. The loss was even more rapid in samples minced in the metallic chopper, the two hour assay being only 31 mg. per hundred grams, a 75 per cent loss. Similar differences in the rate of disappearance of vitamin C were noted with all other vegetables. With radishes, for example, the two hour loss was 90 per cent of the initial ascorbic acid content when this vegetable was minced in the metallic chopper. The loss was but 30 per cent if it was sliced with the plastic knife. To minimize vitamin loss in military service, McCay believes that some form of plastic chopper should be devised and substituted for the present metallic grinder, and that wherever possible sliced or minced salads should not be prepared until just before serving.

MEDICINE AND THE WAR

QUINACRINE HYDROCHLORIDE (ATABRINE) FOR MALARIA

On May 31, 1944 the Board for the Coordination of Malarial Studies adopted the following resolution concerning the relative value to the armed forces of quinacrine hydrochloride, U. S. P. (atabrine), quinine and totaquine, U. S. P.

On the basis of controlled quantitative studies in civilian, Army and Navy establishments, the evidence at hand justifies the following statement:

1. *In the Suppressive Therapy.*—Quinacrine (atabrine) has proved to have all the antimalarial properties ascribed to quinine in the suppression of malaria during and subsequent to exposure to infected mosquitoes. Effective suppression can be accomplished over long periods of time by proper use of quinacrine. Available evidence indicates that this end may be achieved without danger to the individual.

Earlier reports indicated a significant incidence of gastrointestinal disturbances in certain groups of men receiving suppressive quinacrine therapy. For practical purposes these adverse reactions can be avoided by proper administration of the drug. Quinine, in doses adequate to assure suppression of malaria equivalent to that produced by quinacrine in the dosage currently used by the armed forces, is frequently attended by symptoms of cinchonism.

Quinacrine has been demonstrated to prevent consistently the development of falciparum malaria when the drug is administered in proper dosage before, during and after exposure.

2. *In the Therapy of the Acute Attack.*—Experience in the past two years has demonstrated conclusively that quinacrine (atabrine) when properly administered is fully as effective as quinine in the termination of the acute attack and is safer than quinine. The intramuscular injection of quinacrine is highly effective in securing a rapid therapeutic response. Evidence is not at hand to decide on the relative merits of quinacrine administered intramuscularly as compared with quinine administered intravenously in patients with fulminating cerebral malaria.

3. *In the Therapy of Vivax Malaria.*—Neither quinacrine nor quinine can be relied on to prevent relapses in vivax malaria following the discontinuation of therapy, although the interval between attacks is significantly longer following quinacrine than following quinine in the dosage schedules currently used by the armed forces.

4. *In the Therapy of Falciparum Malaria.*—There is convincing evidence that quinacrine not only suppresses the clinical symptoms of falciparum malaria but also cures this malignant form. The evidence of a similar curative effect of quinine is not conclusive.

5. *Totaquine (U. S. P.).*—Because of its content of crystallizable cinchona alkaloids, totaquine (U. S. P.) has activity which approximates that of quinine and therefore can be used as a substitute for quinine when given orally. The antimalarial activity of totaquine (U. S. P.) is dependent on the amount of crystallizable alkaloids in the preparation rather than on the specific amount of each individual alkaloid. Gastrointestinal disturbances occur more frequently following the use of the present totaquine (U. S. P.) than they do following the use of quinine or quinacrine.

On the basis of the foregoing statement, it is resolved:

1. That no advantage, and possible disadvantage, would accrue to the armed forces were quinine or totaquine to replace quinacrine for the routine suppression and treatment of malaria.

2. That the large scale production of quinine or totaquine is not now considered a matter of importance for the management of malaria among Army and Navy personnel. It is possible that a supply of totaquine in excess of the present stockpiles may be required for therapy in civilian populations temporarily under the jurisdiction of the armed forces in occupied territory where immediate dissemination of information concerning the use of quinacrine (atabrine) is not practicable. In this connection it should be kept in mind that after the war the overall need for all established antimalarial drugs will continue to be great.

BOARD FOR THE COORDINATION OF MALARIAL STUDIES, NATIONAL RESEARCH COUNCIL: R. F. Loeb, Chairman; W. M. Clark; R. G. Coatsy, U. S. P. H. S.; L. T. Coggeshall, Comdr. (MC), U.S.N.R.; F. R. Dieuaide, Lieut. Col., M. C., A. U. S.; A. R. Dochez, O. S. R. D.; E. G. Hakansson, Capt. (MC), U.S.N.; E. K. Marshall Jr.; O. R. McCoy, Major M. C., A. U. S.; F. T. Norris, Lieut. Comdr. (MC), U.S.N.; W. H. Sebrell, U. S. P. H. S.; J. A. Shannon, and G. A. Carden Jr., Secretary.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

UNITED STATES PUBLIC HEALTH SERVICE NEEDS PHYSICIANS

The U. S. Public Health Service needs 322 physicians immediately. About 170 of these are needed for assignment to duty in the War Shipping Administration, for foreign shore duty with the UNRRA and for sea duty and foreign shore duty in the U. S. Coast Guard. One hundred and fifty-two physicians are needed for duties in Hospital Division, Foreign Quarantine, Tuberculosis Control, Venereal Disease Control and other states relations work. The U. S. Public Health Service has asked that state chairmen be informed of these needs in order that available physicians may apply for reserve commissions.

INCREASE IN AREAS IN NEED OF PHYSICIANS

The first three months of 1944 show an increasing number of areas in need of physicians reported by state chairmen to the central office of the Procurement and Assignment Service. The rise in areas reported may reflect an increase in medical care needs or may be the result of improvement in reporting by state chairmen. Shortage reports are now being submitted

more regularly than in the past. It will not be possible to make comparisons and draw definite conclusions until complete returns are received each month from each state.

The record of medical care need for January is based on 41 current reports, on 47 for February and on 53 for March. The number of communities in need of physicians rose from 170 in January to 185 in February and to 199 in March. The number of physicians needed throughout the nation according to state chairmen was 225 in January and 232 in February and in March. Consistently the need has been for general practitioners, only 11 per cent of each month's total need being for specialists.

SANITARY CORPS OFFICERS NEEDED

A recent announcement by the Surgeon General of the Army indicates that there is need for a limited number of sanitary engineers, bacteriologists, biochemists and entomologists as commissioned officers. Eligible sanitary engineers will be cleared through the Procurement and Assignment Service with procedures similar to those in effect for the processing of physicians. Qualified specialists in these fields will receive ranks commensurate with their experience and ability.

ARMY

MALARIA IN THE ARMY

In the present war casualties from malaria have been an important factor influencing military operations in certain theaters of action. In overseas areas the total number of deaths directly attributable to malaria in 1943 was under 100. Patients who died usually had fever for only two or three days. The rates of the disease in highly malarious theaters are now but one fourth to one third of that which existed early in the war. Quinacrine has proved equal and in some ways superior to quinine for suppressing symptoms among troops operating under conditions where complete protection from malaria carrying mosquitoes is not possible. Individual preventive measures have been improved by the development of highly effective mosquito repellents and aerosol sprays. In this country as part of the army program an enormous mosquito control campaign was organized and carried out in 1941 at a cost of almost \$2,000,000. The malaria rate during that year not only failed to rise in the face of enormous increments to the military establishments but actually dropped to the low figure of 1.7 per thousand. In 1942, after the campaign had been intensified, the malaria rate for troops in this country decreased to 0.6 per thousand and in 1943 dropped still lower to 0.2 per thousand. The mosquito control program has effectively prevented malaria from becoming a problem among troops stationed in the United States.

ARMY AWARDS AND COMMENDATIONS

Captain Martin M. May

The Soldier's Medal was recently awarded to Capt. Martin M. May, formerly of Marion, Ill., who is now serving in the Army Medical Corps in Italy. The citation accompanying the award read "for heroism not involved in conflict with the enemy. On 7 June 1944 a fire of unknown origin started in the engineer combat battalion supply dump. The fire spread quickly through the inflammable materials in storage. Most of the men were trying to extinguish the conflagration when a tremendous explosion threw them to the ground, sending sheets of flame and smoke and bits of torn metal throughout the area. Twenty-four men and three officers were killed by the blast. As the smoke cleared away, Captain May saw Technician Fourth Grade Weibrich, severely burned, internally injured and suffering from shock, attempting to crawl out of the flaming arca. With complete disregard for his own life Captain May left his place of safety and with the help of an enlisted man ran into the flaming inferno and carried Weibrich out. Although there were still small explosions, and knowing that the fire might engulf the wounded man, Captain May courageously and heroically risked his own life in the face of known danger to rescue Technician Weibrich. Captain May then proceeded to organize his medical aid men and some volunteers to treat the casualties. He personally administered morphine and blood plasma to the most severely wounded. Unquestionably Captain May's prompt calculated actions saved the sight and the lives of several of the men. His heroic conduct is a credit to himself and to the Medical Corps." Dr. May graduated from St. Louis University School of Medicine in 1938 and entered the service Oct. 7, 1942.

AUSTRALIAN FLAG GIVEN AMERICAN
ARMY NURSES

An Australian flag has been donated to the Army Nurse Corps by a nurses' welfare association in Tasmania in appreciation of the work of American nurses in Australia. The flag was presented as a "link of friendship" by the Armed Services Nurses Welfare Association of Tasmania. The association requested that the flag be presented by the Australian delegate to the International Labor Conference in Philadelphia, and Col. Florence A. Blanchfield, superintendent of the Army Nurse Corps, designated Major Edna D. Umbach, principal chief nurse of the Valley Forge General Hospital, Phoenixville, Pa., to receive it. In a letter explaining the purpose of the gift, Miss Edith Ransom, state president of the Tasmanian nurse group, said its members wished to show "their appreciation of the work of the American nursing services in Australia."

BRONX AREA STATION HOSPITAL

The Bronx Area Station Hospital, New York, formerly the Lebanon Hospital, was formally dedicated on June 7. The hospital was taken over by the Army about a year ago and was originally intended for the use of women in the military services. The hospital's purpose has now been altered to care for transient army personnel within the area including upper Manhattan, the Bronx and Putnam and Westchester counties, west of the Bronx River and Taconic State Parkway. The hospital is an eleven story structure with a capacity of 200 beds. The staff includes eleven medical officers, six dental officers, three medical administrative officers, sixteen nurses, fifteen nurse's aides and a Red Cross staff of eighteen as well as Medical Department enlisted men and civilian employees.

ARMY MEDICAL LIBRARY STAFF CHANGE

A recent army regulation announced that the Army Medical Library, often referred to as the Surgeon General's Library, shall be administered by an officer of the Medical Corps with the title of Director. The Director is charged with the general administration, with upholding policies laid down by the Surgeon General, and representing the library before the public. A principal assistant to the Director with the title of Librarian may be either a commissioned officer or a civilian. "The Librarian shall possess a wide knowledge of and experience in library methods. Under the Director, he is charged with the coordination and technical operation of all elements of the Library."

Major Horace B. Dozier

Major Horace B. Dozier was presented with the Legion of Merit Award recently for exceptionally meritorious service in the North African Campaign. The citation read "For exceptionally meritorious conduct in the performance of outstanding services as hospitalization and evacuation officer from 21 March 1943 to 21 July 1943. During this period the base section supported the operation of the American forces in the Tunisian campaign. During the final phases of this campaign Major Dozier actively participated in the forward area by coordinating and supervising the evacuation of battle casualties. He assisted in the preparation and execution of the entire hospitalization and evacuation program. This program was so efficiently planned and executed that the evacuation of patients was effected with an absolute minimum of delay, even during the final phases when movements of large units were made with great rapidity, evacuation lines were long and communication facilities almost nonexistent. The efficient and capable manner in which Dozier carried on his duties played a great part in the excellent medical care which was provided for battle casualties." Dr. Dozier graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1939 and entered the service June 29, 1941.

Colonel Edward J. Kendricks

The Legion of Merit was awarded by the War Department to Col. Edward J. Kendricks, a regular army officer since Oct. 1, 1930, "for exceptionally meritorious conduct in the performance of outstanding service from September 1942 to October 1943." Dr. Kendricks graduated from Northwestern University Medical School, Chicago, in 1922.

Captain Seymour L. Osher

Capt. Seymour L. Osher, formerly of Maywood, Ill., was recently awarded the Bronze Star for heroic action in Italy. The award was for remaining at his post and performing surgery despite the fall of flak throughout the hospital. Dr. Osher graduated from the University of Illinois College of Medicine, Chicago, in 1940 and entered the service Feb. 20, 1942.

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

July 31, 1944.

Another Aspect of Medical Manpower Shortage

Another aspect of the nation's critical shortage of medical manpower is underscored in figures presented to a new national venereal disease committee appointed recently by Paul V. McNutt, Federal Security Administrator, to "plan new programs in the fight against venereal diseases and their spread." Although progress has been made in controlling incidence of venereal diseases in the Army and Navy "to the lowest point in history," there has been a slight current increase, from which the following factors were elicited: (1) increased reporting of infections with the advent of penicillin and the shorter period required for treatment, (2) shortage of trained venereal disease men in this country after the departure of more trained men for overseas duty and (3) the possibility of laxity induced by over-reliance on new methods of treatment.

Col. Thomas H. Sternberg, representing the Army, informed the committee of an upward trend in army venereal disease rates in continental United States to 30 per thousand as compared with the average rate of 26 per thousand over the past year. Comdr. W. H. Schwartz said that the navy rate for continental Europe showed a slight increase in the same period. Despite these trends, both the Army and the Navy reported substantial decreases in days lost because of venereal disease, attributed to the use of penicillin, reducing the time required for treatment.

The new committee is composed of fifteen, including representatives of private organizations, the Army and Navy, the Public Health Service and the Social Protection Division of the Federal Security Agency. The committee will seek greater community and national cooperation in venereal disease control with a view to maintaining gains made into the demobilization period.

The committee hopes to augment for the postwar period these cooperative efforts. It has been established that no man will return to civilian life from the armed forces with a venereal infection that has not been cured or rendered noninfectious. It is believed that the coming period is a strategic time to eradicate the venereal scourge, but there is danger of a psychologic letdown.

Members of the National Venereal Disease Committee are the Rt. Rev. Harold J. Carroll, assistant general secretary, National Catholic Welfare Conference; Dr. Belmont Farley, National Education Association, 1201 16th Street N.W., Washington, D. C.; Dr. T. K. Lawless, dermatologist and consultant, Providence Hospital, Chicago; Mrs. Mabel K. Staupers, executive secretary, National Association of Colored Graduate Nurses, 1790 Broadway, New York; John A. Sengstacks, president, Negro Publishers' Association, managing editor, Chicago Defender, Chicago; Bishop R. R. Wright Jr., executive director, Fraternal Council of Negro Churches, Wilberforce, Ohio; Dr. Mordecai Johnson, president, Howard University, Washington, D. C.; Dr. Heller, assistant surgeon, Division of Venereal Diseases, U. S. Public Health Service, Bethesda, Md.; Dr. William F. Snow, American Social Hygiene Association, New York; Dr. Alphonse M. Schwitalla S. J., St. Louis University School of Medicine; Colonel Sternberg, U. S. Army; Commander Schwartz, U. S. Navy; Felix J. Underwood, Mississippi State Board of Health, Jackson, Miss.; Ralph McGill, editor, Atlanta Constitution, Atlanta, Ga.; Watson B. Miller,

assistant administrator, FSA; Rev. Roswell Barnes, associate general secretary, Federal Council of the Churches of Christ in America, New York; Mark A. McCloskey, director, Office of Community War Services and Eliot Ness, director, Social Protection Division, CWS.

Egyptian Minister of Health Touring the United States

Since the Allied victory at El Alemein signaled a victorious trend in the war, Egypt has been able to give some thought to postwar problems. So declares His Excellency, Dr. W. A. W. Wakil, Egyptian minister of health, recently a delegate at the monetary conference, who after a brilliant social reception in the capital has been touring the United States in connection with his own comprehensive health program for his country. Scientifically modern in his views, Dr. Wakil has mapped out a progressive program for Egypt, whose health problem, largely centered in the villages of rural areas, offers some interesting comparisons with this country. His trip here is nonpolitical and of a purely scientific and medical nature, and he is studying health, sanitation and hygiene methods, especially in our rural areas where the climatic conditions are nearest those in Egypt. Indicative of his outlook is his warning, well publicized in the daily press, that air traffic has increased the spread of communicable diseases. He advocates an international health conference to be held within two or three months to set up prevention measures to combat transport of diseased persons, bacteria and insects by airplane. As an illustration, he says the Gambia mosquito was brought to Egypt for the first time via plane and cases of malaria have resulted. In this connection Dr. Wakil proposes to study quarantine methods in the aviation center at Miami.

Basic factor in the overall health problem in Egypt, he says, is an exceptionally high birth rate. The rapid growth of population, unaccompanied by a parallel increase of national resources, is affecting public health through increased poverty, more overcrowding and more nuisances both in villages and in the poorer quarters of cities. The majority of Egyptians are employed in agriculture, with only some 700,000 persons, about 4 per cent of the population, employed in medium and large factories.

Dr. Wakil lists, as the principal health problems of Egypt, defective rural sanitation and welfare, paucity of pure water supplies in villages and high incidence of Bilharzia and Ancylostoma, high child mortality, incomplete campaigns against tuberculosis, venereal disease and leprosy, deficient hospitalization of the sick and defective urban sanitation. To meet them he advocates a five or ten year plan. He offers the following postwar health projects to deal with these problems:

1. Rural health reform: A. Generalization of pure water supplies. B. Generalization of rural health centers (for every 15,000). C. Eradication of Bilharzia and Ancylostoma. D. Village reconstruction by (a) radical methods, e. g. (1) construction of new villages, or (2) gradual village planning and sanitation. E. Abolition of remaining ponds and marshes.

2. Urban health reform: A. Generalization of drainage schemes. B. Generalization of urban health centers (for every 30,000).

3. Miscellaneous: A. Provision of more facilities for general and special hospitalization and treatment of the sick. B. Completion of the antituberculosis scheme. C. Completion of the antileprosy scheme. D. Introduction of more decentralization in the health administration. E. Provision of more medical and auxiliary staff.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

Norman Baker Released from Prison.—Norman Baker, former operator of alleged "cancer cure" hospitals at Muscatine, Iowa, and Eureka Springs, Ark., was to be released from the Leavenworth Federal Penitentiary July 19, newspapers reported. Baker was convicted at Little Rock in January 1940 on a charge of using the mails to defraud in the advertisement of a cancer treatment and was sentenced to four years in prison and fined \$4,000. He began serving the sentence in March 1941.

COLORADO

Personal.—Dr. Guy E. Calonge has been named a member of the La Junta School Board.—Dr. and Mrs. Thomas J. Jones, Hooper, observed their fiftieth wedding anniversary, June 6.

Rheumatic Fever Control Program.—The public policy committee of the Colorado State Medical Society recently rejected a proposed plan for rheumatic fever control in metropolitan Denver submitted by the state board of health and offered, instead, an alternate plan. Under the state board's plan the source of funds to finance the project would be an allotment of \$20,000 by the U. S. Children's Bureau, a grant of \$10,000 from the Denver War Chest for a diagnostic clinic, and available resources of existing hospitals wishing to participate. Administration would be by the state board and the participating hospital, the diagnostic clinic to be established at hospitals approved by the Medical Society of the City and County of Denver. Certain regulations were stipulated for basic professional services, plans for providing care, transportation facilities, education and mental hygiene, the last to be covered by the Child Guidance Clinic of the Colorado Psychopathic Hospital. The public policy committee of the state medical society submitted the following recommendations as signposts of policy for setting up the program, believing they will assist in avoiding the dangers of "bureaucratic sovietized medicine" and lead to a "noncompulsive, democratic program of sane public health":

1. The development of a statewide, rather than a local, cooperative rheumatic fever control program to be financed by such federal funds as are now available from the United States Children's Bureau and by any other funds available through appropriations from the Colorado state legislature or by Community Chest grants or private contributions.
2. The strict administration and supervision of this program by the Colorado State Board of Health.
3. The diagnostic and treatment aspects of the program to be carried out entirely and exclusively in private hospitals accredited by the American College of Surgeons and in convalescent homes approved by the Colorado State Board of Health.
4. The actual clinical work of the program, in both its diagnostic and its therapeutic aspects, to be performed entirely by physicians in private practice working on a part time basis and at a rate of compensation comparable to that prevailing in their various specialties in their particular communities.
5. The physicians employed to carry out the clinical part of the program to be their various fields of medical practice (pediatric surgery, psychiatry, neurology, etc.) by their specialty boards. However, in those rural districts where specialists are not readily available it is recommended that the state board of health be permitted to waive specialty requirements.
6. The nursing care to be provided by the nursing staffs of the participating hospitals—by school nurses—by nurses from accredited visiting nurses' associations and by the division of public health nursing of the Colorado State Board of Health.
7. The social work of the program to be provided by the social service staffs of those participating hospitals equipped with social service departments and by the Colorado State Board of Health.
8. The educational needs of the children treated under this program to be provided by existing private and public school teaching, vocational training and recreational facilities.
9. The follow-up care of the children treated to be under the joint supervision of the participating hospitals and the Colorado State Board of Health.
10. The mental hygiene aspects of the program to be directed by psychiatrists and neuropsychiatrists in private practice working on a part time basis in and through the various participating private hospitals or in their own private offices.
11. The program to be strictly limited to the diagnosis and treatment of acutely ill, financially eligible children properly referred to the Colorado State Board of Health by private physicians or accredited hospitals and health agencies.
12. Financial eligibility for free care under this program to be determined, in each case, by the Colorado State Board of Health in accordance with established standards for free medical care in Colorado.

ILLINOIS

New Chairman of Public Health Committee.—Benjamin Wham, Winnetka, has been appointed chairman of the Illinois Statewide Public Health Committee to succeed Frederic C. Woodward, LL.D., Chicago, resigned.

Physicians Honored.—The Saline County Medical Society held a dinner June 23 in Eldorado in honor of Drs. William T. Johnson, Eldorado; Joseph V. Capel, Harrisburg, and William D. Harrell, Norris City, who have completed fifty years in the practice of medicine and who have been awarded membership in the "fifty year club" of the state medical society.

Chicago

Personal.—Dr. Benjamin J. Feinstein was to retire July 31 as a police surgeon, after holding the position for twenty-seven years.

Psychiatric Clinic for Discharged Service Men.—The Illinois Society for Mental Hygiene announces the establishment of a psychiatric clinic in Chicago for service men discharged for psychiatric disorders. The clinic, which began July 18, will be open one evening a week in the former Washington Boulevard Hospital at 2449 West Washington Street. In the fall the services will be increased. The staff will include psychiatrists, psychologists and psychiatric social workers. It is hoped that similar clinics may be created throughout the state.

INDIANA

Activities at Indiana University.—In a recent statement to the board of trustees of the university, Dr. Willis D. Gatch, dean of the Indiana University School of Medicine, Indianapolis, stated that his division "has thrived on adversity," now having enrolled 313 medical students, 300 nurses, 14 laboratory technicians and 21 dietitians. Dr. Gatch stated that military discipline had been good for the students, having taught them to respect authority, to be punctual and to work. Students who fail at the end of the semester are not allowed to repeat the work and must leave school at once. Dr. Gatch stated that few failures had occurred except in the freshman year. In carrying out the program of the school, Dr. Gatch stated that one change affecting the curriculum was "the cutting away of obsolete and worthless material" and the reduction of the amount of work given in the specialties to that which a general practitioner needs to know. The students have been brought as much as possible into direct contact with the patients and have been made responsible for their own education. A resident clerkship procedure, inaugurated last year for an experimental period, was made effective in May of this year. This program includes an arrangement whereby each senior spends one semester as a resident clerk in the university hospitals or at Indianapolis City Hospital. Tentative postwar plans include the establishment in association with the Indiana State Board of Health of a school of public health, creation of extension courses of graduate medical instruction for hospital staffs and continuation of research activities.

KENTUCKY

Personal.—Dr. Milton Lopez Henriques, director of local health services for the Ministry of Health of Venezuela, is spending two months with the state health department in Kentucky under the auspices of the Rockefeller Foundation, according to the *Kentucky Medical Journal*.

Changes in Health Officers.—Dr. Jacob Leland Tanner has resigned as health officer of Mercer County, effective July 1, to reenter the private practice of medicine in Henderson.—Dr. Donald B. Thurber has resigned as director of the tricounty health department, Carrollton. Dr. Thurber, who will go to Paris to hold a similar position in Bourbon and Scott counties, will be succeeded by Dr. Mildred E. Burton, Gabbard, who is being transferred from the Owsley County Department of Health, Booneville. Dr. Thurber will succeed P. A. Surg. George M. Jewell, U. S. Public Health Service Reserve, at the Paris unit.

Dr. Howard Honored for Legislative Work.—Dr. Carl C. Howard, Glasgow, was honored at a public celebration at the Glasgow Country Club, July 13, for his efforts as chairman of the planning committee of the Kentucky State Medical Association in urging the passage of legislation creating six districts for tuberculosis hospitals in the state. The bill, appropriating funds for construction of the hospitals, passed

both houses of the general assembly unanimously and Dr. Howard is credited with having worked untiringly in bringing this about. Included among those at the celebration were the officers of the state medical association and the Barren County Medical Society, the state health commissioner, the lieutenant governor, a state senator and three members of the house of representatives.

MARYLAND

Occupational Disease Amendment.—The Maryland State Department of Health and the Baltimore City Health Department recently amended its occupational disease regulation governing limits for toxic materials. The change provides that exposures to dusts, fumes, mists, vapors, gases or any materials that may affect health shall be kept below certain stipulated limits.

MASSACHUSETTS

Personal.—Dr. Claire W. Twinam, formerly acting medical superintendent of the Lakeville State Sanatorium, Middleboro, has been appointed to succeed Dr. Carl C. MacCorison as medical superintendent of the North Reading State Sanatorium, North Wilmington.—Dr. Emma M. Varnerin, formerly connected with the Boston Red Cross Blood Donor Center, is now assistant district health officer in Boston for the state department of public health.

Commitment to Penal or Mental Institutions Figure in Licensure.—At a meeting of the Massachusetts Board of Registration in Medicine May 17 it was voted unanimously that it shall be the policy of the board, following a hearing, to revoke or suspend as the case may be the registration of any physician who has been sentenced to a penal institution. The same action applies to the registration of any physician who has been committed to and not yet discharged from a mental hospital.

New Professorship of Nutrition at Tufts.—The selection of a professor of nutrition at Tufts College Medical School, Boston, is now being considered. Last year Tufts established a fund in the medical school to commemorate the seventieth birthday of Miss Frances Stern, chief of the food clinic of the Boston Dispensary, Boston (*THE JOURNAL*, July 31, 1943, p. 958). The fund was to be used by Miss Stern to extend the research and educational activities of the clinic. Recently the Frances Stern Committee on Nutrition was created, and one of its first actions was to approve the selection of a full professor of nutrition and to recommend a survey by members of the Tufts faculty who have included nutrition in their courses of the past practices and suggested future ones. The Charles Hood Dairy Foundation, a local group, has voted to contribute half the amount annually for three years that the nutrition committee believes would be needed to begin the project.

MINNESOTA

Kenny Technic Included in Continuation Course.—The University of Minnesota Center for Continuation Study Course sponsored a week's study in the management of infantile paralysis June 19-24, which was the first in a new series to include demonstrations of the Kenny technic and presentations on certain clinical and investigative aspects of the problem of poliomyelitis. A special faculty for the first course included Dr. Kenneth F. Macey, Johns Hopkins University School of Hygiene and Public Health, Baltimore; Dr. Joseph Moldaver, Neurological Institute, New York; Dr. Donald Y. Solandt, University of Toronto, Canada; Dr. Robert Ward, Yale University School of Medicine, New Haven, Dr. Arthur L. Watkins, Massachusetts General Hospital, Boston, and Dr. Abe B. Baker, Berry Campbell, Ph.D., Dr. Wallace H. Cole, Dr. Ernst Gellhorn, Dr. Miland E. Knapp, Dr. John F. M. Pohl, Dr. Lewis Sher, Dr. Harry G. Wood and Sister Elizabeth Kenny of the University of Minnesota. The investigative and Kenny training programs of the University of Minnesota are sponsored by the National Foundation for Infantile Paralysis. Additional information may be obtained about future courses from Dr. William A. O'Brien, University of Minnesota, Minneapolis 14.

MISSOURI

Personal.—Dr. Frank J. Tainter, St. Louis, will serve as college physician at Lindenwood College, St. Charles, for the remainder of the school term, taking the place of Dr. Eugene J. Cnty, St. Charles, who is entering military service.

NEBRASKA

State Medical Election.—Dr. Charles McM Martin, Omaha, was chosen president-elect of the Nebraska State Medical Association at its recent annual meeting; Dr. Floyd L. Rogers, Lincoln, is president. Drs. William J. Reeder, Cedar Rapids, and William J. Gentry, Gering, are vice presidents, Dr. Roy B. Adams, Lincoln, is secretary and Mr. M. C. Smith executive secretary. The next annual session will be held in Lincoln.

NEW HAMPSHIRE

Statewide Tuberculosis Register.—The *Bulletin* of the National Tuberculosis Association announced that New Hampshire has been chosen as the first state in which a statewide register is to be undertaken. New Hampshire was selected because of the state's small case load, limited area and unified control of tuberculosis activities. The bulletin states that if, after suitable trial, a statewide register proves to operate satisfactorily in New Hampshire, plans will be made to extend this type of register to larger states where the problem is much more complicated.

NEW JERSEY

Fifty Years of Medicine.—The Middlesex County Medical Society gave a dinner June 21 in honor of six physicians who had completed fifty or more years in the practice of medicine. Dr. Henry Haywood, New Brunswick, was toastmaster and the guests of honor were:

Dr. Grover T. Applegate, New Brunswick, sixty years in practice.
Dr. John L. Lund, Perth Amboy, fifty two years in practice.
Dr. Charles B. Burnett, South River, fifty one years in practice.
Dr. Ira T. Spencer, Woodbridge, fifty one years in practice.
Dr. George W. Tyrrell, Perth Amboy, fifty one years in practice.
Dr. Frank C. Henry Sr., Perth Amboy, fifty years in practice.

State Board Upheld on Granting of Licenses.—The practice of the New Jersey State Board of Medical Examiners in granting licenses only to graduates of medical schools accredited by the American Medical Association was upheld July 18 by the state supreme court, the *New York Times* reported. The court had been petitioned by Dr. Albert Seymour Rothseid, Lawrence, Mass., to compel the board to grant him a license to practice medicine and surgery in New Jersey. The board had denied Rothseid a license on the basis that the Middlesex University School of Medicine of Massachusetts, from which he was graduated in the winter of 1943, was not accredited by the American Medical Association and therefore was not on the approved list of the board. Rothseid's argument was said to be that the action of the board in accepting the grading of medical schools of the American Medical Association without using its own judgment or discretion constitutes an unlawful delegation of its duty and power. In rendering an opinion, Justice Newton H. Porter said, according to the *Times*, "We think not. It is entirely within its discretion, it appears to us, to adopt the standard and grading of an organization of which it has knowledge and confidence." Rothseid, son of Dr. Abraham Rothseid, Newark, has a license to practice medicine in Massachusetts and is a member of the staff of the Lawrence General Hospital, Lawrence, Mass.

Defense Council Functions as Disaster Unit.—The Newark Defense Council, originally set up as an air raid emergency council, now functions as a community disaster unit and is planned to work in close cooperation with the American Red Cross. In the event of a catastrophe there are three dispatching points in the city, the Emergency Medical Service Control Center, the Newark Beth Israel Hospital and the Columbus Hospital, from which emergency medical service units are dispatched. Each unit consists of nurses, a first aider, a nurses' aide, an attendant and a motor corps driver. The casualties are given first aid and if necessary are taken to the nearest hospital or casualty station. There are nine cooperating hospitals, five reserve hospitals and seven casualty stations which would be activated and manned in an emergency. During an emergency the hospitals report to the central control office, stating the number of beds and personnel available. Regular incident rehearsals are held each month. Medical observers witness each incident and report any faulty action. Dr. Joseph A. Clarken is director of the emergency medical service. Dr. Lester W. Eisenstadt is coordinator of hospitals. Other units function under specially appointed supervisors while the general personnel, who are fingerprinted and equipped with identification cards, armbands, gas masks and steel helmets, include 212 physicians classified under their specialties, 282 registered nurses, 530 student nurses, 66 practical nurses, 375 Red Cross nurses' aides, 59 first aiders, 13 Red Cross motor corps ambulance drivers, 12 hospital superintendents and 408 attendants.

NEW YORK

State Plans Free Plasma Distribution.—The state health department is working on a plan to develop a program to make whole blood, blood plasma and other derivatives available for civilians throughout the state, the *New York Times* reported July 14. Dr. John B. Alsever, U. S. Public Health Service, who is in charge of the Office of Civilian Defense plasma reserve program, has been lent to the health department to help it develop a distribution program. The plan recently inaugurated in Michigan is now being studied by the New York department (*THE JOURNAL*, April 1, p. 1000). The *Times* stated that about twenty hospitals in New York have been cooperating with the Office of Civilian Defense to meet emergency needs and that a number of other hospitals have maintained blood banks to handle possible disasters in larger centers. The value of this plan is too great to be limited and should be extended to other sections of the state, it was said.

New York City

Personal.—Dr. Jacob Sacks, formerly assistant professor of pharmacology, University of Michigan Medical School, Ann Arbor, has been appointed director of the pharmacologic laboratory of Endo Products, Inc., Richmond Hill.

Penicillin Free to Hospital Service Members.—Penicillin will hereafter be provided where necessary without charge to the hospitalized members of Associated Hospital Service using semiprivate and ward accommodations in 260 hospitals of the New York area. A special reserve fund is to be set up to reimburse hospitals for additional costs due to this and other unusual remedies required for the treatment of Associated Hospital Service members.

Noncommercial Drug Exhibit.—The New York Academy of Medicine has set up plans for a continuous noncommercial drug exhibit at its headquarters. The exhibit will be in charge of a physicians' committee on drug exhibits which will work with an advisory committee of drug manufacturers. Dr. Theodore G. Klumpp, president of Winthrop Chemical Company, Reusselaer, N. Y., is chairman of the advisory committee. A person will be in charge of the exhibit who will be able to answer questions and explain new drugs, and pamphlets and literature will be furnished, giving the research and clinical usage and describing the products.

Fluorine and Dental Caries.—The New York Institute of Clinical Oral Pathology will devote its first open meeting at the New York Academy of Medicine, October 30, to a symposium on fluorine and dental caries. Additional information may be obtained from Mr. G. Roistacher, executive secretary of the institute, 101 East 79th Street, New York. The institute was incorporated in New York on Dec. 20, 1932, organized for the study and advancement of oral pathology, particularly of the correlation of clinical findings, x-ray examination and histopathologic evidence. Dr. Raymond Gettinger, Brooklyn, is pathologist of the laboratory. Said to be the first of its kind, the institute's physical equipment began with the presentation by Dr. Theodor Blum of his medical laboratory with all specimens and apparatus.

OKLAHOMA

Physician Gives \$100,000 to Orphan's Home.—Dr. and Mrs. Silas G. Hamm, Haskell, have given property and other considerations approximating \$100,000 to the Tipton Orphan's Home of the Church of Christ. The gift will make possible the construction of three new buildings out of the six planned by the home.

Personal.—Dr. Elmer E. Goodrich, Crescent, has been named health officer of Chickasha and Grady County.—Dr. John F. Hackler, Oklahoma City, director, technical field unit, Oklahoma State Department of Public Health, has been appointed professor of hygiene and public health at the University of Oklahoma School of Medicine, Oklahoma City.

State Society Plans New Library.—The council of the Oklahoma State Medical Association recently approved the installation of a new council room and library in the office of the state association. The library will be set up with the idea of supplying complete information on the subject covered by membership committees.

The Dr. M. L. Perry Scholarship.—Dr. John C. Perry, Tulsa, has established an annual scholarship for premedical students at the University of Tulsa, to be known as the Dr. M. L. Perry Scholarship in honor of the late Dr. Marcus L. Perry, Tulsa, father of Dr. John C. Perry. Selection of the winner of the scholarship will be based on the contestant's past scholastic record, medical aptitude, character and financial need.

Plan for Health Education.—A program for health education will be launched in Oklahoma during the coming school year under the auspices of the state superintendent of public instruction, the state health commissioner and members of their respective staffs. As a preliminary step in the development of its program, workshops in health education were conducted in four centers from June 12 to June 23: Northeastern State College, Tahlequah, East Central State College, Ada; Southwestern Institute of Technology at Weatherford and for Negroes at Langston University, Langston. The workshops were designed for superintendents, principals, teachers, directors of physical education, public health personnel, other professional personnel and lay persons in general who may be interested in promoting individual and community health. Special attention was given during these workshops to the formation of committees to outline a syllabus and other materials necessary to the success of the state plan for health education, which, it is hoped, will make for better relationships in health education between school and community.

VIRGINIA

Changes in the Staff at Medical College of Virginia.—Promotions on the staff of the Medical College of Virginia, Richmond, effective July 1, include the following:

Sumter S. Arnim, D.D.S., to associate professor of operative dentistry and pathology.

John C. Forbes, Ph.D., to research professor of biochemistry.

Dr. Emmett T. Gatewood to clinical professor of otology, laryngology and rhinology.

Dr. John S. Howe to professor of pathology.

Karl L. Kaufman, Ph.D., to associate professor of pharmacognosy.

Dr. Emanuel U. Wallerstein to professor of clinical otology, laryngology and rhinology.

Personal.—Dr. Walter L. Barnes, Petersburg, has been appointed coroner to succeed Dr. Elisha L. McGill, who resigned after holding the position since 1919.—Dr. Carl W. White has been appointed medical superintendent of the Lynchburg State Colony, Colony, succeeding Dr. George B. Arnold resigned.—Dr. William E. Brown, for twenty-three years medical director and superintendent of the Blue Ridge Sanatorium, Charlottesville, has resigned because of ill health. He has been succeeded by Dr. Frank B. Stafford, assistant superintendent since 1920.—Nelson Podolnick, assistant surgeon, U. S. Public Health Service Reserve, has been appointed health director for the health departments of Fairfax, Prince William and Stafford counties.

WASHINGTON

Advisory Committee Named for State Department of Health.—The board of trustees of the state medical association has approved the appointment of an advisory committee to the state department of health to be composed of the chairman of the following committees: industrial hygiene, maternal and child welfare, neoplastic, public health and sanitation, public laws, public relations, social hygiene, tuberculosis and mental hygiene.

Establishment of Blood Bank Approved.—The establishment of a statewide blood bank under the auspices of the state department of health, the state medical association and the county medical societies has been approved. Funds have been obtained with the understanding that it will be lent for use in blood bank areas. Medical societies within such major areas will control the bank with the understanding that hospitals will not be permitted to make a profit from it. The blood and plasma will be sold at a reasonable cost to maintain the bank. The plan will work in with the civilian defense banks now in existence, thereby utilizing stock now on hand and replacing it continuously within a sixteen day period, after which it will be converted into plasma.

WISCONSIN

State Director Named for Infantile Paralysis Program.—Mr. Palmer F. Daugs, Lakemills, chairman of the Jefferson County chapter of the National Foundation for Infantile Paralysis, has been appointed state representative to direct the program of the National Foundation in Wisconsin. Mr. Daugs will act as coordinator between the National Foundation and the seventy-one county chapters.

Stanley Seeger Honored.—The amphitheater of the Milwaukee Children's Hospital has been named in honor of Dr. Stanley J. Seeger, Texarkana, Texas, vice president of the American Medical Association and formerly chief of staff of the hospital. The amphitheater was erected largely through the efforts of Dr. Seeger while in service at the hospital. On June 8 a plaque was unveiled in the amphitheater during ceremonies attended by Dr. Seeger, and the room was dedicated to bear his name.

GENERAL

Dr. Kelly Resigns as Secretary of Pharmaceutical Group.—E. F. Kelly, Phar.D., since 1926 secretary of the American Pharmaceutical Association, has resigned. A successor has not been named.

New Hospital Library Group Formed.—The Special Libraries Association formed a new national Group of Hospital and Nurses' Librarians within its organization during its annual conference, June 19-21, in Philadelphia, as a result of a petition submitted by hospital librarians. Miss Ruth Tews, head of the hospital library service of the St. Paul Public Library, was appointed chairman. The new group will give all librarians working in hospitals opportunity for active participation in the national development of their work, in the determining of standards, in the consideration of publications and in general extension of their services. Those interested in receiving the first News Letter of the new group should communicate with Miss Tews, Hospital Service, St. Paul Public Library, St. Paul 2, Minn.

National Medical Association.—The fiftieth annual convention of the National Medical Association will be held at the Sumner High School, St. Louis, August 14-17, under the presidency of Dr. Thomas M. Smith, Chicago. Included among the speakers will be:

Dr. John W. Lawlah, Washington, D. C., Supply and Demand of Negro Physicians as Related to Present War Emergency.

Dr. Harvey N. Middleton, Indianapolis, Diagnosis and Prognosis of Bundle Branch Block.

Dr. Herbert J. Erwin Jr., St. Louis, A Report of 100 Cases of Fever Therapy in Neurosyphilis.

Dr. Leonidas H. Berry, Chicago, Value and Mechanism of Certain Drugs in Gastrointestinal Disorders.

Dr. Charles R. Merry, St. Louis, Recent Advances in the Treatment of Burns.

The preliminary program includes many other speakers and representatives of the armed services. Dr. George A. Moore, Roanoke, Va., will discuss "Socialized Medicine" at the general closing session. On August 15 Dr. Charles R. Drew, Washington, D. C., winner of the 1944 Spingarn Medal (THE JOURNAL, April 22, p. 1212) will deliver the fourth annual oration in surgery, on "The Evolution of the Plasma Bank."

Incidence of Poliomyelitis and Other Diseases.—Four hundred and eighty cases of poliomyelitis were recorded during June for the country as a whole, according to a release from the Office of War Information, July 17, issued for the U. S. Public Health Service, Federal Security Agency. One hundred and thirty occurred in North Carolina, where the outbreak is localized in west central counties of the state and 55 in Kentucky. No other states have reported figures above normal expectancy. Scarlet fever totals remained at epidemic levels in June, reports for the month showing 11,000 cases as compared with 8,400 in June 1943 and about the same number for normal expectancy. Weekly figures for the month indicated a drop from an estimated 3,000 cases in the first week of June to half that figure in the last week. June, with a total of 113 reported cases of Rocky Mountain spotted fever, was high month for that disease; 61 cases occurred in the South Atlantic states with half of that number reported in Maryland and Virginia. On a nation wide basis, the total cases of Rocky Mountain spotted fever last month exceeded the June 1943 figures by twenty. The total of 170 cases reported in the first half of this year were approximately 20 less than in the same period of 1943. Although still epidemic, meningococcal meningitis is now in its seasonal decline. Totals for the June record 1,100 cases against 1,500 for the same period of last year. The disease has been epidemic for the past two years, according to the report, with high rates in the winter months and recessions in the summer.

LATIN AMERICA

Health Activities in Latin America.—Disbursement of Health Funds.—A total of \$1,130,000 has been allotted to the Puerto Rico Department of Health for the development of public and maternal health programs. Distribution of the fund will include \$68,000 for the federal program of crippled children, maternal and child care service, \$200,000 for the anti-venereal program, \$315,000 for public health, \$40,000 for social work and \$282,000 for title VI of the Social Security Program. Puerto Rico will provide \$40,000 for crippled children, \$100,000 for maternal and child care, \$75,000 for the anti-venereal program and \$10,000 for social service.

Typhus Situation Serious.—The recent increase in typhus in San Juan constituted "near epidemic proportions," according to the department of health of Puerto Rico. An average of 12 cases a month were reported from January through May

of this year, while at the end of the first seventeen days of June 19 cases had been reported. It was hoped that the "clean up campaign," which was begun June 18, would assist in improvement of sanitary conditions in San Juan.

Funds for Nursing Care.—The insular emergency council of Puerto Rico has approved the employment of 130 public health nurses at \$1,200 a year each, for twelve months starting July 1. An appropriation of \$156,000 was approved from war emergency program funds to pay the salaries. The council also approved the use of \$35,340 at the School of Tropical Medicine to solve the nursing crisis and an additional \$19,008 to meet the requirements of the minimum wage law for unskilled hospital personnel at the University Hospital of the School of Tropical Medicine.

New Construction.—Other projects approved by the insular emergency council of Puerto Rico included the construction of a two story concrete hospital building at Cayey to cost \$100,000 and improvements to the Municipal Hospital, poor asylum and city hall building at Mayaguez.

Lottery Funds Used for Tuberculosis Work.—A total of \$17,512,710 derived from the "insular lottery" in Puerto Rico has been expended into a ten year period as follows: for tuberculosis hospitals and other expenditures in the antituberculosis campaign, \$4,878,958.31; for second and third class municipalities, \$2,482,721.03 for welfare services; for charity district hospitals, \$2,311,753.66, for maintenance and operations of these hospitals.

Regulation on Hospital Admission of Patients.—A new regulation has been approved in Puerto Rico providing that admission of patients to the various services in the district hospitals shall be in accordance with a system of quotas for services in which there shall be assigned to each municipality a number of beds proportional to the number of inhabitants of each municipality, less the number of beds for hospitalization which the corresponding medical service of each municipality may have. The regulation provides further that a reserve of 40 unassigned beds shall be made in each hospital for emergency and isolation cases. Further provisions cover the applications for admission and the investigation of qualifications for admission. Persons whose annual income is not greater than \$1,000 in case they have dependents, and \$500 if they have not, shall be considered as deserving persons. Except in cases of emergency hospitalization, all admissions to hospital shall be made through the dispensary of the hospital.

Society of Kellogg Fellows.—The organization of the Society of Kellogg Fellows was recently announced. Named in honor of the founder of the Kellogg Foundation, the society aims to stimulate professional and educational activities of Latin American ophthalmologists. Dr. Harry S. Gradle, Chicago, was chosen honorary president. Members of the society are all Latin American ophthalmologists who have carried on postgraduate studies in their specialty through the aid of the W. K. Kellogg Foundation and the Pan American Congress of Ophthalmology. Members of the organizing committee are Drs. Daniel Silva, Mexico, Agustin Perret, Venezuela, and Manoel A. da Silva, Brazil. The final steps to complete the organization will be taken during the annual meeting of the American Academy of Ophthalmology and Otolaryngology in Chicago, October 8-12. *Ophthalmologia Ibero-Americana* has been designated the official journal of the society.

Special Society Elections.—Dr. Antonio Cândido de Camargo was elected president of the Associação Paulista de Combate ao Cancer for 1944. Drs. Luiz do Rego and Oscar Monteiro de Marros, vice presidents and Dr. Paulo Tibiriçá general secretary.—Dr. Alberto Inclán Costa was named president of the Sociedad Cubana de Ortopedia y Traumatología recently. Dr. Rafael Peñalver vice president and Dr. Luis Iglesias de la Torre secretary; all are from Havana.

Physician Candidate for President.—Dr. Ramon Grau San Martin, who served as president of Cuba for a time in 1933, again is a candidate for the position.

Deaths in Other Countries

Dr. Johan Harald Ernberg, private physician to King Gustaf of Sweden, died in Stockholm, May 26.—**Dr. Carlos Eduardo Finlay Shine,** formerly secretary of health and professor of medicine at the University of Havana, Cuba, died March 11, aged 76. Dr. Finlay was the son of Carlos J. Finlay, pioneer in yellow fever research. He graduated at Columbia University College of Physicians and Surgeons in 1889. Dr. Finlay had been professor of ophthalmology at the University of Havana since 1907 and had served as dean of the medical school for a year in 1934.

Foreign Letters

LONDON

July 1, 1944.

Criticisms of the National Health Service Scheme

In a letter to the *Times* the president of the Royal College of Surgeons, Sir Alfred Webb-Johnson, points out that a grave defect in the government scheme for a national health service is that the medical profession is not given any direct responsibility for its planning and administration. The physicians are relegated instead to an advisory status, and their advice is not to be made available to the public. They can be of greater service as collaborators than as critics, the letter states. Moreover, their advisory functions at the center are robbed of much of their value by the fact that the medical advisers are to be chosen by the minister of health and not by the profession, although several members of the present advisory committee are ex officio members and so speak in a representative capacity. At the periphery again their function is advisory, but much more efficient planning and administration will be achieved if the profession and voluntary hospitals are made responsible partners in these tasks.

It is also in the people's interest that the freedom of the profession be maintained. Independent practice is a large factor in ensuring this freedom, for it leaves a considerable number of practitioners at liberty to state their views freely and publicly without regard to departmental approval. The continuance of independent medical practice can be ensured by not including in the service those above a certain limit of taxable income who are able and anxious to pay for services as required, it is suggested. Another important way of maintaining the freedom of the profession is avoidance of whole time salaried appointments where they are unnecessary. Contributors should still have the doctor of their choice. The hospital service is a different matter; being an organization of specialist services, it is more suitably provided out of rates and taxes.

There is a proposal to vest in a Central Medical Board—a body of civil service structure appointed by the Ministry of Health—the power to prevent a practitioner from offering his services to public patients in any district of his choice. It is not proposed that he should be prevented from practicing there but only that he should not be allowed public patients. Thus these people would be refused free choice of doctor. It is also proposed to require newly qualified doctors to accept whole time public service for a term of years in order to secure an adequate number for unattractive areas. This is a definite encroachment on the freedom of the citizen, it is maintained.

Rectal Pain

In *Guy's Hospital Reports* Prof. J. A. Ryle has made an important clinical contribution on the subject of rectal pain. He emphasizes the fact that, as Hilton pointed out, pain is often absent altogether in carcinoma of the rectum. This has led repeatedly to delayed and faulty diagnosis. In a series of 28 cases Ryle found pain absent in 8; in another 10 there was abdominal pain (colonic pain above the level of the growth) but no rectal pain, while in the remaining 10 there was pain or discomfort referred to the rectum itself. Thus true rectal pain was found in a little over a third of the cases. A sense of pressure or ineffectual calls to stool may be described, but frequently, urgency, looseness and blood in the stools are more constant and valuable signs than pain. Bladder irritation and referred pains in the testicles, the hip or down the back of the legs are secondary effects, indicating extensions of the growth

and therefore late symptoms. Of the local rectal sensations "a sort of toothache in the rectum," "occasional sharp, shooting pains" and "an obstructed feeling, not pain" were descriptions given by 3 patients. The most severe pain is encountered in cases in which the growth invades the anal canal; in these circumstances there is pain on defecation.

The other more important causes of rectal pain are ball valve accumulation of hard feces, *tabes dorsalis* and nervous proctalgia. In ball valve accumulation the subjects are usually elderly or bedridden, and a recent history of gastric hemorrhage, other dehydration or a barium meal examination is common. Blood or barium sulfate give the requisite firmness and stickiness to the impacted mass to prevent ready evacuation. In hospital cases the cause of the symptoms escaped the recognition of house officers and ward sisters. The pain is likened to labor pains and is described as a "bearing down" pain, which may occur rhythmically. The diagnosis is made by digital examination. In nervous proctalgia there is rectal spasm. The pain starts as a dull ache but rises rapidly to an agonizing form. It is commonly nocturnal and awakens the victim at about 2 a. m. It is frequently associated with fatigue or anxiety and may be associated with sexual excitation. Relief has been obtained by rapid inflation of the bowel with air or by the injection of water. A hot bottle applied to the sacrum may also give relief.

Rapid Treatment of Wounded

The speed with which the war wounded receive medical aid has been described in previous letters and is further illustrated in the Normandy campaign. Surgeons went in with the first waves—with the parachutists and glider troops and in the assault boats. Men were given skilled attention within a few minutes of being hit. Specialized teams carried penicillin, whole blood and plasma into the front lines. During the first few days the wounded in the inland fighting were brought to the beaches in jeeps and later in motor ambulances, placed in "ducks" and run into tank landing craft, which brought them to England. As soon as the vessels bringing tanks from England were unloaded on the beaches they were prepared to receive the wounded, and an emergency operation theater was rigged up. From the moment a man was picked up in the field he was watched over by doctors, surgeons and transfusion experts. Yellow tabs were tied to the wounded taking penicillin, so that further doses could be given as they passed along the evacuation service; red tabs were tied on men taking sulfonamides. During the first day or two 400 bottles of blood were sent across the English channel daily by motor launch, but as the number of casualties was smaller than was expected this supply was cut down. Blood banks were established behind the beaches.

Psychologic Clinic Established at Guy's Hospital

The opening of the York Clinic for Psychological Medicine at Guy's Hospital is a new departure. It is the first clinic of its type in this country specially built at a general hospital as part of a great teaching school. Over twenty years ago the Middlesex Hospital made a pioneer move when, by arrangement with St. Luke's Hospital for Mental Diseases, a small unit was formed at the main teaching hospital for psychologic patients. The Guy's Clinic has been designed in accordance with the best modern experience and has beds for 43 patients. An advantage of the conjunction of a large general hospital with a special unit for mental diseases is that it will encourage sufferers to overcome their usual reluctance to submit themselves to treatment. Moreover, the education of medical students has suffered from the absence of a psychologic department specially built apart from the ordinary hospital. A donation of \$215,000 from the York Trust in conjunction with a gift of half the site by Lord Nuffield has made this project possible.

Treatment of Osteoarthritis by Parathyroidectomy

The late results of the treatment of osteoarthritis by thyroidectomy were studied by Dr. Sebastião Hermeto Junior of the Faculty of Medicine of the University of São Paulo. He emphasized the necessity of correct diagnosis based on an accurate clinical examination of the patient and on careful analysis of roentgenograms and laboratory findings. Dr. Hermeto Junior reported 20 cases with varying forms of osteoarthritis, including some cases of spondylosis. The operation performed in these cases was unilateral parathyroidectomy; 6 patients were operated on a second time in order to reach another gland. The late results are no improvement in 6 cases, improvement in the pain and of the joint block in 10 cases and good results in 4 cases. One of the latter presented before surgical treatment a pathologic condition of one of the severest anatomic forms that the author had ever seen. Dr. Hermeto Junior thinks that parathyroidectomy has favorable indications for treating osteoarthritis.

Narrowing of the Esophagus Caused by Lye

Dr. J. A. Arruda Botelho, endoscopist of the Beneficência Portuguesa de São Paulo, has described a new technic by which he has obtained good results in all cases of narrowed esophagus due to lye which he has treated. There were 15 patients. The process consists in using the dilator of Plummer-Jackson after the patient has submitted to a previous gastrostomy. The gastrostomy permits a conducting thread to extend from the mouth to the gastrostomy, permitting the dilator to slide by the thread, dilating the esophagus its full length. The conducting thread, well stretched, permits a forced dilatation without any danger whatever to the patient, because the point of the dilator adapts itself to all the irregularities of the esophagus.

After the dilation is completed, in about three months the author begins to use the esophagoscope of Chevalier Jackson to maintain the dilatation until the esophagus is completely healed.

The only difficulty with this procedure consists in passing the thread from the mouth to the gastrostomy, and it is just this which makes the method original and guarantees its efficiency and harmlessness.

When the narrowing is not fully closed, the patient can be made to swallow a fine linen thread, and by simple suction this passes through the gastrostomy. Joined to this fine thread is a thicker one which is necessary for the dilation. If the thread will not pass by swallowing, the esophagoscope of Chevalier Jackson must be used.

Brief Items

Dr. Estellita Lins, a practicing surgeon of Rio de Janeiro and a graduate from the emergency course in military medicine, has been called to active service in the army. Dr. Estellita Lins has a good background in war surgery, as he served during the first world war in France at the Paris Hospital Vaugirard.

An association of physicians working in hospitals, sanatoriums and allied institutions has recently been organized. The governing board of the association includes Dr. Edgard de Almeida, Dr. João Borges Filho and Dr. E. Carlos Carvalho.

A School of Hygiene and Public Health has been created at the University of São Paulo as a development of the course in hygiene and public health run by the Institute of Hygiene of the university. The late malariologist Dr. Samuel T. Darling and Dr. W. G. Smillie, professor of public health at Cornell Medical College, both taught in São Paulo during the early years of the course in hygiene and public health. Dr. Geraldo

Paula Souza, professor of hygiene at the University of São Paulo, now commissioned in Washington, has been a leading professor of the course and is expected to be the dean of the new school.

The National Academy of Medicine of Rio de Janeiro has recently created a medal prize under the name of Dr. Rocha Vaz, to be awarded every year to the best paper from a Brazilian author concerning human constitution, endocrinology and metabolism.

Dr. Christopherson and the Special Service of Public Health

Dr. E. H. Christopherson, superintendent of the Brazilian Special Service of Public Health, arrived in Rio de Janeiro recently, back from a trip to the United States, where he presented a detailed report of his work to Gen. George C. Dunham, director of the Division of Health of the Office of the Coordinator of Inter-American Affairs. As reported in a previous letter (*THE JOURNAL*, Sept. 11, 1943) the Special Service of Public Health is an organization created cooperatively by the American and Brazilian governments to take charge of health work in the Amazon basin, where a large number of workers, forming the so-called rubber army, are now subjected to the hazards of many tropical diseases. Dr. Christopherson stopped at Belém, state of Pará, at the mouth of the Amazon River, where he inspected the services located in the neighborhood of that city. Speaking to newsmen on his arrival in Rio de Janeiro, Dr. Christopherson pointed out that perfect cooperation between the American and Brazilian authorities spoke well for the success of the enterprise. He stressed the need for continuing this important health work after the war.

Vaginal Hysterectomy as a Prophylactic Measure In and After the Menopause

From 1932 until 1941, 1,692 women died from cancer of the uterus and 639 from breast cancer in Rio de Janeiro. Thirty cases of vaginal hysterectomy performed in women in the menopause or postmenopause, most of whom were referred for uterine bleeding in nonmalignant states, are reported by Prof. Arnaldo de Moraes. Supporting this indication for surgical treatment, different lesions localized in the uterus (proliferative, erosions of the cervix, chronic cervicitis, chronic endometritis, hyperplasia of the endometrium, myomas and uterine atrophy) were found. The role those lesions may display in the incidence of cancer, in connection with personal or hereditary, physiologic and pathologic factors, is emphasized.

From his study the author concludes that vaginal hysterectomy, performed under local anesthesia, as routinely practiced in his clinic, is indicated when those associated factors are present and when the uterus is already functionless and on account of its lesions must be considered as potentially malignant.

Marriages

GEORGE ANDERSON FOWLER, New York, to Miss Diana A. Skouras at Mamaroneck, N. Y., June 28.

JULIUS E. MONEAGLE, Madison, N. J., to Miss Dorothy Phyllis Costabile of New York recently.

ALVIN FRANCIS ST. AMANT, Gonzales, La., to Miss Nancy Webb of Demopolis, Ala., July 8.

PAUL I. KEARNEY, Brooklyn, to DR. GRACE C. VANDERPOEL of Rutherford, N. J., July 1.

JOHN A. WRIGHT JR. to Miss Mary Catherine Campbell, both of Doswell, Va., June 3.

VICTOR G. BALEONI, Boston, to Miss Marjorie Fletcher in New York, June 17.

CHARLES SHORNSTEIN to Miss Estelle Hartman, both of New York, July 2.

Deaths

William Alexander Lambeth, Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1892; served as instructor in physical culture, director of the Fayerweather Gymnasium, lecturer on hygiene and materia medica, adjunct professor and professor of hygiene and materia medica and professor of hygiene at his alma mater; also superintendent of buildings and grounds from 1905 to 1928; secretary of the general athletic association of the University of Virginia from 1897 to 1921; vice president of the department of physical education at the Chicago Exposition in 1893; member of the American College Directors Association and in 1896 vice president; member and from 1897 to 1899 president of the Virginia Intercollegiate Athletic Association; served as treasurer of the National Collegiate Athletic Association; member of the American Olympic Committee for the Stockholm games in 1912; member of the track rules committee of the National Collegiate Athletic Association and a member of the football rules committee from 1908 to 1921; past president of the Society of Directors of Physical Education; chairman of the athletic conference of Southern state universities; member of the American Seismological Society, Raven Society and the American Society of the Royal Italian Orders; decorated a Cavalier in the Order of the Crown of Italy in 1930 and Commendatore in 1933; honorary member of the American Institute of Architects; the Lambeth athletic field at the University of Virginia is named for him; author of "Trees and How to Know Them," "Thomas Jefferson's Architecture," "Geology of the Monticello Area," "School of Athens" and "Food and Dietetics"; died June 24, aged 76, of heart disease.

Abell Duncan Hardin, Dallas, Texas; Baylor University College of Medicine, Dallas, 1909; member of the State Medical Association of Texas, Dallas Southern Clinical Society and the Texas Ophthalmological and Otolaryngological Society; president of the Dallas Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; assistant professor of clinical otolaryngology and bronchoscopy at the Southwestern Medical College of the Southwestern Medical Foundation since 1943; associate in clinical ophthalmology and otolaryngology at his alma mater 1917-1920, assistant 1920-1924, instructor 1924-1931, instructor in clinical otolaryngology and bronchoscopy 1931-1938 and assistant professor 1938-1943; served as dispensary otolaryngologist and bronchoscopist, Baylor Hospital; died May 10, aged 64.

Isaac Hamilton Browne, Winchester, Ky.; Kentucky School of Medicine, Louisville, 1897; member of the Kentucky State Medical Association; served for eighteen months at Base Hospital number 120 at Tours, France, during World War I and discharged with the rank of captain; served as examiner for the local Selective Service Board during World War II; for many years health officer of the city of Winchester and Clark County; on the staff of the Clark County Hospital; served as surgeon for the Louisville and Nashville and the Chesapeake and Ohio Railroad companies; a charter member of the Rotary Club; died in the Veterans Administration Facility, Lexington, June 19, aged 67, of gangrene of the lower extremities and general arteriosclerosis.

Adolph Hartung @ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; professor of radiology at his alma mater, now known as the University of Illinois College of Medicine; specialist certified by the American Board of Radiology, Inc.; member of the American Roentgen Ray Society, Radiological Society of North America, Inc., and the American College of Radiology; formerly on the staffs of the Alexian Brothers', Cook County, Policlinic and Henrotin hospitals; consultant, Women and Children's Hospital; on the staff of the Research and Educational Hospitals, University of Illinois, where he died May 29, aged 61, of coronary stenosis.

Louis Curtis Ager, Warner, N. H.; Long Island College Hospital, Brooklyn, 1893; member of the New Hampshire Medical Society; at one time instructor in pediatrics at his alma mater; past president of the Brooklyn Pediatric Society; formerly served with the city health department of Brooklyn; formerly on the staffs of the Potts Memorial Institute, Livingston, N. Y., Veterans Administration Facility, Rutland Heights, Mass., Long Island College Hospital, Kingston Avenue, Norwegian and St. Mary's hospitals, Home for Consumptives and the Home for Friendless Women and Children, all of Brooklyn; died May 18, aged 75, of a self-inflicted bullet wound.

Theodore F. Heavenrich @ Port Huron, Mich.; Detroit College of Medicine, 1900; past president of St. Clair County Medical Society; formerly councilor of the Seventh District of the Michigan State Medical Society; served as surgeon for the Rapid Railway System and Detroit United Railway and as assistant surgeon for the Pere Marquette Railway; formerly medical examiner for various insurance companies; physician and surgeon for the Port Huron Sulphite and Paper Company and the Detroit Edison Company; on the staff and formerly medical director of the Port Huron Hospital, where he died May 5, aged 69, of heart disease.

Charles Benjamin Yost @ Bloomsburg, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1910; served as president and secretary of the Columbia County Medical Society; secretary of the Bloomsburg Board of Health; during World War I a medical examiner of the exemption board in District number 1, and served in the medical corps of the U. S. Army; member of the Selective Service System during World War II; a charter member of the Kiwanis Club; medical director of Columbia County Red Cross; on the staff of the Bloomsburg Hospital, where he died June 28, aged 56, of cerebral hemorrhage.

Lawrence Chamberlain Grosh @ Toledo, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896; specialist certified by the American Board of Internal Medicine; served as a captain in the medical corps of the U. S. Army during World War I; instrumental in building the Toledo Hospital in 1931, serving as chief of staff for twelve years; active in the completion of the Toledo Hospital Institute for Medical Research in 1942; died July 6, aged 73, of hemorrhage from the internal mammary artery caused by a fracture of the sternum, which was due to osteoporosis.

Rush Leslie Burns, Los Angeles; Rush Medical College, Chicago, 1906; fellow of the American College of Surgeons; for many years city and county health officer in Two Harbors, Minn., where he had been one of the physicians in charge of the Burns and Christensen Hospital and served as chief surgeon for the Duluth and Iron Range Railroad and assistant chief surgeon, Duluth, Missabe and Northern Railroad Company; formerly part owner and physician in charge of the Soudan Hospital, Soudan; died in Santa Monica Hospital, Santa Monica, May 9, aged 66, of cirrhosis of the liver.

Richard Edward Albert, Portsmouth, Va.; University of Virginia Department of Medicine, Charlottesville, 1919; member of the Medical Society of Virginia; on the staffs of the Parrish Memorial Hospital and the King's Daughters' Hospital, where he died May 30, aged 48, of left hemiplegia, arteriosclerosis and malignant hypertension.

Charles K. Albertson, Benton, Pa.; Maryland Medical College, Baltimore, 1907; member of the Medical Society of the State of Pennsylvania; past president of the Columbia County Medical Society; on the staff of the Bloomsburg Hospital, Bloomsburg, where he died May 8, aged 60, of peritonitis and perforated appendicitis.

Irving Sydney Barcham @ New York; New York University Medical College, New York, 1935; diplomate of the National Board of Medical Examiners; assistant adjunct surgeon, Hospital for Joint Diseases, where he died May 28, aged 34, of essential hypertension and cerebral hemorrhage.

Samuel Graham Bay, Santa Monica, Calif.; Ohio Medical University, Columbus, 1898; member of the California Medical Association; formerly passed assistant surgeon, U. S. Public Health Service reserve; served during World War I; on the staff of the Veterans Administration Facility, West Los Angeles, where he died May 18, aged 67, of heart disease and arteriosclerosis.

James S. Bingham, Middlesboro, Ky.; University of Louisville (Ky.) Medical Department, 1885; served three terms as county judge and one term as county court clerk; died in the Pineville Community Hospital, Pineville, May 29, aged 82.

William Purnell Bond, Ruston, La.; Memphis (Tenn.) Hospital Medical College, 1901; member of the Louisiana State Medical Association; died in the Ruston-Lincoln Sanitarium May 5, aged 74, of cerebral embolism.

Stanley James Bown, Richwood, Ohio; Starling Medical College, Columbus, 1898; served as secretary and treasurer of the Union County Medical Society; died May 16, aged 71, of cerebral hemorrhage.

Charles Henry Brush, Kings Park, N. Y.; Fordham University School of Medicine, New York, 1913; first lieutenant

in the medical corps of the U. S. Army during World War I; assistant director, Kings Park State Hospital; died May 29, aged 55, of coronary occlusion.

Edward David Burns, Arlington, Mass.; Tufts College Medical School, Boston, 1936; served an internship at the Carney Hospital, South Boston, and St. John's Hospital, Lowell, and a residency in the Sanatorium Division of the Boston City Hospital; commissioned a first lieutenant in the medical corps reserve on June 15, 1936 and reappointed a captain, Army of the United States, on June 17, 1942; released from service Feb. 25, 1943; died in the Baker Memorial Hospital, Boston, June 19, aged 34.

Oliver Llewellyn Butterick, Toledo, Ohio; University of the City of New York Medical Department, New York, 1887; died May 3, aged 82, of cardiac asthma.

John Joseph Cochran, Natick, Mass.; Harvard Medical School, Boston, 1923; member of the Massachusetts Medical Society; councilor for the Middlesex South District Medical Society; associate examiner, local Selective Service Board number 105; surgeon on the staff of the Leonard Morse Hospital, where he died May 1, aged 47, of bronchopneumonia and bronchial asthma.

Fountain Lee Cook, Independence, Mo.; University Medical College of Kansas City, 1897; member of the Missouri State Medical Association; health officer of Independence; on the staff of the Independence Sanitarium and Hospital; died May 23, aged 80, of acute cardiac dilatation and congestive heart failure.

Fred Sutton Cook, Eau Claire, Wis.; State University of Iowa College of Medicine, Iowa City, 1907; member of the State Medical Society of Wisconsin, died July 4, aged 62, of myelogenous leukemia.

William Bryant Cutts, Providence, R. I.; University of Pennsylvania Department of Medicine, Philadelphia, 1899; member of the Rhode Island Medical Society; fellow of the American College of Surgeons; past president of the Providence Medical Society; during World War I served as a surgeon at the U. S. Army General Hospital at Fort McHenry, Md., with the rank of captain; associate surgeon, Homeopathic Hospital; for many years on the staff of the Rhode Island Hospital, where he died May 24, aged 75.

Homer Jury Davis @ Newark, Ohio; Rush Medical College, Chicago, 1904; fellow of the American College of Surgeons; past president of the Licking County Medical Society; member of the board of directors and second vice president of the Ohio Society for Crippled Children; physician for the Licking County Children's Home; chief of staff, Newark City Hospital; surgeon, Pennsylvania and Baltimore and Ohio railroads; died in the Mount Carmel Hospital, Columbus, May 6, aged 67, of perforated duodenal ulcer and peritonitis.

John Woodfin Davis @ Tullahoma, Tenn.; University of Tennessee College of Medicine, Memphis, 1935; member of the Medical Association of the State of Alabama; first lieutenant, medical reserve corps, U. S. Army, not on active duty; served as assistant surgeon in the U. S. Public Health Service reserve; died in the University Hospital, Augusta, Ga., May 25, aged 34, of tumor of the spine.

Llewellyn Moore Dykes Sr., Baltimore; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; served during World War I; died in Fort Howard May 18, aged 57, of hematemesis and a blood dyscrasia.

Ray Manier Eaton, Rochester, N. Y.; Albany (N. Y.) Medical College, 1911; member of the Medical Society of the State of New York; served as a medical officer with the British Expeditionary Forces in France during World War I; on the staffs of the Rochester General and Park Avenue hospitals; died May 19, aged 56, of coronary occlusion.

Frederick George Eberhard, Three Rivers, Mich.; Northwestern University Medical School, Chicago, 1912; served an internship at the City and County Hospital, Denver; a captain in the medical corps of the U. S. Army during World War I; author of the "Thirteenth Murder" and other mystery stories; died May 31, aged 55, of cerebral hemorrhage.

Sidney Jacob Eichel, Evansville, Ind.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; member of the Indiana State Medical Association; past president of the Ohio Valley Medical Association; died May 14, aged 67, of myocardial degeneration and cardiac asthma.

Charles M. Eisenbeiss, South Bend, Ind.; Kentucky School of Medicine, Louisville, 1892; at one time postmaster of Elkhart and coroner of Elkhart County; formerly vice

president of the Indiana State Board of Health; died in the Epworth Hospital, May 3, aged 73, of carcinoma of the bladder.

Lorenzo D. Eley, Plymouth, Ind.; College of Physicians and Surgeons, Keokuk, Iowa, 1887; member of the Indiana State Medical Association; formerly health officer and assessor of the county; served as secretary of the county board of health; died May 14, aged 88, of pulmonary edema, chronic myocarditis and pleural effusion.

James Wade Elphinstone, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1901; member of the Medical Society of the State of Pennsylvania; served on the staff of the Allegheny General Hospital; died May 29, aged 66, of coronary occlusion and hypertension.

Charles Engelke @ Waterbury, Conn.; Columbia University College of Physicians and Surgeons, New York, 1902; health officer, 1910-1911; since 1904 on the staff of the Waterbury Hospital, where he died May 22, aged 74, of coronary occlusion.

Harry Howard Flagg, Boston; Tufts College Medical School, Boston, 1908; member of the Massachusetts Medical Society; served in France during World War I; on the staffs of the Chelsea Memorial Hospital, Chelsea, and the Lawrence Memorial Hospital, Medford; died May 25, aged 63, of pernicious anemia and uremia.

George Simeon Fultz @ Butterworth, Va.; Medical College of Virginia, Richmond, 1906; member of the board of health and Selective Service Board; surgeon for the Seaboard Air Line; on the staff of the Petersburg Hospital, Petersburg; died May 16, aged 66, of coronary thrombosis.

Nathaniel Howland Gifford, Providence, R. I.; Harvard Medical School, Boston, 1903; member of the Rhode Island Medical Society; for many years a member of the consulting staff of Butler Hospital and chief of surgical service at Charles V. Chapin Hospital; on the staff of the Rhode Island Hospital; died in the Jane Brown Memorial Hospital May 25, aged 65, of coronary thrombosis.

Carlos A. Gooch, Oak Hill, W. Va.; University of Louisville (Ky.) Medical Department, 1898; died in a local hospital July 14, aged 69, of heart disease.

Lee E. Grant, Detroit; Kentucky School of Medicine, Louisville, 1902; specialist certified by the American Board of Otolaryngology; served on the staff of the Grace Hospital; died May 31, aged 73.

George Orbin Hall, Murrysburg, Pa.; College of Physicians and Surgeons, Baltimore, 1904; died May 10, aged 69, of coronary occlusion.

William Antoine Hall @ St. Louis; Marion-Sims College of Medicine, St. Louis, 1893; formerly professor of physiology at the St. Louis College of Physicians and Surgeons; in 1943 was honored by the St. Louis Medical Society in recognition of his completion of fifty years in the practice of medicine; on the staffs of the Bethesda General Hospital and the Missouri Baptist Hospital, where he died May 28, aged 74, of intestinal obstruction.

Albert Henry Hamel @ St. Louis; St. Louis Medical College, 1890; an Affiliate Fellow of the American Medical Association; past president of the Missouri State Medical Association and St. Louis Medical Society; served as member and as president of the state board of health; a captain in the medical corps of the U. S. Army during World War I; on the staffs of the Missouri Baptist, Missouri Pacific and the Josephine Heitkamp Memorial hospitals; died May 17, aged 77, of coronary thrombosis.

Jabez Peter Hankins, Orange, Va.; Medical College of Virginia, Richmond, 1908; member of the Medical Society of Virginia; served as secretary and president of the Orange County Medical Society; chairman of the Selective Service Board; member of the Orange County Board of Health; died May 7, aged 64, of coronary thrombosis.

James Clinton Hawkins @ Coraopolis, Pa.; Western Reserve University School of Medicine, Cleveland, 1915; served as a captain in the medical corps of the U. S. Army during World War I; on the staff of the Sewickley Valley Hospital, where he died May 24, aged 55, of coronary occlusion.

Moses W. Hoge @ St. Louis; St. Louis Medical College, 1883; an Affiliate Fellow of the American Medical Association; formerly an instructor in neurology and chief of clinic

for nervous diseases at the Washington University School of Medicine; died in Farmington, Mo., May 5, aged 83, of arteriosclerosis.

Greg Hoskins • Long Beach, Calif.; Cooper Medical College, San Francisco, 1910; served during World War I; president of the Harbor Branch of Long Beach Academy of Medicine; on the staff of the Seaside Hospital, where he died May 10, aged 57, of nephritis.

Carl Adolph Huber • Rochester, N. Y.; College of Physicians and Surgeons, New York, 1894; at one time coroner's physician; served as examining physician for local draft board number 551 for three years; consulting surgeon at the Monroe County Infirmary; member of the board of directors and consulting surgeon at the Park Avenue Hospital, where he died May 31, aged 71, of cerebral hemorrhage.

Robert E. Innis, Marion, Ind.; Eclectic Medical Institute, Cincinnati, 1886; also a pharmacist; died in the Marion General Hospital May 9, aged 83, of coronary occlusion.

Theron Skeels Jackson • Cleveland; Western Reserve University School of Medicine, Cleveland, 1913; fellow of the American College of Surgeons; served in France with the Lakeside Unit as a captain in the medical corps during World War I; served on the staffs of the Huron Road Hospital, East Cleveland, and the Woman's and St. Vincent Charity hospitals; died May 31, aged 58, of coronary disease.

Edward Lyon Sr., Williamsport, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; past president of the Lycoming County Medical Society; veteran of the Spanish-American War; a medical examiner on the draft board during World War I; served as a school director and a member of the city council; on the staff of the Williamsport Hospital; died in the Veterans Administration Facility, Coatesville, May 4, aged 69.

Alberta Helen Murwin Miners, St. Joseph, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1903; died May 6, aged 74, of chronic nephritis.

Arvel R. Ponton • Fort Worth, Texas; University Medical College of Kansas City, Mo., 1906; formerly one of the operators of the Ponton-Brown Hospital, Edinburg, now known as the Grandview Hospital; head of Ponton Clinic; died in the Methodist Hospital April 11, aged 59, of injuries received when his horse fell and rolled over him.

Walter McClellan Smalley, Dayton, Ohio; Fort Wayne College of Medicine, Fort Wayne, Ind., 1889; at one time medical supervisor for the Miami conservancy district; died May 1, aged 82, of heart disease.

Theodore Sureth, Scranton, Pa.; New York Homeopathic Medical College and Hospital, New York, 1893; member of the Medical Society of the State of Pennsylvania; one of the founders and president of the staff of the Hahnemann Hospital; a director of the North Scranton National Bank; died May 6, aged 83, of cerebral hemorrhage due to cardiovascular disease.

Harry Lee Upshaw, Social Circle, Ga.; Emory University School of Medicine, Atlanta, 1915; member of the Medical Association of Georgia; served in France during World War I; for many years local surgeon for the Georgia Railroad; died April 6, aged 50, of cirrhosis of the liver.

Edward Joseph Van Metre, Tipton, Iowa; Rush Medical College, Chicago, 1886; served on the staffs of St. Luke's Methodist Hospital, Cedar Rapids, and University Hospital, Iowa City; surgeon for the Rock Island Railroad; died June 16, aged 83, of hypertensive heart disease and general arteriosclerosis.

De Ver Oram Williams, Durhamville, N. Y.; University of the City of New York Medical Department, New York, 1885; died July 6, aged 81.

John Mill Wright • Grand Rapids, Mich.; Detroit College of Medicine, 1895; at one time instructor at the Grand Rapids Medical College; formerly secretary of the Kent County Medical Society; served as county coroner and as a member of the board of education; chief of staff, Evangeline Home; staff visiting physician, St. Mary's Hospital, where he died April 27, aged 69, of coronary thrombosis.

Oscar Olie Young, Baldwin Park, Calif.; Kansas City (Mo.) Medical College, 1896; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; died in the Veterans Administration Facility, West Los Angeles, April 9, aged 75, of retroperitoneal fibrosarcoma with generalized metastases and bronchopneumonia.

DIED WHILE IN MILITARY SERVICE

Martin Batts Jr., Grand Rapids, Mich.; University of Michigan Medical School, Ann Arbor, 1933; member of the Michigan State Medical Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; served an internship and later residency in surgery and orthopedics at the University of Michigan Hospital, Ann Arbor; formerly fellow in surgery at the Mayo Foundation, Rochester, Minn.; served on the consulting staff of St. Mary's Hospital and on the staffs of the Butterworth and Blodgett Memorial hospitals; commissioned a captain in the medical corps of the Army of the United States on July 30, 1942; later promoted to major; died in the Percy Jones General Hospital, Battle Creek, July 8, aged 36, of acute myelogenous leukemia.

Merrick Roblee Breck • Chicago; Rush Medical College, Chicago, 1924; served an internship at the Kings County Hospital, Brooklyn; on the attending staff of the Ravenswood Hospital; formerly on the staff of the Atchison, Topeka and Santa Fe Railroad Hospital, La Junta, Colo.; commissioned a first lieutenant in the medical reserve corps of the U. S. Army on Dec. 3, 1931; subsequently promoted to captain, major and lieutenant colonel; drowned in New Guinea June 9, aged 44.

William Elijah Moore Devers • Colonel, M. C., U. S. Army, Cowles, Neb.; University of Illinois College of Medicine, Chicago, 1914; U. S. Army Medical School, 1921; hospital apprentice, first class, in the U. S. Navy from May 12, 1905 to May 24, 1909; second lieutenant, Fourth Infantry, South Dakota National Guard in 1909; first lieutenant and battalion adjutant from August 1911 to June 1914; served during World War I; entered the medical corps of the U. S. Army as a captain in 1920, promoted to major in 1929, a lieutenant colonel in 1937 and later a colonel; died in the Army and Navy General Hospital, Hot Springs National Park, Ark., March 30, aged 59, of carcinoma of the stomach.

William Francis Drew, San Francisco; Stanford University School of Medicine, San Francisco, 1941; served an internship at the San Francisco Hospital; fellow in internal medicine at the Cleveland Clinic Foundation Hospital, Cleveland; commissioned a first lieutenant in the medical corps, Army of the United States, March 10, 1942; died in the North African area May 23, aged 29, of fractured skull received in a fall.

Chapman Q. Dykes, Haines City, Fla.; Emory University School of Medicine, Atlanta, Ga., 1916; member of the Florida Medical Association; past president of the Franklin-Gulf Counties Medical Society; formerly associated with the U. S. Public Health Service; commissioned a captain in the medical corps, Army of the United States, on Aug. 20, 1942 and began active duty on Sept. 4, 1942; later promoted to major; died in Camp Davis, N. C., May 3, aged 51, of cerebral hemorrhage, pulmonary edema and heart disease.

Lewis Jennings Geerlings, Fremont, Mich.; Rush Medical College, Chicago, 1933; completed an internship at the Presbyterian Hospital, Chicago; member of the Michigan State Medical Society; served as president of the Newaygo County Medical Society; began active duty as a first lieutenant in the medical corps, Army of the United States, on May 16, 1942; later promoted to captain; a flight surgeon in the air corps; killed in an airplane crash while on a routine flight from one air base to another at Corsica, May 10, aged 36.

Charles David Horn, Baltimore; Harvard Medical School, Boston, 1941; served an internship and residency at the Sinai Hospital; commissioned a first lieutenant in the medical corps, Army of the United States, on Sept. 24, 1942; died Aug. 11, 1943, aged 26, of a broken neck received in a motor vehicle accident.

Jack Kinell, Houston, Texas; University of Kansas School of Medicine, Kansas City, 1936; member of the State Medical Association of Texas; served an internship in the City Hospital, Cleveland, and a fellowship in internal medicine at the Cleveland Clinic Foundation Hospital; commissioned a lieutenant (jg) U. S. Naval Reserve on March 21, 1942 and began active duty on April 19, 1942; promoted to lieutenant March 1, 1943; served for twenty months in the South Pacific; died in the Naval Air-Station at Corpus Christi April 15, aged 31.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Bio-Mineral—Michel Manteris and George Aristotle, who put out this product under the firm name Bio-Mineral Products Company, Detroit, stipulated with the Federal Trade Commission in August 1943 that they would discontinue the following advertising misrepresentations. That this product is an adequate or dependable remedy, treatment or relief for a number of ailments including tuberculosis, cancer, heart disease, goiter, infantile paralysis, arthritis and sciatica; that Bio-Mineral contains an effective amount of any mineral recognized by medical science as a preventive of, or treatment for, any of the disorders that the promoters mention, or that the preparation is drugless and that its use will assure health, that it will aid in restoring a ruined weak or sick body, or be of benefit in anemic conditions, except such as result from uncomplicated iron deficiency, that it will have a general tonic effect on the body or be a body builder, that it is rich in minerals or contains a significant amount of any mineral other than iron.

Blis-To-Sol—This is a product of the Central Pharmacy, Inc., trading as Blis-To-Sol Company, Fitzgerald, Ga. In June 1943 the concern entered into a stipulation with the Federal Trade Commission, agreeing to cease representing that the preparation is a cure or remedy for eczema, poison oak or poison ivy, or that it has any value in the treatment thereof, in excess of affording relief from the symptoms of itching.

"Complete Guide for the Deafened"—In June 1943 one Benjamin H. Levine, trading as Harvest House, New York, which distributes this book, entered into a stipulation with the Federal Trade Commission in which he agreed to cease representing that the work contains directions of such nature that merely by following them the sense of hearing will be improved, saved or restored, or that it contains directions of such nature that they can be followed without assistance or direction by a person in the treatment of defective voice or speech. Levine further agreed not to publish or cause to be published any advertisement for the book which might fail to reveal that the volume refers the reader to other sources of information and guidance, as well as to mechanical aids for many of the improvements and for advice as to procedures to be followed in the treatment of deafness.

Grobowski Nostrums—These are put out by Albert G. Grobowski and Company, Plymouth, Pa., which concern in July 1943 stipulated with the Federal Trade Commission to discontinue any advertisement which failed to reveal that the use of "Grobowski's Headache Powders" may cause collapse, that repeated doses may cause dependence on the drug, that not more than two powders should be taken within 24 hours, and that the preparation should not be given to children, that repeated use of "Grobowski's Nasal Jelly" by aged or debilitated persons or by infants may produce oil injury in the lungs, and that this nostrum should not be used by persons having heart disease or high blood pressure, that "Grobowski's Jadol" is a laxative and should not be taken in the presence of nausea, vomiting, abdominal pains or other symptoms of appendicitis, that frequent use of either "Nervotene" or "Grobowski's Preparation 'C'" may result in mental derangement or cause skin eruption, that "Grobowski's Powders for Round Worms" contain a laxative and should not be taken when symptoms of appendicitis are present, or used in excess of the recommended dosage, that castor oil or foods or other preparations containing oil or fat should not be used while such powders are being taken, and that the prescribed dose should not be used if there is discharge from the ear or if the ear drum is punctured or perforated, and that "Grobowski's Reviva Powders" and "Eguterro" are laxatives and should not be taken when symptoms of appendicitis are observed. The stipulation provided, however, that the statement, "Caution: Use only as directed" would be a sufficient warning in the advertising if the label contained adequate and specific warning as to the potential danger to health.

Hudson Specialties Company's Sun Lamps—The Hudson concern's name is a trade style used by one Hugo Gernsback at New York, who, in addition to being a publisher, engages in the sale of various electrical and mechanical devices. His lamps, of the carbon arc variety, were supplied to him by manufacturers in Philadelphia and New York. In July 1943 Gernsback stipulated with the Federal Trade Commission to discontinue the following advertising misrepresentations. That the rays produced by his ultraviolet lamp will improve glandular action, give the body nutrition or keep one healthy, that the device should properly be designated "sun lamp", that the use of infra-red lamps will be an effective means of toning up the system and helping to throw off certain body ailments, or that their use will help nature in its curative powers by forming

heat units in the blood, or be of any therapeutic value except as means to supply heat, and then only when heat is not contraindicated. Gernsback further agreed to discontinue any advertising representations which failed to reveal that use of the device in certain contraindicated conditions may result in serious injury to health, and that there is potential danger in the improper use of these. It was provided, however, that if appropriate warnings to this effect are given on the label, the advertising need contain only the statement "Caution: Use only as directed."

Polanka and Zielanka—These preparations are put out by Bol-Jaw Rosalak and Zenobia Rosalak, trading as Belvedere Products, New York. In July 1943 they stipulated with the Federal Trade Commission that they would discontinue the following advertising misrepresentations. That Polanka will aid the digestive system, regulate the stomach, provide relief for digestive disturbances generally, or have any value other than that of temporarily relieving constipation, that Zielanka will relieve rheumatic, arthritic or muscular pains, be an adequate treatment or effective remedy for such conditions, or offer any value other than that of temporarily relieving constipation. Further, they agreed to discontinue any advertisement which represented that use of either of the preparations is safe, or which failed to reveal the potential danger in their use in the presence of abdominal pains, nausea or other symptoms of appendicitis, provided, however, that if the directions for use given on the label contain an adequate warning of their potential danger, such advertisement need contain only the statement "Caution: Use only as directed."

R-Q—In July 1943 the Federal Trade Commission accepted a stipulation from R. Q. Howe, trading as R. Q. Laboratories, Alhambra, Calif. In this he agreed to discontinue the following advertising misrepresentations. That R. Q. is a remedy or cure for eczema, poison oak or poison ivy, or a treatment for such conditions aside from affording relief from itching, that it is a treatment for skin infections, without specifying the conditions for which it supposedly has therapeutic value, and that it is a remedy or cure for ringworm, unless it is explained that the product will not destroy deep seated ringworm infections. Howe further agreed to cease representing, through use of the word "Laboratories" in his trade name, that he maintains or operates a laboratory, and to discontinue any advertisements which failed to reveal that his nostrum may produce skin irritations and that its use should be discontinued as soon as irritation appears. This warning, however, the stipulation permitted him to omit from his advertisements, provided they included the statement, "Caution: Use only as directed" when the same warning appeared on the labels.

Superior Bath Cabinet—In July 1943 the Cabinet Manufacturing Company, Quincy, Ill., and the Mace Advertising Agency, Inc., Peoria, Ill., stipulated with the Federal Trade Commission that they would cease representing that this cabinet is safe, economical or effective in reducing weight, that it will help to build or maintain resistance against disease, that the use of it tones the skin, restores a rosy flush to sallow skin, purges the pores, stimulates the sebaceous glands and removes impurities from the sweat glands, that it supplies the tissues with new blood and removes toxic substances from the blood stream, that it relieves lumbago, neuralgia, rheumatism and muscle soreness and headaches, breaks up or helps to forestall colds, la grippe and influenza, aids impaired kidney functions, brings relaxation or helps prevent insomnia or nervousness. The respondents further agreed to discontinue any advertisements which failed to reveal that there is danger of accidental burn in using the device as directed, that care should be exercised to prevent injury and someone should be in attendance while the cabinet is being used to provide a steam heat bath, a dry heat sweat bath, or as a source of infra-red heat, and that exposure to the heat rays may result in a skin burn. The stipulation provided, however, that the statement, "Caution: Use only as directed" would be a sufficient warning in the advertisements if the directions accompanying the cabinet contain a statement to the same effect.

Supertan Ultra-Violet Ray Sun Lamps—The Ultra Violet Ray Laboratories, Inc., New York, represented in their advertising that these devices were genuine sun lamps and that the radiation that they produced was "the same as in natural sunlight", that a report on carbon arc lamps by the United States Bureau of Standards confirmed the corporation's claim that its lamps "produce the closest duplication of natural sunshine of any known artificial source of energy," and that the lamps, by means of their radiation, would be beneficial to "rashy, pimply skins," certain forms of anemia, deficiency diseases due to lack of vitamins except vitamin D, tuberculosis of the bones, joints and glands, sinus infections, ulcers, wounds, sore throat, tonsillitis, neuritis and certain skin disorders. In a stipulation that the concern signed with the Federal Trade Commission in June 1943, it agreed to discontinue these misrepresentations and to cease disseminating any advertisement that failed to reveal that excessive exposure to the lamp might result in severe sunburn, and that the device should not be used in cases of pellagra, lupus erythematosus, certain types of eczema, burns and sunburn, and should never be employed unless goggles are worn to protect the eyes. It was provided, however, that if the directions for use of the lamps appear on the label and carry an adequate warning of their potential danger to health, such advertisement need simply warn "Caution: Use only as directed."

Vita Brush—This is an electrically driven device for use on the hair and scalp, and is put out by the Hershey Manufacturing Company of Chicago, whose advertising is handled by George J. Kirkgasser and Leslie A. Drew, trading as Kirkgasser Drew. In June 1943 both concerns stipulated with the Federal Trade Commission that they would cease representing that the device will check or prevent falling hair or baldness, restore life to dead hair or prevent or ward off dandruff, that it is the secret of healthy hair, is the answer to hair worries or effective for headaches of a circulatory origin, that it has any effect in the treatment or prevention of head colds or congestion, will relieve nervous insomnia, insure a good night's sleep, or cause the hair to grow thicker.

BENIGN AND MALIGNANT TUMORS OF THE FOOT

MACROCYTIC ANEMIA OF PREGNANCY

To the Editor:—The rare macrocytic anemia of pregnancy is a serious and incompletely understood disease. Some writers have considered it a form of pernicious anemia, but most observers have been impressed particularly by its resemblance to the hemolytic anemias. My purpose in this communication is to report some recent observations of mine which suggest a plausible explanation for the pathogenesis of this disease.

Long ago Ottenberg and Thalheimer (*J. M. Research* 33:213, 1915) in transfusion experiments on cats observed that, while the first transfusions were well tolerated, when the transfusions were repeated the recipients eventually developed acute hemolytic reactions followed by a severe erythroblastic anemia. Similarly, in human Rh negative patients who have become sensitized to the Rh factor it has been observed that transfusions of Rh positive blood not only fail to produce a rise in hemoglobin but may cause acute hemolytic transfusion reactions followed by an abrupt drop in hemoglobin (Wiener, A. S., and Peters, H. R.: *Ann. Int. Med.* 13:2306 [June] 1940. Wiener, A. S.: *Arch. Path.* 32:227 [Aug.] 1941). These observations can be explained as follows: The blood of every one contains, in addition to the agglutinogens characterizing the individual, one or more agglutinogens shared by all members of the species. Ordinarily an individual does not become immunized or sensitized against antigens contained in his own body, but under certain conditions this principle of "horror autotoxicus" of Ehrlich breaks down. For example, when the sensitized Rh negative patient is given Rh positive blood, he breaks the blood cells down. Then the body in disposing of the broken down cells may occasionally become sensitized to the common species antigens contained in the stroma. The resulting antibodies have the properties of reacting not only with the blood of other individuals of the species but also with the patient's own blood cells (i. e. they are autoantibodies) for the reason that the antigen in question is common to all members of the species. The antibodies then act on the patient's own cells, and a hemolytic anemia results. At times the patient's own broken down cells sensitize him further with resulting continued hemolysis, and unless this vicious cycle is broken death will result.

By extending this principle of "autoimmunization" by transfusion to pregnancy, just as isoimmunization by transfusion was extended to explain transfusion reactions in pregnancy, one arrives at a rather attractive explanation for the macrocytic anemias of pregnancy. If an Rh negative mother becomes oversensitized to the fetus's Rh positive cells, she may also form antibodies to one or more of the common species antigens, and an acute hemolytic anemia could result. In support of this hypothesis may be cited the following clinical facts (Whitby, L. E. H., and Britton, C. J. C.: *Disorders of the blood*, ed. 4, Philadelphia, Blakiston Company, 1942, p. 244): The disease begins rather abruptly between the sixth and eight months with serious symptoms of anemia and jaundice and other signs of hemolysis. The majority of cases have occurred in multiparas, and there is a tendency to recurrence in future pregnancies. Moreover, most authorities agree with Evans, who says that the anemia, once established, tends to recur in later pregnancies at an earlier date and grows progressively more severe with each pregnancy. These data are strongly reminiscent of erythroblastosis fetalis, and it is very striking that 3 cases that I saw recently all proved to be Rh negative.

Because of the rarity of the disease, it is naturally difficult to compile a large series in a short time. However, these limited findings are so strongly suggestive that it seemed worth while to report them at this time.

A. S. WIENER, M.D., Brooklyn.

To the Editor:—In commenting on the article by Dr. George V. Kulchar on the treatment of hemangiomas in his article on "Benign and Malignant Tumors of the Foot," which appeared in *THE JOURNAL*, March 18, Dr. C. Russell Anderson (*ibid.*, May 27, p. 302) makes statements that should not go unchallenged.

According to dermatologic opinion, although many such tumors may regress spontaneously, others may grow to unmanageable size and cause considerable disfigurement. If they do regress, residuals may remain. In 1 case of my experience on the head of a child a lesion the size of a finger nail remained untreated and at the end of a year was as large as a grapefruit and required four surgical procedures finally to reduce its blood supply, which at that time was enormous and was sufficient to cause hypertrophy of the child's heart. I would have been derelict in my duty had I advised the family not to have treatment, and it is my contention that early treatment of these cases is by far better than risking the changes brought about by delay.

It is my considered opinion that all angiomas sensitive to radiation should be treated from the day they are discovered if they show any tendency to grow.

MERLIN T-R. MAYNARD, M.D., San Jose, Calif.

TONSILLECTOMY IN POLIOMYELITIS

To the Editor:—The statement in the editorial in *THE JOURNAL*, July 8, that "the discrepancy in the statistics of Page and those of Stillerman and Fischer and of Aycock and others is no doubt due to the method of investigation" is somewhat misleading.

No one has claimed that tonsillectomy is frequently followed by poliomyelitis, nor has any one claimed that poliomyelitis is frequently preceded by tonsillectomy (figures collected to date show that bulbar poliomyelitis following tonsillectomy by an interval corresponding to the incubation period of the disease comprises about 1 per cent of all reported cases of the disease). Tonsillectomy is a common procedure and poliomyelitis a relatively rare occurrence. Page's finding of 1 case following 8,915 tonsillectomies would appear to be entirely consistent with the now generally accepted view that the avoidance of tonsillectomy during prevalence of poliomyelitis prevents the occurrence of numbers of cases of an extremely distressing and highly fatal form of the disease.

To be sure, large numbers of tonsillectomies must be avoided in order to prevent small numbers of cases. But it is the one preventive measure that can be used with assurance in poliomyelitis.

W. LLOYD AYCOCK, M.D., Boston.

ESTROGENIC SUBSTANCES

To the Editor:—Dr. H. Sheridan Baketel of Reed & Carnrick points out to me that the manner in which the table accompanying my article on the Clinical Use of Ovarian Extracts appearing in the May 6th issue puts one of its preparations in an unfavorable light. It implies that "Estrogenic Substances, R. & C." are made up as vaginal suppositories. Actually, this preparation is used only for oral and parenteral administration.

I am sorry that this error was made, and if it is possible for you to insert a short erratum making this correction it would be appreciated both by the firm concerned and by me.

C. F. FLUMMANN, M.D., San Francisco.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dental Practice Acts: Right of Board to Refuse to Reinstatement License Canceled for Failure of Licentiate to Pay Annual Renewal Fee.—Fischwenger was licensed after examination to practice dentistry in Florida in 1925 and as required by law renewed his license, paying the required annual renewal fees, annually thereafter in 1926 and 1927. In the latter year he left Florida, practiced elsewhere and never thereafter renewed his license in Florida. The law then in effect in Florida required each licentiate to renew his license annually, paying the required annual renewal fee prior to January 1, and provided for the automatic cancellation of a license if the licentiate failed to secure a renewal of his license prior to three months after December 31 each year. The law also provided, however, that a license that had been automatically canceled for this reason could be reinstated on application and the payment to the board of \$25. Fischwenger's license was canceled in 1928 for his failure to renew it. In 1941 an entirely new dental practice act was enacted in Florida (Laws, 1941, chapter 20240) repealing the previous dental practice acts and requiring in section 17 thereof that every licentiate renew his license annually on or before October 1. The new law provided for the automatic cancellation of a license of any licentiate who had failed to renew his license by December 31. The new act likewise contained a provision authorizing the renewal of the license automatically canceled on the payment to the board by the licentiate of \$25. Section 18 of the new act provided also

Upon the failure of any dentist to pay the annual renewal fee provided for in section 17 within two months after September thirtieth, the board shall notify in writing such dentist that such fees have not been paid, a second of such notices shall be sent by the board at the end of the fourth month, at the end of the fifth month after September thirtieth, if such fees remain unpaid, the board shall notify the delinquent by registered mail with return receipt attached that upon failure to apply for renewal certificate and to pay the required fees within the time specified in section 17 the delinquent must submit to an examination.

In 1943 Fischwenger applied to the board of dental examiners to have his license renewed without examination and tendered \$25. The board refused to renew the license previously canceled on the ground that, since Fischwenger had forfeited his privilege to practice in Florida by not keeping his license in force from year to year as required by law, he could not be restored to practice except on condition that he submit to a new examination. Fischwenger then brought mandamus against the individual members of the board to compel them to issue a renewal certificate to him to practice dentistry. From an order in favor of the defendant members of the board, Fischwenger appealed to the Supreme Court of Florida, Division B.

Fischwenger contended that one who has once been granted a license to practice dentistry under any dental law in force in Florida at the time of his admission to practice is privileged to renew that license at any time thereafter and without examination on the payment of \$25, unless prior to payment he has been served with notice by the board that unless such fees are paid within a certain specified time he will be required to take another examination as a condition to renewal, and the time prescribed by the notice has expired. We think, said the Supreme Court, that Fischwenger has misconceived the effect and intent of the provisions of the 1941 dental practice act referred to. The 1941 act, being an act comprehending the whole subject matter of the prior laws operated as a repeal of the earlier statutes to the extent that it revised or substituted new provisions therefor. By the terms of section 2 of the new act the privilege of practicing dentistry in the state of Florida was limited, after its passage, to those who were duly licensed and registered dentists under the laws of Florida at the time of the passage of the statute and to those who subsequently became duly licensed and registered as dentists pursuant to its provisions. The language of sections 17 and 18 of the statute has reference only to those persons falling within one or the other of the classes of persons described in section 2 of the 1941 act, it has no application to those persons who fall in any

other class. The only persons to whom the board is required to send delinquency notices under section 18 are those who were duly licensed and registered dentists under the laws of Florida at the time of the passage of the statute and who thereafter became delinquent, and those who, having subsequently become duly licensed and registered dentists under the 1941 law, thereafter fail to secure their annual renewal certificates within the time and manner prescribed by the statute. Fischwenger was in neither category. For it is clear that, immediately prior to the time the 1941 act became law, Fischwenger was not entitled to practice dentistry in the state, having forfeited that privilege by his failure to keep his license in force in accordance with the prevailing applicable statutes. At the time the 1941 act became effective his license to practice had long since expired by the limitations fixed by previous statutes in force at the time of its passage, and his right thereafter again to take up his profession in this state was subject to the conditions imposed by the new statute. The practice of dentistry in Florida is not an absolute unqualified or vested right but is a privilege that may be exercised only in subordination to the police power of the state. It may be controlled and regulated by the legislature in the exercise of the police power. When conflicts occur between the right of the citizen to follow such profession and the right of the state to preserve the general health and welfare, the right of the citizen in the matter must yield to the power of the state to prescribe such reasonable restrictions and regulations as may be necessary to protect the people from ignorance, incapacity, deception or fraud. Whatever may have been the conditions prescribed by the law prior to 1941 for continuing in the practice of dentistry, they did not prevent the state, at any time that the public good demanded, from making such further regulations and restrictions as to practice as the legislative authority deemed necessary or proper in the public welfare, so long as such further restrictions and regulations were reasonable and bore some just relation to the matter sought to be regulated. For reasons which were deemed sufficient by the legislature, the 1941 act was passed superseding previous statutes on the same subject and imposing new and more rigid requirements as a condition to continuation in practice. The statute abolished the privilege theretofore granted to delinquent dentists under the prior statutes to reinstate their licenses at any time without taking an examination. It is clearly within the authority granted to the state board of dental examiners by the legislature to require of Fischwenger an examination as a preliminary condition to the issuance of a renewal certificate. The decree in favor of the board of dental examiners was accordingly affirmed.—*Fischwenger v. York*, 18 So (2d) 8 (Fla, 1944)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Primary Atypical Pneumonia, Etiology Unknown.—Bacteriologic studies by Dingle and his collaborators at Camp Claiborne failed to reveal the etiology of this disease. In the routine cultures of the throats and sputums of patients with atypical pneumonia no bacterium stood out as a probable etiologic agent by reason of its occurrence or predominance. Evidence has not been obtained that fungi or rickettsias are etiologically associated with atypical pneumonia. The data obtained from anaerobic cultures are probably not sufficiently conclusive to exclude definitely the anaerobic bacteria. The results of the virus studies have provided interesting information regarding the probable distribution of some of the known viruses but have not indicated any one of them as the cause of atypical pneumonia. The data tend to exclude the viruses of influenza and the members of the psittacosis or ornithosis group (psittacosis, meningopneumonitis, lymphogranuloma inguinale). The syndrome was characterized by gradual onset, mild symptoms referable to the upper respiratory tract, distressing cough and moderately severe constitutional reaction. The character of the onset corresponded to that reported by others and differed from that of influenza and the bacterial pneumonias. Although few of the patients appeared as ill as patients with pneumococcal pneumonia, recovery from atypical pneumonia was more protracted. The average period of hospitalization was slightly longer than one month. Atypical pneumonia is one of the most important respiratory infections from the point of view of time lost from training. Atypical pneumonia was first recognized at Camp Claiborne during the course of a moderate epidemic. The disease probably had existed at the camp prior to this outbreak. Subsequent to the epidemic, the diagnosis was made with sufficient frequency to establish atypical pneumonia as one of the endemic respiratory illnesses. The high attack rate among the personnel of the station hospital is in agreement with the findings of other investigators, who observed a high incidence among physicians and nurses. The disease has been considered to be particularly common in adolescent and young adult white males, although the evidence for this cannot be considered conclusive. Almost all reports have emanated from institutions with young adult populations. Better opportunities for recognition of the disease and greater chances for close and repeated contacts in such institutions may explain these findings. In the few reports from general hospitals serving a more diverse population, cases have occurred in all age groups from childhood to advanced age, regardless of sex and race.

Successful Bronchoscopy for Atelectasis in 6 Hour Old Infant. D. D. Deeds and H. E. Bozer.—p. 711.

Endometriosis and Pregnancy.—Two patients with endometrial cysts complicating pregnancy were recently operated on at Johns Hopkins Hospital. The first patient, a 25 year old primigravida, was known to have an ovarian cyst early in pregnancy. She underwent an exploratory laparotomy at thirty-six weeks because of severe right lower quadrant pain. A ruptured right endometrial cyst and a left endometrial cyst were found. A 2,280 Gm. girl was delivered by cesarean section, and a subtotal hysterectomy, bilateral salpingo-oophorocystectomy, and appendectomy were done. The patient had six years of sterility, but she stated that she did not have dysmenorrhea, abnormal uterine bleeding, lower abdominal pains or other symptoms commonly associated with endometriosis. The probable cause of the rupture of this endometrial cyst was that the cyst was adherent to the uterus and, as the uterus enlarged, the adherent areas of the cyst thinned out until they became separated, allowing the contents of the cyst to escape. The second patient was a 23 year old woman who had a grapefruit sized endometrial cyst of the right ovary removed and a small endometrial cyst resected from the left ovary when ten to twelve weeks pregnant. The patient experienced lower abdominal discomfort for about one month before operation. She subsequently delivered a 2,390 Gm. boy in good condition during the thirty-fifth week of the pregnancy, and the placenta showed a small area of premature separation. The patient had no symptoms of endometriosis prior to the pregnancy. She had been married two years, and no contraception had been practiced. The sterility rate is high in patients with endometriosis, but the collected series of internal and external endometriosis cases complicating pregnancy is evidence enough that such patients can and do become pregnant. This fact should enhance the plea that, when the patient desires preservation of the child-bearing function, one should be conservative in the surgical procedure. Internal endometriosis (adenomyoma or adenomyosis) may cause an asymmetry of the uterus indistinguishable from myomatous changes or from a cornual pregnancy and may cause spontaneous rupture in pregnancy or may be the factor for uterine perforation at the time of therapeutic or criminal abortion. Internal endometriosis has caused uterine atony and postpartum hemorrhage. The tumor mass may cause dystocia. There is evidence that this type of endometriosis is an element in spontaneous abortions and miscarriages, ectopic pregnancies and placenta previa. External endometriosis complicating pregnancy is most commonly found in the cul-de-sac of Douglas. Ovarian endometriosis is the second most commonly reported type found during pregnancy. An ovarian cyst may be palpated, but unless there are complaints suggesting endometriosis the

fact that the cyst is endometrial will probably escape notice. The cyst may produce symptoms because of occasional leaking produced by increased countertension by the enlarging uterus on an already tense cyst.

Diethylstilbestrol in Inhibition of Lactation.—Walsh and Stronne report 190 cases in which breast feeding was either not desired by the woman or was contraindicated because of a dead baby, premature baby, flat or inverted nipples, heart disease, previous breast abscess, syphilis, tuberculosis or other conditions. Diethylstilbestrol was highly effective in preventing the development and minimizing the intensity of breast pain. Engorgement was reduced in incidence to one-third that of the controls; it was less intense and developed later in the puerperium. Lactation, while frequently delayed in onset, was definitely though less noticeably depressed than were the other features studied. Erythema was found in but one third the number of diethylstilbestrol treated cases, compared with controls. Fevers associated with breast engorgement occurred in approximately the same number of cases in each group. Entire freedom from breast pain and engorgement in the diethylstilbestrol treated series was striking in contrast with the control series. Conventional therapeutic measures were found to be of little benefit save in the partial reduction of lactation. Separate control studies on the therapeutic effect of diethylstilbestrol, once lactation had been established, showed that the treatment held but slight advantage in the relief of breast pain; that relief from engorgement and subsidence of lactation was definitely though not greatly bettered.

Resuscitation of Heart.—Barber and Madden state that if cardiac massage is performed before irreparable changes have occurred and if artificial respiration is maintained, recovery should occur. The percentage of complete recovery will vary in direct ratio to the time interval between cardiac stoppage and the production of an adequate circulation by massage. The maintenance of a free and adequate artificial respiratory exchange during the course of resuscitation of the heart is essential. Massage of the heart alone is of no avail if proper exchange of gases in the pulmonary alveoli cannot occur. Cases of cardiac stoppage susceptible of complete resuscitation are those resulting from asphyxia, reflex vagal inhibition, cardiac trauma, cardiac toxins (drugs, anesthetics) acute cardiac dilatation, hemorrhage and vasomotor paralysis with resulting circulatory insufficiency, and electrocution. The authors condemn the indiscriminate use of intracardiac injection of epinephrine or other sympathomimetic drugs. These drugs should not be administered during the course of cyclopropane anesthesia. Procaine hydrochloride 2 per cent, administered prior to or simultaneous with the intracardiac injection of epinephrine, lessens the possibility of ventricular fibrillation. Topical application of procaine 5 per cent, metycaine 10 per cent or cocaine 4 per cent may also be used to the surface of the heart; injection of 2 per cent solution into the chambers of the heart and electrical countershock are the most efficient methods in the treatment of ventricular fibrillation. The transthoracic approach is the method of choice in the performance of cardiac massage. Expo-

sure of the heart is obtained through a transverse incision in the left third or fourth interspace, the adjacent costal cartilages sectioned and the corresponding ribs widely retracted. Manual massage of the heart is the most effective means of initiating cardiac contractions. If uniform success is to be obtained, massage must be performed within three minutes after cessation of the heart beat.

Sulfonamides in Peritonitis of Appendical Origin.—Stafford and his collaborators made a survey at the Los Angeles County General Hospital of 903 consecutive cases of acute appendicitis with perforation or abscess formation. During the period from 1939 to 1942 inclusive the mortality rate for perforated appendicitis decreased from 9.2 to 3.4 per cent. Sulfonamides were used with increasing frequency, so that 98 per cent of all cases during 1942 received some form of chemotherapy. The mortality rate decreased each year as the use of sulfonamides increased. Morbidity as well as mortality was reduced, as observed by the yearly decrease in the frequency of post-operative peritoneal abscesses and pneumonitis. Drainage of the peritoneal cavity following appendectomy was used less often, as sulfonamides were used intraperitoneally in nearly all cases. In 1942 1 patient out of 3 had no drain used either in the *peritoneal cavity or abdominal wound*. In abscess formation following appendical perforation the procedure of choice was incision and drainage only in the completely walled off abscess. In 1942 appendectomy was performed in over three fourths of the abscess cases without fatality. Clinical observations in a large group of cases confirm the experimental evidence that sulfonamides are an effective form of therapy in the treatment of peritonitis. Their use is of particular value when implanted intraperitoneally during the early stages of peritonitis in perforative appendicitis.

Occlusion of Infected Patent Ductus Arteriosus with Cellophane.—As more patients with patent ductus arteriosus are being operated on, it is becoming obvious that the ordinary types of ligature material are inadequate to maintain occlusion of a patent ductus arteriosus. This is particularly true of the infected cases with large irregularly shaped vegetations within the lumen of the ductus arteriosus. Harper and Robinson report a case in which a patent ductus arteriosus was occluded by ligating it with two silk ligatures and then wrapping cellophane loosely about it. The patient was a woman aged 28 in whom a patent ductus arteriosus was complicated by long standing severe subacute bacterial endocarditis and endarteritis. The postoperative course demonstrated that the cellophane was responsible for the final complete occlusion of the patent ductus arteriosus. For the first two weeks the murmur and symptoms disappeared only to reappear and persist until two and one-half months had elapsed from the time of operation. The murmur and symptoms then completely disappeared and the patient has remained entirely well to date, one and one-half years after the ligation.

Sulfonamide Therapy of Actinomycosis.—Benbow and his associates state that approximately 90 per cent of the clinical cases of actinomycosis are caused by *Actinomyces bovis*. Reports indicate that sulfonamides are effective in the treatment of this disease. In most instances the sulfonamides were given in conjunction with potassium iodide. Ten per cent of cases of clinical actinomycosis are caused by aerobic *Actinomyces* or *Nocardia*. Some of these *Nocardia* are acid fast or partially

acid fast. Twenty-six cases of pulmonary infection with the acid fast type have been collected from the literature. The mortality is high: 25 of the 26 patients were dead at the time the reports were published. The authors report 2 new cases of pulmonary and chest wall infections with acid fast *Nocardia*. The first patient developed weakness and loss of weight. The x-ray film showed an infection of the left lung. Three draining sinuses appeared in the neck, chest and hip. Acid fast actinomycetes was found in the sputum and in drainage from the sinuses. After seven months' treatment with bed rest, vitamins, sulfonamides, x-ray therapy, surgical drainage and potassium iodide the patient made slow but steady improvement; she is now apparently well. The second patient developed an abscess in the subcutaneous tissues of the chest wall, followed by the appearance of multiple abscesses of the lung and a perirectal abscess. Acid fast actinomycetes was found in the sputum and in the perirectal abscess. With surgical drainage of the chest wall abscess, surgical and x-ray therapy for the perirectal abscess, supplemented by sulfadiazine and potassium iodide, the patient improved steadily. In actinomycosis sulfonamides do not give results analogous to those observed in pneumococcal pneumonia or meningococcal meningitis. Although temporary improvement nearly always follows their use, the authors have seen several cases of the anaerobic type in which the disease again became progressive and resulted in death. Actinomycosis is a chronic disease with remissions, spreads and generalized dissemination analogous to tuberculosis. Patients should be observed for a period of years rather than months before being classified as cured.

Atypical Pneumonia Simulating Pulmonary Tuberculosis.—Atypical pneumonia can produce lesions which at times are indistinguishable from pulmonary tuberculosis. Yoskalka observed 7 patients with upper lobe involvement among 96 patients with atypical pneumonia. Two of these had been roentgenologically diagnosed as having pulmonary tuberculosis. Conversely, 1 case had been diagnosed as atypical pneumonia which later proved to be tuberculosis. Approximately 7 to 10 per cent of atypical pneumonias have upper lobe involvement, the usual site for pulmonary tuberculosis. Serial roentgenograms showing apical lesions failing to clear in twenty days following the onset of the disease should raise the suspicion of pulmonary tuberculosis. Sputum studies for tubercle bacilli are indicated in all doubtful cases. If lesions persist for twenty days from the onset of the illness and routine sputum studies are negative, further studies should be done, such as sputum and gastric concentrates and guinea pig inoculation. Because of the apparent increase in the incidence of atypical pneumonia, the need for an early differential diagnosis is imperative.

Histaminic Cephalalgia and Migraine.—Lieder studied 71 consecutive patients with headache. Careful classification showed that 4 of these patients had histaminic cephalalgia, 52 had typical migraine and 15 had miscellaneous causes for their headache, such as hypertension and anxiety states. Histaminic cephalalgia is a vascular headache which is amenable to treatment with histamine. Its clinical characteristics are (1) absence of familial history of "sick" headache or allergic diseases, (2) onset most common in fourth or fifth decades, (3) short duration, (4) hemicrania usually, severe pain, constant, excruciating, burning, boring, (5) usually occurring during the night, (6)

eased by sitting up or standing erect, (7) associated with vasomotor phenomena consisting of lacrimation, congestion of the eye on the involved side, rhinorrhea or stuffiness of the nostril, increased surface temperature and often swelling of the temporal vessels of the involved side of the head, (8) attacks frequent, (9) compression of the common carotid and sometimes of the temporal artery frequently giving prompt relief, (10) occasional nausea, no vomiting, (11) no aura, (12) no relationship to the menstrual period, (13) alcoholic beverages frequently precipitating attacks, (14) histamine 0.1 to 1.2 mg. subcutaneously usually giving a typical attack of unilateral pain identical with the spontaneous attack, (15) epinephrine 1:400,000 solution, intravenously, giving prompt relief, (16) cure by hypsensitization to histamine. The efficacy of histamine hypsensitization therapy in histamine cephalalgia was confirmed in 2 patients. In 28 of the 52 patients with migraine, food allergy was found. Twenty-three of these patients exhibited other major allergic diseases such as hay fever, urticaria and asthma. A positive family history of allergy or migraine was obtained in 40 patients. Hypersensitivity assumes a major role in causing migraine. In the prophylaxis of migraine, identification and elimination of offending allergens, usually foods, is important. Physical and mental strain, which are predisposing factors, should be avoided. Ergotamine tartrate 0.25 to 0.50 mg. given subcutaneously is by far the best and simplest therapeutic agent.

Asbestos Corns.—Derwatz in 1930 directed attention to warts and corns on the hands and feet of persons who worked with asbestos and described the discovery of an "asbestos needle" in the cornified layer of tubercles removed from the hands. Alden and Howell observed small painful "warts" or "corns" in 99 of 167 workers who used amosite, a natural form of asbestos, in their work in a navy yard. The workers who have these lesions complain of an original pricking sensation and ability to feel a small splinter-like foreign body. Rough attempts to extract this splinter-like body are usually unsuccessful, but with rubbing or with neglect the sensation tends to disappear. In about ten days a small hard cornlike tumor appears, which slowly grows, often attaining the size of a small split pea. Frequently a pinpoint black center, which defies extraction, can be observed in the excrescence. At this period the small cornified tumor is tender to pressure, as though a splinter were present, and interferes with comfortable work. Cornification becomes more pronounced, a small hard corn resulting, and the area does not become normal in appearance and feeling until the hard center plug is removed by instrumentation. These corns usually appear on the tips of the fingers and knuckles, most often occurring in the thick skinned areas of the hands. X-ray examination does not reveal abnormal shadows. Biopsy specimens from 4 patients revealed no pathologic changes except extreme thickening of the surface epithelium with hyperkeratosis. The dermis, while fibrous, was essentially normal in appearance and did not present any evidence of inflammation. Despite diligent search, foreign bodies could not be found in the sections. Observations and history of symptoms imply, however, that a foreign body is at some time present in the lesions. There is no relation to abcesses of the lungs. No satisfactory method of prevention can be offered.

Blast Injury of Ears.—Silcox and Schenck say that, of 1,922 casualties classified as having traumatic or surgical injuries and admitted to a hospital ship during the Solomon Islands campaign, 82, or 4.2 per cent, had blast injury of the ears serious enough to warrant observation and treatment by the otolaryngologist. Many patients had varying degrees of aural damage from concussion waves, but blast injuries of a more serious character to the thoracic or the abdominal viscera of these patients precluded extensive aural study. They were not included in this series. The commonest type of aural lesion was traumatic rupture of the tympanic membrane with or without secondary infection. Other forms of aural damage included traumatic deafness, which was almost universally present in varying degree, hemorrhage into the middle ear cavity, dislocation of the ossicles and labyrinthine hemorrhage. The precipitating causes for aural damage were (a) atmospheric blast arising from the detonation of aerial bombs, large caliber shells, mortar shells, hand grenades and land mines and (b) immersion blast from detonation of depth charges when the subject was in the water. Forty-one of the 82 patients gave a history of exposure to blast waves from bombs, and of this group 11 were unconscious following the concussion. Fifty-eight patients had perforation of the tympanic membrane. Suppurative otitis media was present at the time of admission in 35 of the 82 patients. As infection developed in such a high proportion of the patients without the technical error of syringing, it might be prudent to suggest the prophylactic measure of applying locally microcrystals of sulfathiazole as soon as possible after traumatic rupture has occurred. When secondary infection does not supervene, a traumatic perforation of the drum membrane heals promptly. Occasionally both the hearing and the tinnitus can be improved by inflation of the eustachian tube, particularly when the tympanic membrane is intact. Deep diathermy, concentrated vitamin B and rest are adjuvants. If there is superimposed suppurative otitis media, the insufflation of microcrystalline sulfathiazole powder or the instillation of a suspension of this drug into the external auditory canal will promptly control the infection.

New Approach to Recurrent Malaria.—The tendency of malaria to recur after seemingly adequate therapy led Drewyer and Hughes to investigate what could be accomplished in preventing recurrence of symptoms. At the United States Naval Convalescent Hospital at Glenwood Springs, Colo., there is a natural hot vapor cave which is heated by a hot mineral water spring. The temperature of the spring is 140 F. The temperature in the cave varies between 102 and 110 F., with a relative humidity of 87 to 93 per cent. Patients are treated in the cave for a total of twenty minutes in divided periods, ten minutes at first with a three minute rest, then seven minutes

with a three minute rest and finally three minutes. The average oral temperature rise is 2 to 3.4 degrees. The patients are then brought upstairs and placed on a plinth; they are wrapped in a sheet and wool blanket and allowed to cool gradually for half an hour. Patients are treated daily. In latent malaria, when the plasmodium remains in the stagnant capillary beds of the spleen, liver and other organs, the artificial raising of the systemic temperature causes a general capillary dilatation with discharge into the peripheral circulation of red blood corpuscles with the dormant plasmodium, which within a period of twenty-four to ninety-six hours results in a typical malarial paroxysm. After a positive blood smear for the plasmodium is obtained, therapy is instituted in the form of quinine sulfate, 36 grains (2.4 Gm.) in three divided doses daily. Drug therapy is continued until the patient is afebrile for five days and the blood smear is negative for malaria. The patient is then returned to the department of physical medicine for five more fever sessions in the hot vapor caverns. During this time he continues to take quinine at the same dosage. The quinine is then stopped and the fever sessions are continued for six days. Whereas with ordinary treatment 8 of 26 patients had a recurrence, following the combination of artificial pyrexia and drug therapy there has been no recurrence of symptoms.

Undisplaced Fractures at Ankle Joint.—Cleveland and his associates point out that rigid immobilization for fracture at the ankle joint, whether accompanied by displacement or not, was the rule. The most frequent bony injury about the ankle joint involved the distal one fourth of the fibula at the external malleolus or slightly above it in the fibular shaft. The convalescent—out of plaster—phase was frequently longer than the time of immobilization. This period was characterized by persistent dependent swelling, pain on weight bearing with crutches, and limitation of motion. Many of these patients had the partial use of their extremity throughout the immobilized period by attached or incorporated walking devices. For this type of injury a revision of treatment was instituted. Immobilization was discarded in favor of bed rest, elevation, ice packs and early active mobility. Weight bearing with crutches was permitted on subsidence of the soft tissue damage. All such treated cases needed no manipulation. The security of the ankle joint mortise was proved by x-ray studies. The impression was that the group of nonimmobilized patients recovered more rapidly than did the immobilized ones. The records of 32 external malleolar fractures without any or with minimal displacement which were treated with a circular plaster of paris dressing were contrasted with a similar number which received the bed rest and non-immobilization routine. The average period of hospitalization and duty days lost by the immobilized patients was 57.3 days. For the nonimmobilized patients the duration of hospital stay was 35.7 days.

Gastric Ulcers Produced by Injection of Caffeine.

Roth and Ivy employed the technic of embedding caffeine in a beeswax-liquid petrolatum mixture in order to obtain prolonged and continuous caffeine action. The mixture was prepared in batches of 22.5 Gm. of anhydrous caffeine alkaloid, 15 cc. of melted bleached beeswax and 60 cc. of hot liquid petrolatum. The mixture was injected alternately into the shoulder, thigh, calf and back muscles of 22 cats, which weighed from $3\frac{1}{2}$ to $7\frac{3}{4}$ pounds (1,588 to 3,518 Gm.) and were given 300 mg. of caffeine base daily. Eleven of the 22 cats developed bleeding erosions or ulcers. All of the mucosal defects appeared in the lesser curvature of the stomach, in the antral and prepyloric regions. The stomachs contained black-brown stained material and showed numerous punctate bleeding points surrounding the ulcers. Grossly the mucosal defects resembled those occurring spontaneously in man. The acute and subacute bleeding erosions and ulcers observed in the gross specimens were confirmed and studied in detail in microscopic sections. The microscopic picture suggests that the vasodilatation and engorgement might

in turn give rise to stasis, increased capillary permeability, transudation and impaired cell nutrition, all of which would contribute to the development of ulceration. The experiments imply that the excessive use of beverages containing caffeine might assume a contributory role in the pathogenesis of gastroduodenal ulcers in man. In view of these findings and the pronounced stimulation of gastric secretion in man by the oral or parenteral administration of caffeine, it is suggested that the use of caffeine beverages be restricted in the management of the peptic ulcer patient.

- B Vitamins in Beef.—Cover and her associates point out that the vitamin content of meat usually has been reported on the raw basis. Heat losses during cooking may be expected. Rare roast beef is cooked to a lower internal temperature than

well done beef and has lower weight losses in the oven. Since these factors may affect the retention of the B vitamins, it seemed desirable to determine the losses of thiamine, riboflavin, nicotinic acid and pantothenic acid in rare and well done beef, roasted by a method which not only is suitable for use in the home but could be controlled carefully enough for research purposes. Right and left two-rib roasts of beef were cut alike and used as pairs, one being analyzed raw and the other after cooking by a standardized method. The entire meat in each roast was ground and samples were used for the determination of thiamine, riboflavin, nicotinic acid and pantothenic acid. The average vitamin content of eighteen raw roasts from the commercial carcasses was, in microgram/Gm, thiamine 1.3, riboflavin 1.5 and 1.6 by the fluorometric and microbiologic methods respectively, nicotinic acid 49 and pantothenic acid 4.9. Differences in vitamin content between the raw rib roasts within a carcass were not significant for any of the four vitamins, but differences between animals were highly significant. Retentions in rib roasts of beef, rare and well done respectively, were thiamine 75 and 69 per cent, riboflavin 83 and 77 per cent, nicotinic acid 75 and 79 per cent, pantothenic acid 91 and 75 per cent. *Retentions of thiamine and pantothenic acid were significantly lower in the well done than in the rare roast, but with riboflavin and nicotinic acid the differences between rare and well done roasts were not significant.* One serving of rib roast of beef was calculated to furnish approximately 7 per cent of the thiamine, 6 per cent of the riboflavin and 37 per cent of the nicotinic acid recommended for a moderately active woman for one day.

Action of Atabrine on Electro Cortico Potentials.—Pick and Hunter studied the reaction of the brain cortex to varying doses of atabrine. They made their investigations on cats and frogs. They found that atabrine in doses of 5, 10 and 12 mg. per kilogram given intraperitoneally or intravenously can alter the electrocorticogram of cats in pentobarbital sodium anesthesia. The rapid wave frequency usually disappeared, and only slow waves of low amplitude remained. This central depressant action of atabrine seems to be independent of the atabrine blood concentration and appears to be related to the atabrine content of the brain. This effect persisted, depending on the dose given, for one to four hours. A similar atabrine action was seen in the electrocorticogram of pithed frogs following the injection of atabrine. The authors conclude that their results tend to support clinical observations of central disturbances occurring during or following the administration of atabrine.

Meningoencephalitis in Lymphogranuloma Venereum.—Zarafonetis presents evidence that lymphogranuloma venereum may be a cause of acute meningoencephalitis. He reports 2 cases. A virus was isolated from an inguinal lymph node of 1 patient five months after the onset of illness, in spite of the fact that the histopathologic changes in the lymph node were nonspecific. The virus was identified as lymphogranuloma venereum. Mice were immunized to this virus and to another strain of lymphogranuloma venereum by intraperitoneal injection. Subarachnoid block, an extremely high total protein and first zone colloidal gold curves were observed. Positive Frei tests were obtained on 1 patient with an antigen made from the virus isolated from him as well as with other yolk sac antigens. An intradermal test on the same patient with psittacosis antigen was negative. The etiologic relationship of the virus to the meningoencephalitic changes was based on the involvement of the central nervous system, the knowledge that this virus can produce meningoencephalitic signs in experimental animals, the fact that the virus has been isolated from the spinal fluid of other patients with the disease and the negative serologic results in tests against other encephalitis-producing virus agents. Final proof that lymphogranuloma venereum can cause meningoencephalitis in man must await isolation of the virus from the brain substance in a fatal case and the demonstration of microscopic changes in the brain tissue consistent with those produced by the virus in experimental animals. On the basis of the spinal fluid dynamics, the first patient presented a complete spinal block throughout the eight months he was observed. It is believed that the meningeal involvement early in the course of his illness resulted in subarachnoid block. This syndrome is known to occur in patients with acute purulent meningitis, tuberculous meningitis, yeast meningitis and syphilitic meningitis. Since these causes were excluded by cultural and serologic studies, it appears probable that the adhesive arachnoiditis was a residuum of the lymphogranuloma venereum infection.

Filariasis.—Michael directs attention to the growing incidence of filariasis among marine and navy personnel returning from the South Pacific. The present study deals with lesions caused by *Wuchereria bancrofti*. *Wuchereria malayi* has apparently not been identified in any of the patients. Filariasis is a nematode infection present in tropical and semitropical areas of the world. The Samoan variety differs in lacking the nocturnal periodicity of the microfilariae. Several thousand thick and thin smears taken at various intervals during both day and night hours have proved to be negative for microfilariae. Correlating these findings with the studies made on lymphatic tissue of the patients lends support to the belief that microfilariae will probably not be demonstrated in appreciable numbers, if at all. Unquestionably at some time in the cycle of the parasite microfilariae were present in the circulating blood. It is obvious that this problem is far different from that observed in endemic areas where large masses of the native population are infected and microfilariae may be demonstrated in the blood at will. It is hazardous to guess what might have happened in 4 of the author's patients from whom lymph nodes were removed and adult female pregnant *W. bancrofti* worms recovered. The possibilities are decidedly lessened when the optimal factors of tropical humidity and temperature are removed by change to temperate climates. Man is the definitive host, and approximately 44 different mosquitoes may serve as host for development of the mature larvae (intermediate host). The most common intermediate hosts are *Culex quinquefasciatus* and *Aedes scutellaris*. Other less common transmitters are *Culex pipiens*, *Aedes rossii*, *Aedes variegatus* and *Anopheles costalis*. Although the symptom free period may vary greatly from one or two months to twelve months, the majority of the author's patients developed their first symptoms from seven to nine months following their initial exposure. Constitutional symp-

toms consist of chills, mild fever, general malaise, nausea and occasional photophobia. Patients frequently note painful swollen red areas in the extremities which later involve the adjacent lymph nodes, followed by a retrograde or centrifugal lymphangitis. A vast majority of the patients show a funiculitis with or without epididymitis, orchitis or hydrocele. The author gives a detailed description of the histopathologic changes and thinks that the importance of serial sections of lymph nodes cannot be overemphasized. From microscopic studies and the fact that he was unable to demonstrate microfilariae in the peripheral blood stream, he concludes that this disease will not become a public health problem in this country. Filariasis should be ruled out in certain atypical lymph node diseases. Lymph node and lymphatic channel biopsies of the upper extremities cause no harm and afford the best means of diagnosis. Many of the lesions of filariasis are believed to be allergic in nature as the result of filarial foci elsewhere in the body. Certain lymph node, testicular and spermatic cord enlargements, together with the so-called fugitive swellings of the skin, may be explained on this basis. No specific effective therapeutic agent has as yet been demonstrated.

Dried Plasma Sheets for Burns and War Wounds.

Pollock introduces a new method of treating burns which apparently overcomes many of the objections found with tannic acid, triple dye and other coagulants. The ideal coagulum should be durable, noncontractile, indefinitely pliable, nontoxic, nonirritant, resistant to trauma, bactericidal, painless and not unsightly and should contain fibrin. Dried plasma sheets apparently come closer to fulfilling these criteria than any other coagulum introduced. The plasma sheets were made in a Petri dish, giving a sheet 4 inches in diameter. To 20 cc. of sterile water in a Petri dish, 1.5 to 2 Gm. of dried plasma is added and dissolved, and 0.2 Gm. of sulfanilamide powder added. This preparation is dried in an oven at 140 C. until a firm sheet forms. This drying process requires fifteen to twenty minutes. It is then allowed to cool and is applied directly to the burn. It was felt that second degree burn should have layers of tissue paper thickness, and deeper wounds should have thicker layers. The plasma sheets tend to curl at the edges. This curling can be overcome by moistening the sheet with water before applying. Within a few moments the plasma sheet becomes adherent, and within a few hours strands of fibrin can be seen securing the plasma sheet to the burn. Plasma loss is stopped immediately. Dressings may be used but are not essential. Plasma sheets were used also in the treatment of indolent, ulcerating slow healing war wounds.

Food Poisoning.—Breese and his associates describe seven outbreaks of acute food poisoning in a large naval training station. In five the causative food was determined and in three bacteriologic confirmation was secured. The foods that cause illness are those which make good mediums for the growth of organisms and are generally of animal origin (meat, fish or dairy products). In addition they have usually undergone considerable handling in the preparation after the initial cooking and have been rewarmed just prior to serving or have been served cold. Foods in these categories are ham, creamed chicken or fish, meat, fish or chicken salads, croquettes, hashes and goulashes, cream filled pies and pastries. The usual deviation from the proper technique of food handling is in permitting the sliced or boned meat or the prepared food to stand for several hours at room temperature or in inadequately refrigerated ice boxes before it is served. Rewarming is insufficient, but thorough re cooking just prior to serving will, despite improper handling, destroy the organisms and their toxins. The staphylococcus enterotoxin is said to withstand boiling for thirty minutes. The author outlines measures designed to prevent food borne disease.

Penicillin in Treatment of Certain Diseases of Skin. I. A. Roxburgh, R. V. Christie and A. C. Roxburgh.—p. 524.

Laboratory Control of Penicillin Treatment. L. P. Garrod.—p. 528.

Surgery and Penicillin in Mandibular Infection.—The first group of 4 cases reviewed by Mowlem involved postoperative cases in all of which infection was either anticipated or was causing early reaction. In these cases 1,000 units of penicillin was injected daily for several days and there was early bacterial control with consequent normal healing. The second group comprised 16 cases of osteomyelitis of the mandible. In all of them infection has been gross and well established, and penicillin has been used in conjunction with radical surgery. The operation consisted in subperiosteal excision of the lower border of the bone, together with the outer plate and all the infected medullary area. Until the advent of penicillin, the overlying soft tissues of the cheek were then packed away from the bone and the cavity allowed to granulate from its depth. The sulfonamides did much to control infection, but packing still seemed necessary. When penicillin became available, it was decided to continue this radical surgery with closure of the soft tissues. This has three advantages: (a) The soft tissues of the cheek may be closely approximated to the underlying bone and can be expected to contribute to vascular ingrowth. (b) The closed cavity not only excludes secondary infection but also retains the penicillin, which is thus permitted to exercise almost continuous action. (c) Primary instead of delayed healing is obtained. There was considerable similarity between all the cases. A soldier presented a 2 months' old sinus in the iliac crest, with induration of the surrounding tissues. Hemolytic streptococcus and Staphylococcus aureus was found, and 1,000 units of penicillin was injected daily for ten days with improvement in the surrounding soft tissue but no change in the sinus or its bacteriologic contents. At operation a small sequestrum was found in a cavity lined with fibrous tissue. From this case the author deduces that, even if sterility is obtained with penicillin, healing will not automatically follow. The fibrosis and its resultant avascularity are the determining factors, and not the infection, and this will be true of many established bone infections. Penicillin is therefore no substitute for adequate surgery.

Penicillin in Bone Infections.—Robertson explored the value of penicillin in 34 cases of bone infections. In a group of 7 cases of hematogenous osteomyelitis, all in children, with one exception penicillin was used as an adjunct to surgery. The wounds following surgical exploration were packed lightly with petrolatum gauze and enclosed in a plaster, a window being cut to allow inspection and taking swabs for culture. Systemic penicillin treatment was given by various routes, dosage being calculated roughly according to body weight and based on an adult dose of 120,000 units daily. Local application of penicillin was employed in 8 cases of chronic hematogenous osteomyelitis and 7 cases of osteomyelitis following compound fractures. The results of the local application of penicillin have been disappointing. Complete healing occurred in only 1 of these cases. In the others there was only temporary or no improvement. The author lists the following three factors as probably responsible for the unsatisfactory results: (1) failure of continuous application, (2) inaccessibility of the bone infection, (3) the presence of dead bone. In the group of compound fractures, those cases presenting a guttered wound with gross skin loss and bare bone exposed in the depths were particularly resistant to treatment, the mixed bacterial flora remaining

unaltered and the healing of the wound being delayed. It is hoped to improve on these discouraging results by the more radical removal of infected bone, followed by complete closure, if necessary with the aid of a full thickness graft, and subsequent instillation of penicillin solution through a tube. Of 12 patients with miscellaneous orthopedic defects 10 were treated with the local administration of penicillin and 2 with the systemic application. The majority of the locally treated cases in this miscellaneous group responded well, possibly because the lesions were of small extent, involving mainly soft tissues, and usually not of long standing. The 2 cases treated systemically were costly failures. To judge by the results in these 2 cases, long standing sepsis involving bone must be considered an unfavorable field for penicillin treatment, either local or systemic.

Medical Journal of Australia, Sydney

1:237-260 (March 18) 1944

Health and the Gold Standard. J. Dale.—p. 237.

*Management of Established Wound Infections. H. R. G. Poate.—p. 242.
Kationic Chemotherapy, with Special Reference to Acridines. A. Albert.—p. 245.

Management of Wound Infections.—Poate believes that little attention is given to the control of frank suppuration. One reason for this is the abuse of the "closed plaster" technic. Once patients have reached a base hospital where they can be retained, plaster casts should be abandoned in the majority of cases. The nauseating stench of foul wounds which characterized the primitive hospitals of pre-Lister days, and a reversion to "laudable pus," have no place in the modern treatment of infected wounds. The all pervading and sickening odor of stinking plaster permeated with blood and pus has a depressing and even demoralizing effect. The continued loss of plasma protein in running pus has a debilitating effect on the patient, and the chronic toxemia with its associated pyrexia has a harmful effect on the constitution of his blood and on his tissues generally. Plaster is invaluable in providing comfort during transport and has proved to be a life saver in many cases, but it should not be abused. Poate is chiefly concerned with deep wounds and especially with those associated with bone and joint injury. He stresses the following points in the management of established wound infection: the great importance of maintaining the hemoglobin content of the blood as near to normal as possible; the necessity for removal of all dead tissue and especially sequestrums from the depths of these wounds; the abolition of closed plaster technic in these cases once a stabilized form of treatment is available; the inefficiency of sulfonamides as local applications in the presence of frank pus; the great importance of the acridine antiseptics in the control of established and chronic sepsis; the necessity for maintaining the skin surrounding wounds in a surgically clean condition so as to prevent reinfection; the control of cross infection in hospital wards.

Bollettino d. Soc. Ital. d. Med. e Ig. Trop., Asmara

2:5-114 (No. 6) 1943. Partial Index

*Rheumatic Fever in Eritrea. G. Ferro-Luzzi.—p. 13.

Modes of Onset and Course of Pulmonary Tuberculosis in Ethiopians.—p. 48.

Rheumatic Fever in Eritrea.—Ferro-Luzzi studied 50 white Europeans who were living in Eritrea and presented symptoms of rheumatic fever. There were no cardiac complications in a group of patients in whom the first attack of the disease occurred when the patients were living in Eritrea or presented a recurrence of a first attack in Eritrea. Cardiac complications were observed in a group of patients in whom the attack of the disease represented a recurrence of previous attacks suffered in Europe. One of the patients in the first group died from an acute hyperfebrile form of the disease. The heart was found to be normal at a necropsy. Salicylates, iodine, arsphenamines, sulianilamide, sodium glycerophosphate and short wave therapy failed in patients in the former group, whereas they were effective in those of the second group. The natives do not have the disease. Laboratory studies and cultures failed to reveal the etiologic agent in the patients of the first group. The author believes that the disease is a form of rheumatic fever.

Book Notices

New and Nonofficial Remedies, 1944, Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1944. Issued Under the Direction and Supervision of the Council on Pharmacy and Chemistry of the American Medical Association. Cloth. Price, \$1.50. Pp. 778. Chicago: American Medical Association, 1944.

Noteworthy features of *New and Nonofficial Remedies, 1944*, are the revision to put into effect the Council's decision to use the metric system exclusively and the addition of the chapter on contraceptives. In the opinion of many the decision to use only the metric system will appear to be the belated taking of a step which has been long overdue. Nevertheless it represents a courageous move on the part of the Council. It is to be hoped that the Council's action will hasten universal adoption of this system in this country. Concession is made to those who may be still attached to the apothecary system in the form of the excellent equivalent dosage tables which appear in the front part of the book.

The chapter on contraceptives is quite comprehensive; with the acceptance of more preparations it will undoubtedly assume a large place in *New and Nonofficial Remedies*. The Council has thus far accepted some contraceptive jellies and creams, contraceptive diaphragms, diaphragm inserts, syringe applicators and fitting rings. It is understood that a number of additional preparations have been submitted for Council consideration since the book went to press. This chapter again represents a courageous and long needed innovation.

Some of the new preparations that appear in this volume are Succinylsulfathiazole, a new sulfonamide, a proprietary brand being "Sulfasuxidine"; Diodrast Concentrated Solution, a preparation of the already accepted Diodrast for use in a special diagnostic procedure for visualization of the circulatory system and also cholangiography; a preparation of Sodium Benzoate for use as a liver function test; Mersalyl and Theophylline, accepted under the name Salyrgan-Theophylline Tablets, proposed as an adjunct to intravenous injection of the already accepted drug; Zinc Insulin Crystals and Zinc Insulin Injection Crystalline; Tetanus Toxoid, and Concentrated Oleovitamin A and D, a dosage of the Pharmacopeial preparation.

A glance at the preface shows that certain general articles have been revised to bring them up to date. More or less important revisions have been made of the chapters on barbituric acid derivatives, estrogenic substances, parathyroid, ovaries, sulfonamide compounds and vitamins, especially the sections on vitamin B complex and vitamin D. In this connection it is worth noting that each chapter in the book is reviewed annually, or more often if indicated, by the responsible referee for such revision.

One notes the curtailment of the section on "articles and brands accepted by the Council but not described in *New and Nonofficial Remedies*." It is understood that this is caused by the recent decision of the Council greatly to limit its list of official preparations and to describe in the body of the book such of the listed articles and brands as it seems necessary to retain. This again appears to be a somewhat radical and forward looking decision of the Council. Such innovations and leadership are to be commended, and the new and younger members of the Council will undoubtedly pursue these and other objectives with the same sane and competent leadership that has distinguished this body and its service to the medical profession and to society in general.

Clínica psiquiátrica. Por el Dr. Ernesto Daniel Andía, jefe del Servicio de neurología del Hospital Municipal de Avellaneda "Pedro Fiorio." Paper. Pp. 583, with 123 illustrations. Buenos Aires: Editor Aniceto Lopez, 1944.

This is a well written and complete textbook on clinical psychiatry. It is excellently illustrated and contains many good diagrams. It consists of thirteen chapters, on early conceptions, psychologic applications in psychiatry, the patient's clinical history, the patient's psychiatric findings, psychic constitutions, manic depressive syndrome, confusional states, deliriums, schizophrenia, dementias, oligophrenic syndrome, epilepsy and alcoholism. The book is up to date and is recommended to psychiatrists who have a reading knowledge of Spanish.

A Text-Book of Histology Arranged Upon an Embryological Basis. By J. Lewis Bremer, M.D., Hersey Professor of Anatomy, Harvard University, Boston. Rewritten by Harold L. Weatherford, Ph.D., Assistant Professor of Anatomy, Harvard University. Sixth edition of "Lewis and Stöhr." Fabrikoid. Price, \$7. Pp. 723, with 598 illustrations. Philadelphia: Blakiston Company, 1944.

This textbook has well merited its position as one of the most important books for medical students since its first appearance, thirty-eight years ago, as the sixth American edition of "Lewis and Stöhr." That edition was written by the eminent scholar Dr. Frederic T. Lewis and has the distinction of being the first book of its kind arranged on an embryological basis. The emphasis of its contents has always been on the necessity of an understanding of the development of each organ described as an introduction to the study of the microscopic structure in the adult. This point of view has proved to be efficiently sound and has enriched the teaching of histology in American medical schools. In the course of time this fundamentally sound idea captured the attention of other authors. Today the consideration of the developmental possibilities of the constituent tissues of adult organs is accepted as common sense pedagogy. Dr. Frederic T. Lewis performed a great service for anatomy in this country in initiating and fostering this vital interpretation of histology. In the same spirit Dr. John L. Bremer presented and enlarged the book through three editions.

The present edition offers a comprehensive discussion of the essential facts of histology. It is rewritten by Dr. Harold L. Weatherford, who by training, experience, pedagogic understanding and the gift of clear, precise writing is unusually well qualified to deal with this subject matter. The author has made available to teacher and student alike the functional concept of histology; he has admirably succeeded in summarizing the recent greatly expanded experimental work in histology and embryology.

There are several distinguishing features in this edition. First there appears an excellent succinct account of the development of the microscope, a careful reading of which will profit each student. Second, there are more than 750 references covering classical as well as modern works. The interpolation of historical citations throughout the book serves to place the textual material in its proper cultural milieu. Among these references one will find the names Aselli, Bichat, Cicero, Corti, Harvey, Hooke, Kircher, Leeuwenhoek, Mascagni, Schleiden, Schwann, Willis, Winslow and Wolff in addition to the names of von Baer, Bartholin, Bell, Diemerbroeck, Eustachius, Fabricius, Fallopius, Malpighi, Pecquet, Ruysch and Vesalius, which were included in the fifth edition. Such historical references find a fitting place in a book which sets a high standard of scientific achievement and should make a strong impression on students who have an appreciation of scientific humanism. Third, the illustrations have been almost doubled, about fifty in color and all particularly well chosen to meet the needs of students. Fourth, the present editor was fortunate in having the special section on the shape of cells written by Dr. Frederic T. Lewis and the section of placenta written by Dr. George B. Wislocki.

The dynamic point of view adopted in the presentation of the contents will unquestionably make a strong appeal to students of medicine, for whom this book was originally planned, forming a sound basis for the study of both physiology and pathology. It will serve equally well, however, the requirements of students of biology not alone as a textbook but also as a tool of research.

The Romance of Medicine: The Story of the Evolution of Medicine from Occult Practices and Primitive Times. By Benjamin Lee Gordon, M.D., Attending Ophthalmologist to the Shore Memorial Hospital, Somers Point, New Jersey. Cloth. Price, \$3. Pp. 624, with 147 illustrations. Philadelphia: F. A. Davis Company, 1944.

This is a learned work about the history of medicine, excellently illustrated and arranged according to a special plan. The book is badly titled, because the author has missed a great deal of what is romantic and dramatic in the development of medicine. However, his chapters on the location of the vital energy, demonology, astrology, symbolism, magic and occult healing condense much material that is not easily available in a single chapter elsewhere. Indeed, the work partakes far more of the philosophy of medicine than of romance. For the subject it discusses it is a most valuable addition to works on the history of medicine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ALUMINUM COMPOUNDS FOR SILICOSIS

To the Editor:—Is there anything to the claim that aluminum dust is an antidote for silica dust and that silicosis in workers can be prevented by treating them with aluminum dust?

M.D., Troy, Ohio.

ANSWER.—Amplly confirmed experimental evidence both in Canada and in this country proves that inhaled metallic aluminum and amorphous aluminum hydroxide will completely neutralize the toxic action of quartz on living tissue. Given prophylactically before the quartz tissue reaction, it will limit the process to simple phagocytosis with no subsequent fibrosis; given after the quartz, aluminum and its amorphous hydrate will arrest the development of silicosis and cause resolution of immature nonfibrous lesions. Treatment does not dissolve silicotic nodules that have already attained maturity. Experience in North America fails to confirm the German reports that aluminum produces any serious effects on the lungs. A limited clinical experience indicates that some cases of silicosis are relieved of symptoms by aluminum therapy. It remains to be proved whether or not certain nonsilicious materials often associated with quartz in industrial dusts may interfere with the inhibitory action of aluminum. Theoretical and clinical evidence suggest that they may and thus may explain some of the failures that have been reported.

PREGNANCY IN WOMAN WITH DOUBLE UTERUS AND CERVIX

To the Editor:—A woman aged 29 who is in her eighth month of pregnancy has a double uterus and a double cervix, which malformation probably corresponds to the uterus bilocularis as illustrated in De Lee's "Principles and Practice of Obstetrics," 1940, page 593, or to the double uterus with double cervix of Taylor, as quoted on page 192 of the 1943 Year Book of Obstetrics and Gynecology. An anteroposterior vaginal septum was removed following spontaneous abortion at two and a half months about two years ago, the septum having been discovered prior to the first pregnancy. The first pregnancy was in the left uterus, and apparently this pregnancy is in the same side. Although I am treating the patient expectantly, I am aware of some of the antepartum as well as the postpartum complications. The Year Book of Obstetrics and Gynecology, 1943, mentions some of them, although it makes no suggestions as to the proper treatment of these cases. I am also aware of the fact that a good many women with similar malformations have gone through labor normally. When the miscarried nearly three years ago she had a severe hemorrhage following the expulsion of the placenta, for which hemorrhage she had to have a blood transfusion. My patient has just finished her eighth month of pregnancy, and it would be highly appreciated if you would please refer this case to an authority on the subject. Pelvicmetric measurements appear to be normal. The patient has always been moderately anemic (hypochromic, normocytic anemia). Would it be advisable to perform a conservative cesarean section as soon as labor starts if the fetus is viable? Would you please give opinions of the proper authorities?

M.D., Wisconsin.

ANSWER.—A patient like this should be treated expectantly just as a patient who has a single uterus and a single vagina. An elective cesarean section is definitely not indicated. Dys-tocia does not occur frequently enough in such cases to warrant this radical procedure as the method of choice. In De Lee-Greenhill's Textbook of Obstetrics (ed. 8, Philadelphia, W. B. Saunders Company, p. 534) expectancy is the treatment recommended for this type of case. Stander (William's Obstetrics, ed. 8, p. 712) says that ordinarily there is no interference with the course of pregnancy, and spontaneous labor may be looked for. Much more rarely the nonpregnant horn may block the pelvic cavity and give rise to dystocia similar to that produced by tumors of other origin. Of course, in such cases cesarean section must be performed. Palmer Findley (*Am. J. Obst. & Gynec.* 12:318 [Sept.] 1926) collected 132 cases of uterus didelphys from the literature and added 3 of his own. All represented a complete doubling of the uterus, cervix and vagina and all the patients had been pregnant. These 135 women had 217 full term babies. In 83 cases spontaneous delivery occurred, in 23 cesarean section was performed, 22 women were delivered by forceps or version and extraction, and so on.

In women with this abnormality, abortions are fairly common and labor is prolonged as a result of poor muscular development in the uterus, small rigid cervix and the encroaching

nonpregnant uterus. Since spontaneous delivery is the rule, the management of pregnancy and labor in the uterus didelphys should not differ from that of pregnancy in the normal uterus save in the event of complications.

TRICHOMONAS WITH MIXED VAGINAL FLORA

To the Editor:—In a case of a mixed infection involving and causing a severe leukorrhea in which both *Trichomonas hominis* and *Escherichia coli* have been identified, what laboratory method might be used to identify *Trichomonas hominis* in the stool? In this case, in which the intestinal flora has been altered by the prolonged use of bismuth beta-naphthol, *Escherichia coli* could be obtained from the vagina, the cervical canal and the external meatus. What medication can be recommended for the destruction of *Escherichia coli*, at least to the extent that it would not be so abundant as to cause uncomfortable symptoms of itching and mucosal irritation of the external urethral meatus and the vaginal mucosa? Does the presence of either *Trichomonas hominis* or *Escherichia coli* alter the vaginal acidity? If so is there any concept as to how the clinician may use the altered acidity? I would appreciate also some references.

M.D., New York.

ANSWER.—Considerable controversy still exists on whether *Trichomonas hominis* can cause vaginal trichomoniasis. Some maintain that it is solely an intestinal inhabitant. The clinical entity of vaginal trichomoniasis in association with *Trichomonas vaginalis* is established. It is quite possible that more than one species of tetratrichomonads may be found in the lower bowel. Thus the necessity for appropriate cultural and morphologic studies are evident.

Escherichia coli may be found frequently in the vagina and vulva. Consequently its presence about the external urethral meatus does not establish pathogenicity. If the urinary tract is completely normal and free from infection and the cervix is perfectly normal, the colon bacilli will disappear as soon as a normal healthy vaginal condition is restored. The normal healthy vagina during the reproductive period of life (excepting at the time of menstruation and shortly after delivery) is normally acid. There is no established incidence of pathologic hyperacidity of the vagina. The vagina in a healthy state is associated with a great preponderance of vaginal bacilli or Doederlein's bacilli. It is agreed by most workers that the pronounced acidity is related to the carbohydrate content of the vaginal epithelium and normal physiologic bacterial action. *Trichomonas vaginalis* presumably will not survive in a pH environment of 4.5, and sharper acidities seem unfavorable to the colon bacilli.

It is assumed that the organism *Trichomonas hominis* mentioned may be *Trichomonas vaginalis*, but in any event the use of alpha or beta lactose in tablets or capsules daily for from two to six weeks and gradual reduction as improvement occurs will produce a high incidence of favorable responses. Douches, table salt (4 tablespoons to 1 quart of water) or alum (1 heaping teaspoon to 1 quart of water) may be used once weekly. Douches are not very effective therapeutically and remove the evidence without correcting the cause. Where there are focal infections in the patient's urethra or bladder or in the cervix, appropriate therapy to these sites may be necessary to prevent recurrence.

The attempt to alter the acidity by acid douches has been successful in some investigators' hands, but an excessive acidity may be detrimental to the normal bacterial flora. The normal vagina will develop its own healthy state unless there are factors which prevent it.

XANTHINES FOR CORONARY DISEASE

To the Editor:—Is there any evidence that, in the treatment of coronary disease either before or after infarction, the type of xanthine series drugs ought to be changed frequently or at all? For example, if the patient is taking aminophylline for two months or so is there any advantage in changing over to some other type of drug of this series?

M.D., Wisconsin.

ANSWER.—On the basis of experimental and clinical observations, it is likely that prolonged administration of xanthines or habitual use of coffee or tea will often confer a relative diuretic unresponsiveness to xanthine derivatives. However, little is known with regard to the coronary action of these drugs. The controversial literature on this subject has been critically

Dr. Robert Helly Library

U. S. Medical College

39657

reviewed by Boyer (THE JOURNAL, May 29, 1943, p. 306) under the recommendation of the Council on Pharmacy and Chemistry. The evidence that xanthine derivatives exert any favorable influence on experimental and spontaneous coronary disease was found to be inadequate and inconclusive. Obviously before the coronary action of xanthines is elucidated nothing can be stated with finality on the development of fastness to these drugs.

APHAKIA

To the Editor.—An aphakic eye requires about a plus 10.0 sphere correction. Is this all due to the replacement of the lens by a corresponding increase in the volume of the aqueous or has the distance from the anterior to the posterior pole of the eye been decreased? Textbooks give the index of refraction of the lens as from 1.386 to 1.406 at the core and of the aqueous as 1.336. This does not seem to be enough to shift the second principal focus by 4 mm. Is the length of the eyeball increased on accommodation?

M.D., Pennsylvania.

ANSWER.—The changes in aphakia apparently are due to the removal of the lens and not to the replacement of the lens by a corresponding increase in the volume of the aqueous or a decrease in the distance from the anterior to the posterior pole of the eye.

The lens in normal position is equivalent to a +20 D. lens (Gullstrand's schematic eye is 19.11 D and Tscherning's lens is 21.39 D.), but when the lens is removed it requires only an approximately +10. D. lens to correct an eye which was emmetropic. This is mainly because of the fact that the lens is placed 13 mm. anterior to the cornea, which greatly enhances its action. There are two principal reasons why a +10 diopter lens placed before the eye is equivalent to the +20 diopter lens of the eye. One is the increase of the focal distance, i. e. from the lens to the retina, and secondly the lens placed before the eye has a much greater relative refractive index. The lens in air has a relative refractive index of 1.345 to 1, while the ratio of the average effective index of the lens, 1.44, to that of aqueous and vitreous, 1.336, is much less. Divers must have special lenses because their vision becomes blurred when submerged in water. The water has practically the same index of refraction as the aqueous. Fishes overcome this by having an almost spherical lens. An estimate of the correction of an aphakic eye can be obtained by adding +10.00 D. to one-half the power of the required glass previously necessary to neutralize existing ametropia.

There are a number of theories concerning the accommodation of the eye. According to the Helmholtz theory, accommodation is caused by relaxation of the zonule, which permits the lens to become more convex. In the Tscherning theory traction on the zonular fibers is postulated and the lens becomes more convex because of the resistant nucleus and structure of the anterior capsule. Most authorities believe that the accommodative act merely produces change in the curvature of the lens and do not believe that the length of the eyeball is increased in accommodation.

ANAL INSTILLATIONS AFTER HEMORRHOIDECTOMY

To the Editor.—Following the surgical removal of internal hemorrhoids in which raw surfaces remain in the anal canal and lower rectum, would instillation of 30 cc. of 1 per cent aqueous solution of mercurachrome result in sufficient absorption to cause toxicity? Would mercurachrome used in the lower rectum following hemorrhoidectomy have any bacteriostatic property? Following hemorrhoidectomy would 30 to 60 cc. of 2 per cent aqueous solution of sodium chloride instilled in the lower rectum have any bacteriostatic property?

Lieutenant Colonel, M. C., A. U. S.

ANSWER.—The procedure outlined would not be toxic unless the patient is sensitive to the drug. The drug would not be bacteriostatic since there would be little contact with the denuded areas which are within the anal canal. The solution of sodium chloride would not be bacteriostatic, although it might have some mechanical cleansing value.

PROGRESSIVE MUSCULAR ATROPHY

To the Editor.—Will you give me information on the treatment of progressive muscular atrophy? I have under treatment a middle aged man who for the past two years has shown a progressive atrophy of the muscles of the right upper extremity. During the past few months atrophy of the right thigh has been noted. Muscular twitches have been noticed frequently. He has received thiamine hydrochloride 100 to 200 mg intramuscularly and intravenously twice a week. He has been taking vitamin E synthetic 200 mg. daily by mouth, also vitamin A 100,000 units daily by mouth.

Edward H. Weiser, M.D., Sussex, N. J.

ANSWER.—Besides the use of vitamins, particularly vitamin E, and thiamine, already used in the case described, there have been no additional forms of treatment suggested recently for progressive muscular atrophy.

PERSISTENT LACTATION

To the Editor.—A white primigravida, primipara, aged 30, married, had a normal pregnancy, delivery and postpartum period four years ago. She nursed her child for eight months and since then has had a continuous profuse flow of breast milk. She feels perfectly well and is able to work in a war plant and do her own work at home. She had scarlet fever, measles and chickenpox between the ages of 2 and 8. There have been no serious illnesses since then except for an occasional upper respiratory infection. One year ago she was treated for obesity and states that she lost 20 pounds (8 Kg.) in six months. At that time she was given injections, the content of which is unknown, and oral medication consisting either of thyroid or of amphetamine. The menarche began at 12, periods last from twenty-eight to thirty days; there is a three to five day flow, normal in quantity, with a slight dysmenorrhea. There has been no change in menstruation in the past four years. There is no similar lactation history in the rest of the family. The breasts are large, firm and pendulous, without masses; the nipples are erect, with moderate pigmentation of the areola. A thick, white, milky secretion appears of the nipple ducts on slight manipulation. The heart rate is 72 per minute, with regular rhythm. There are no murmurs or enlargements. The blood pressure is 130/80. There is a slight laceration of the cervix; the uterus is normal in size, shape and position; the adnexa are normal. The red blood count is 4,900,000, hemoglobin 85 per cent; the white blood count, 7,400; polymorphonuclear cells 72 per cent, lymphocytes 18 per cent, eosinophils 2 per cent, basophils 1 per cent and monocytes 7 per cent. No basal metabolic test has been made.

M.D., New York

ANSWER.—Except for the patient being overweight, the information conveyed in this query shows that the woman is normal. Her menstruation is normal. There is no record of her basal metabolic rate. Obesity has nothing to do with this continued lactation.

It might be well to give the patient 25 mg of testosterone propionate every other day for six injections. Then one should wait two weeks to see what effect this has on lactation. If it checks the flow, she does not need any further treatment. If there has been no change at the end of two weeks the treatment should be repeated as before.

If the full twelve injections are necessary it may be best to have more information on the patient or to know what reaction she had from the testosterone before more treatment is given.

There are some treatments for lactation which date previous to the advent of endocrinology, such as that with belladonna. These can be found in a good book on gynecology.

MALIGNANT NEPHROSCLEROSIS AND CHRONIC GLOMERULONEPHRITIS

To the Editor.—Could you please refer me to any literature or pathologic reports concerning the superimposition of malignant nephrosclerosis on a kidney previously suffering with chronic diffuse glomerulonephritis?

Copton, M. C., A. U. S.

ANSWER.—The following articles cover the subject of the association of malignant nephrosclerosis and chronic glomerulonephritis:

Horn, Henry, Klemperer, Paul, and Steinberg, M. F.: Vascular Phase of Chronic Diffuse Glomerulonephritis, *Arch. Int. Med.* 70:260 (Aug.) 1942.

Derow, H. A., and Altschule, M. D.: Nature of Malignant Hypertension, *Ann. Int. Med.* 14:1768 (April) 1941.

Ellis, Arthur: Natural History of Bright's Disease, *Lancet* 1:1 (Jan. 3), 34 (Jan. 10) 72 (Jan. 17) 1942.

Mansfield, J. S., Mallory, G. K., and Ellis, L. B.: Differential Diagnosis of Bright's Disease, *New England J. Med.* 229:387 (Sept. 2) 1943.

THERAPY OF BONE LESIONS OF MULTIPLE MYELOMA

To the Editor.—A man with multiple myeloma suffered a fracture of the twelfth dorsal vertebra and the right clavicle about eight months ago. The x-ray examination shows that these have healed, but he is still in considerable pain in his back and is very weak. He is confined to bed most of the time. Is there any treatment that will help him?

S. Ross Jones, M.D., Port Arthur, Texas

ANSWER.—Roentgen therapy to the areas shown to be involved in the x-ray films usually results in relief of pain. Because of their radiosensitivity the bone lesions of multiple myeloma generally respond favorably and often heal following roentgen therapy.

CONTRACEPTION AND STERILITY

To the Editor.—Will you please tell me whether or not modern methods of contraception are a cause of future sterility or disability.

M.D., New York.

ANSWER.—There is no evidence that modern methods of contraception such as the diaphragm with jelly, jelly alone, suppository or sponge with foam powder are a cause of future sterility or disability.

PENICILLIN

ITS USEFULNESS, LIMITATIONS, DIFFUSION AND
DETECTION, WITH ANALYSIS OF 150 CASES
IN WHICH IT WAS EMPLOYED

WALLACE E. HERRELL, M.D.
DONALD R. NICHOLS, M.D.
AND
DOROTHY H. HEILMAN, M.D.
ROCHESTER, MINN.

The introduction of penicillin for treatment of bacterial infections is one of the most important developments in chemotherapy. The relative lack of toxicity of penicillin for most tissues is one of its great advantages. This lack of toxicity was apparent to Fleming¹ and to Florey and his associates.² It was further evident from studies carried out in our laboratories, which began early in 1941,³ that penicillin was a highly antibacterial substance and at the same time possessed very low toxicity for tissue as measured by means of tissue culture methods. Although penicillin is exceedingly effective in treatment of some infections, it is ineffective against many others. One of the essential requirements for successful treatment of bacterial infections with penicillin is to limit its use to infections due to those pathogens which are known to be susceptible. At present the susceptible and the insusceptible organisms are essentially those listed in table 1. As the work progresses, other organisms undoubtedly will be added to the list.

The successful use of penicillin is attended by other problems not commonly encountered in the use of therapeutic agents. Penicillin therapy should be confined to institutions as long as it is necessary to administer the material intravenously or intramuscularly. Penicillin cannot be administered by mouth, because it is destroyed by the gastric acids. Neither can it be administered intracolically, since it is destroyed by certain organisms present in the fecal stream.

The large scale preparation of penicillin has been accompanied by many difficulties which have necessi-

tated careful control of release of the material. Because penicillin is extremely labile, it must be protected during its preparation against heat, changes in the pH of the surrounding mediums, oxidizing agents and certain micro-organisms which elaborate substances which result in loss of potency of penicillin.

METHODS OF ADMINISTRATION

Local Application.—The broth filtrates of cultures of *Penicillium notatum* which contain penicillin were applied locally by Fleming¹ as early as 1929. In 1940 the Oxford investigators² reported the successful preparation of a purified penicillin which proved suitable for experimental studies and for treatment of infections due to susceptible organisms. Both the sodium and the calcium salts have been used for local treatment, but the calcium salt is more satisfactory. For local treatment of wounds involving soft tissue and bone and for topical application to infected surfaces, saline solutions containing 250 Oxford units per cubic centimeter are suitable. Recently the British investigators⁴ have used penicillin locally in two other forms: 1. If a dry substance is desired, weighed amounts of penicillin are ground with sulfanilamide in a mortar until a homogeneous powder results. On occasions the final mixture contains as much as 5,000 Oxford units of penicillin per gram. The report by Ungar⁵ suggests that penicillin and sulfonamides may have a synergistic effect. 2. Another preparation which the British have applied locally is a cream containing lanette wax, which contains 100 to 250 units of penicillin per gram.

In treatment of severe and extensive inflammatory lesions, uniformly satisfactory results are more likely to be obtained by systemic penicillin therapy alone or this in combination with local therapy.

Intrathoracic Instillation.—In treatment of suppurative intrathoracic disease, such as empyema, it is desirable to supplement parenteral therapy with instillation of penicillin into the pleural space. In many instances empyema thus can be satisfactorily treated without resorting to surgical drainage. For this purpose, as a rule, 30,000 to 40,000 Oxford units in 30 to 40 cc. of isotonic solution of sodium chloride can be instilled directly following thoracentesis. This procedure is carried out once every twenty-four to forty-eight hours.

Intra-Articular Instillation.—Recently our studies have indicated that fairly adequate antibacterial amounts of penicillin reach the joint fluid following intramuscular or intravenous administration of the material to patients suffering with acute or subacute suppurative disease of joints. The concentration of penicillin in the joint fluid is in some instances approximately half that in the blood. If it is desirable to supplement systemic therapy, however, instillation of penicillin into the joint

is not accompanied by any serious effects. We have instilled as much as 20,000 Oxford units in 10 cc. of isotonic solution of sodium chloride directly into a septic joint after aspiration has been performed. Studies on the length of time that penicillin will remain in the joint following instillation are mentioned later.

TABLE 1.—Antibacterial Action of Penicillin

<i>Pittacusis virus</i>	
<i>Ornithosis virus</i>	

Intrathecal Instillation.—It will be evident, when diffusion of penicillin into the various tissues is considered, that in treatment of meningitis or infections involving the cerebrospinal structures it is essential to supplement systemic therapy by daily instillations of 10,000 to 20,000 Oxford units of penicillin into the spinal canal. This amount of penicillin usually is dissolved in 10 cc. of isotonic solution of sodium chloride. Both the sodium and the calcium salts of penicillin have proved satisfactory for this method of administration.

Subcutaneous Administration.—Penicillin may be administered intermittently or continuously by subcutaneous infusion. However, absorption of subcutaneous fluids is erratic and variable. Moreover, concentrated solutions of penicillin may be irritating when given subcutaneously. It appears, therefore, that the intravenous or intramuscular method of administration is preferable.

Intramuscular Administration.—Intermittent intramuscular administration of penicillin is a simple and practical method. Every three hours, 10,000 or 20,000 Oxford units, in 2 to 4 cc. of isotonic solution of sodium chloride is injected. A standard 20 gage intramuscular needle $2\frac{1}{2}$ inches long is suitable. Local irritation may occur occasionally, and at least eight injections in twenty-four hours are required. The concentration of penicillin in the blood rises rather sharply during the first hour following intramuscular administration and then falls to a very low value during the hour before the next injection is made (fig. 1). Such rather sharp rises and falls of the concentration in the blood of any antibacterial agent are not, as a rule, desirable in the treatment of bacterial infections, particularly severe, overwhelming sepsis.

Intravenous Administration.—Penicillin disappears from the blood even faster after a single intravenous injection than after a single intramuscular injection. Further, intermittent intravenous injection requires eight separate venipunctures per day. This method has been used, however, in some instances with satisfactory results.

The continuous intravenous drip method of administering penicillin, which is used at the Mayo Clinic, has been described elsewhere.⁶ The dose of penicillin given in twenty-four hours by this method has varied considerably with different investigators. For treatment of some types of infection, many investigators believe that administration of 200,000 to 300,000 Oxford units per day is necessary. We have used, as a rule, no more than 80,000 units per day and, in many instances, 40,000 units. When increased supplies of penicillin are available, the problem of dosage may become of less significance. In our early work with penicillin, low doses were employed to spread a small supply of penicillin as far as possible. If subsequent experience indicates that the hazard of delayed recurrence is increased by using low dosage, obviously the amounts used must be increased. We consider, however, that 100,000 units per day is probably the maximal amount of penicillin necessary for treatment of the infections most commonly encountered. Delayed recurrence, in the presence of metastatic lesions, may occur at times regardless of the amount of penicillin used.

Local venous irritation at the site of injection may attend use of the continuous drip method. It seems especially likely to occur with certain batches of penicillin which probably contain impurities. Careful inspection of the intravenous apparatus, and changing the site of injection at the first sign of irritation, usually are sufficient to cope with this difficulty. Although we have administered penicillin for as long as eight days through the same vein and at the same site of injection often it is necessary to change the apparatus every few days. In our experience, venous irritation does not occur in more than 5 to 10 per cent of cases.

The continuous intravenous drip method is used by us almost entirely except when suitable veins are not available. Under these circumstances the intermittent intramuscular method is used. It is our impression that approximately twice as much penicillin is required for satisfactory intramuscular treatment as is required when the intravenous drip method is employed.

Fig. 1.—The falling serum concentration of penicillin in three hours when 50,000 units is administered by intramuscular injection and the approximately constant serum concentration when the same amount is given by continuous intravenous drip over the same period.

DIFFUSION OF PENICILLIN INTO VARIOUS TISSUES

Historical.—The test of the amount of active penicillin in the blood can be measured by the power of the blood serum to effect bacteriostasis. This is the test

6. Herrell, W. E.: The Clinical Use of Penicillin, an Antibacterial Agent of Biologic Origin, J. A. M. A. 124: 622-627 (March 4) 1944

which lies behind use herein of the terms "penicillin activity," "bacteriostatic activity," "concentration of penicillin" in the blood or in the tissue fluids, "blood level of penicillin," "penicillin content" and so on.

Florey and his associates⁷ made the first report on distribution of penicillin in the body after it had been administered in different ways. From studies with experimental animals they found that penicillin disappeared rather rapidly from the blood after a single intravenous injection but that a large percentage of the amount administered was found in the urine. When penicillin was given by subcutaneous injection, the concentration in the blood was less but a detectable amount was present for a longer period than after a single intravenous injection. Penicillin, when administered by any route, was found in a more concentrated form in the bile than in the blood serum, but the total amount excreted by the liver was small compared with that excreted by the kidneys. Penicillin was absorbed from the intestine when care was taken to protect the penicillin from being acted on by the acid of the stomach. Regardless of the method of administration, penicillin was found in the saliva in lower concentrations than in blood collected at the same time. Tears, pancreatic juice and spinal fluid had no antibacterial activity when penicillin was given intravenously. When a single intravenous injection of penicillin was given to human patients there was an initial high level of penicillin activity in the blood, followed by rapid loss of activity; large amounts of penicillin were excreted in the urine. When penicillin was introduced into the small intestine by means of a duodenal tube, the substance was found in the blood for a longer period than after a single intravenous injection. Penicillin also was detected in the blood after it had been given by mouth along with adequate amounts of sodium bicarbonate.

The Floreys,⁸ reporting further clinical experiences with penicillin, included data on the presence of penicillin in the blood. Rammelkamp and Keefer⁹ and Rammelkamp and Helm¹⁰ extended to human patients the observations made by Florey and his co-workers on experimental animals. In addition, Rammelkamp and Keefer found that when penicillin was injected into inflamed body cavities such as a knee joint, a suprapatellar bursa or an empyema cavity, or when it was introduced into the cerebrospinal fluid, it could be detected in the blood and it was found to be present for as long as twenty-four hours in the region into which it had been injected. There was some evidence that penicillin passed more rapidly from the cerebrospinal fluid into the blood when the meninges were inflamed than when they were not.

Fleming¹¹ reported quantitative determinations of the bacteriostatic power of blood and cerebrospinal fluid of a patient with streptococcal meningitis who had been treated with penicillin. In another study Fleming¹²

described a technic to determine the blood levels of penicillin that result from intravenous and intramuscular injection of different amounts of penicillin. He showed that the presence of leukocytes along with specific antibodies for the test organism added to the bacteriostatic power of the blood when penicillin was present. Thus he was able to explain why a favorable clinical result may occur even though penicillin cannot be detected in the blood by any of the methods available at present. Fleming also found that when penicillin was injected into an axillary abscess its presence could be detected in the abscess twenty-four hours later.

Present Work.—Since it has been demonstrated by others that intermittent intravenous injections of penicillin are not satisfactory for maintaining an adequate level of penicillin in the blood, further investigations were not made along this line. We were interested particularly in determining the penicillin activity of the blood of patients who were receiving penicillin by the continuous intravenous drip method, which has been used, for the most part, in our clinical studies. Using Fleming's adaptation of the Wright slide cell technic, determinations were made on one specimen from each of 11 patients who were receiving 40,000 units a day by continuous intravenous drip. The serum of 6 of these patients gave a value of 0.12 unit per cubic centimeter; in the serum of 1 was 0.06 unit per cubic centimeter, the serum of 2 contained 0.03 unit per cubic centimeter and there was no penicillin in the serum of 2 patients. The blood of 1 of these last 2 patients gave no evidence of activity on three different occasions. When this patient was given 100,000 units of penicillin a day by continuous intravenous administration, the amount of penicillin present in the blood serum was 0.12 Oxford unit per cubic centimeter. In the blood of another patient who was receiving 80,000 units a day by intravenous drip also there was 0.12 unit per cubic centimeter.

A study was made of the penicillin activity of the blood following intramuscular injections. Three patients were given 50,000 units of penicillin by intramuscular injection every three hours, and the bacteriostatic activity of the blood was determined at hourly intervals. The results are presented in figure 1. Even with the comparatively large amounts of penicillin administered, the blood taken one hour after injection did not contain more than 1 unit per cubic centimeter. Significant amounts of penicillin were detected in the blood throughout the period of treatment.

The amount of penicillin in the urine varied greatly with a number of factors. Some of the conditions influencing the results were the amount of penicillin administered, the volume of urine excreted and the presence or absence of bacteria in the urine. The presence of coliform bacteria was accompanied by rapid loss of penicillin activity when the specimen was kept at room temperature. On several occasions urine which contained coliform bacteria and in which the concentration of penicillin was high soon after being voided (as much as 120 units per cubic centimeter) completely lost its penicillin activity after being kept in the icebox overnight.

What is now to be said relates to an earlier paragraph on intrathecal instillation. The observation of Rammelkamp and Keefer that penicillin does not pass from the blood into the spinal fluid in detectable amounts was confirmed. Four persons were given 100,000 units of penicillin a day by continuous intravenous administration. Two specimens of cerebrospinal fluid were

taken from each patient while this treatment was in progress but none gave evidence of penicillin activity. When 10,000 units of penicillin was administered intraspinally, penicillin activity could be detected in the spinal fluid twenty-four hours later. Values varied from a trace of penicillin to 0.06 unit per cubic centimeter.

Fig. 2.—Columns represent penicillin found in blood: black columns, mother's blood; shaded columns, blood from umbilical cord. In the different cases 100,000 units of penicillin was administered at different intervals before delivery. In case 1 the interval was forty-five minutes, in case 2 fifteen minutes and in case 3 five minutes. In case 3 both mother's blood and blood from the umbilical cord gave positive complement fixation tests for syphilis.

Forty-eight hours after intraspinal administration of 10,000 to 20,000 units, no penicillin could be detected. Determinations were made three times on each of 3 patients.

In a consideration of the advisability of using penicillin in the treatment of antepartum syphilis, it is of importance to know to what extent penicillin given to the mother will pass into the placental circulation and become available to the fetus. Consequently, three observations were made on human subjects. A large amount of penicillin (100,000 units) was given during a relatively short time to each of 3 patients toward the end of the second stage of labor. At delivery, a short time later, a sample of blood from the umbilical cord and a sample of blood from the anterior cubital vein of the mother were obtained simultaneously. In 1 instance blood from the mother and that from the umbilical cord both gave positive serologic tests for syphilis. The results of these tests are presented in figure 2. It is evident from these studies that penicillin is transmitted through the placenta and is available to the fetus whether the pregnant mother is without evidence of disease or whether she has syphilis.

SUITABLE METHODS FOR DETERMINING THE PRESENCE OF PENICILLIN IN BODY FLUIDS

We have studied various methods described by others of determining the presence of penicillin in body fluids.¹³ Also we have attempted to develop methods that would be more sensitive and more reliable than those used at present.

A number of determinations of penicillin activity were made on various body fluids, using both Fleming's

method and that of Rammelkamp on the same specimens. The same amount of penicillin standard usually caused inhibition of bacterial growth in both tests, but there was often a difference between the two tests of one dilution in either direction. Tests of penicillin activity of blood serum and other body fluids frequently gave different results by the two methods.

In order to determine which method was more reliable, known amounts of penicillin were added to human serum in the laboratory of Dr. Fordyce Heilman and the mixtures were tested as unknowns by both methods. In preparing the samples, normal human serum was divided into five portions. To one portion was added 1 cc. of 0.85 per cent sodium chloride solution for each 4 cc. of serum. A similar proportion of 0.85 per cent sodium chloride solution was added to each of the other portions but, previous to the addition, a different amount of penicillin had been mixed with each quantity of sodium chloride solution and the actual concentration in each instance was recorded. Small amounts of each mixture were put into glass tubes, numbered by code and stored in carbon dioxide. A few tubes were taken at random each day for a period of several days to be tested as unknowns by one of us (D. H.). The standard used in the tests was the same preparation used in making the unknown serum-penicillin mixtures. The results of these experiments are presented in table 2.

Fleming's method was found to be reliable for determining the actual penicillin content of serum.^{13a} The percentage of variation between the results obtained with the slide cell technic and the actual penicillin content did not exceed the 50-per cent variation that is to be expected when serial dilutions are employed. The presence of a large proportion of serum did not decrease the sensitivity of the test in detecting small amounts of penicillin. Fairly small amounts of penicillin (0.06

* Samples were run as unknowns.

unit per cubic centimeter) were not detected by Rammelkamp's method and the results obtained were less uniform than those obtained with Fleming's test. In determining the penicillin content of the blood it is frequently desirable to be able to detect rather small amounts if they are present. It would seem that the Fleming test is superior in this respect to other quantitative methods available at present.

13a. The details of the method will be published elsewhere.

Fleming's method has certain other advantages. It is not necessary to use sterile technic in performing the test and material to be tested does not have to be filtered to insure sterility if it is tested soon after it is received. When the slide cell method is performed with micropipets very small amounts of the fluid to be tested are necessary and but little equipment is needed. The end point is easily determined, and the entire test is complete in eighteen hours. In the Rammelkamp test it is recommended that some of the contents of a few tubes near the end point be cultured on blood agar to insure sterility. This requires an additional twenty-four hour period in order to complete the test.

ANALYSIS OF RESULTS IN 150 CASES

Including the first case reported from the Mayo Clinic in which penicillin was used,¹⁴ we have employed penicillin in the treatment of 150 patients suffering from infections owing to a variety of pathogenic bacteria. The present report deals with the results in these cases. The sodium salt of penicillin was used in 103 of the 150 cases. Two of us (W. E. H. and D. R. N.¹⁵)

was started. With 1 or 2 exceptions, all of these 28 patients were given the daily dose of penicillin previously recommended by us. In only 1 instance was there evidence of a delayed metastatic lesion which might possibly have been associated with the use of inadequate amounts. This case will now be reported:

A woman aged 20 was admitted at the clinic five days after onset of her illness, which had followed self-inflicted trauma to a furuncle on the chin. Subsequent to this trauma, extensive cellulitis had involved the chin, face and neck. Her temperature suddenly had risen to 105 F. Blood taken by her local physician had revealed *Staphylococcus aureus* on culture. She had been treated intensively with sulfadiazine. In spite of this the cellulitis had progressed rapidly and blood cultures had remained positive.

At the time of the patient's admission, the blood culture revealed 10 colonies of *Staphylococcus aureus* per cubic centimeter. The woman was unable to open the mouth or to swallow. She received 60,000 units of the calcium salt of penicillin daily by the intravenous drip method for nine days (total 540,000 units). A blood culture obtained twenty-four hours after use of penicillin had been started revealed 1 colony of *Staphylococcus aureus* per cubic centimeter. Blood cultures taken forty-eight

Fig. 3.—a, appearance of patient at onset of penicillin therapy. Extensive cellulitis of mouth and face with extension into the cervical tissues. *Staphylococcus septicaemia*. Edema and cellulitis have practically disappeared. Complete recovery.

have reported previously on the calcium salt of penicillin. We have found it entirely satisfactory for local, intravenous, intramuscular and intrathecal use. It can be kept at room temperature for long periods without evidence of loss of activity. In studies¹⁶ of cytotoxicity carried out in our laboratories, several preparations of the calcium salt proved less toxic than samples of the sodium salt tested in a similar fashion. The calcium salt was used in 47 of the cases herein reported.

Bacteremia.—At the time of preparation of the present report we had used penicillin in 28 cases of bacteremia. One of these cases will be counted again among the cases of meningitis. The organism identified in 25 of these cases was *Staphylococcus aureus*. An anaerobic streptococcus was isolated in 1 case, hemolytic streptococci in 1 and *Neisseria intracellularis* in 1. The sodium salt of penicillin was used in 16 of the cases and the calcium salt in 12. Twenty-five of the 28 patients recovered satisfactorily (89 per cent). The 3 patients who failed to recover all died of acute vegetative endocarditis and all had presented suggestive evidence of endocarditis at the time penicillin therapy

hour after administration of penicillin had been started were negative, and three subsequent cultures were also negative. The temperature reached normal on the sixth day and remained normal thereafter. There was regression of the edema of the soft parts, and ninety-six hours after treatment had been started the patient could open the mouth without difficulty and was able to take a normal diet (fig. 3 a, b and c). On the twelfth day after admission, the patient was dismissed from the hospital and returned to her home. She felt well and made no complaints.

Several days after the woman had returned home, according to her account, she contracted a chest cold and a productive cough developed. She had a slight chill and a temperature of 103 F. and she also complained of pain in the left side of the thorax. She was treated with sulfamerazine by her local physician but, because of the persistence of her cough, she was readmitted at the clinic eighteen days after her dismissal. Blood cultures on readmission were negative. The bacteremia had not recurred nor was there any recurrence or difficulty with the initial lesion of the face. Roentgenograms of the thorax revealed a very small abscess in the upper lobe of the left lung. On this second admission the temperature was never higher than 98.6 F. Nevertheless, a second course of the calcium salt of penicillin was administered by the intravenous drip method. The patient received 80,000 units per day for seven days (total 560,000 units) and recovered.

The possibility of development of a delayed questionable metastatic lesion may argue in favor of higher doses. On the other hand, it would be interesting to

know the incidence of delayed recurrence in the presence of systemic infections of this type when even larger doses had been administered as a routine.

Subacute Bacterial Endocarditis.—Early in the course of our studies, penicillin was used in 4 cases of subacute bacterial endocarditis. In 2 of these cases a nonhemolytic streptococcus was the organism isolated, and in the other 2 cases a micrococcus was isolated. In all 4 cases treatment resulted in failure. The blood cultures in 1 of these cases became negative and remained negative for several months, but the patient died of heart failure. It seems apparent that the usual doses of penicillin are ineffective against subacute bacterial endocarditis. Recent reports from elsewhere, however, indicate that in early cases encouraging results have been obtained when 200,000 units or more of penicillin is given daily.

Fig. 4—*a*, draining sinus of thumb associated with osteomyelitis of the interphalangeal joint, cultures positive for *Neisseria gonorrhoeae*. *b*, appearance of thumb after penicillin therapy. Sinus completely healed. No limitation of motion in joint.

Final evaluation of results in the treatment of subacute bacterial endocarditis will depend on further observations.

Severe Cellulitis Without Bacteremia.—Penicillin was used in 25 cases of severe cellulitis without bacteremia. *Streptococcus pyogenes* was the organism isolated in 13 cases. In 9 *Staphylococcus aureus* was the organism of infection. In 3 the infections were with mixed organisms, including anaerobic streptococci, green producing streptococci and Vincent's spirillum. The results were satisfactory in 22 of the 25 cases. Failures or doubtful results were obtained in 3.

Postoperative Wound Infection.—Penicillin has been used in the treatment of 8 very severe postoperative wound infections. In most instances the organism isolated from these wounds was *Streptococcus pyogenes* or *Staphylococcus aureus*. In 5 of these cases both organisms were present. The results were entirely satisfactory in 7 of the 8 cases.

Osteomyelitis.—Penicillin has been used alone or in combination with surgical measures in 22 cases of osteomyelitis. Since penicillin is active against most strains of *Staphylococcus aureus* as well as against the microaerophilic streptococci, it was reasonable to hope early in the course of studies on penicillin that it would prove effective in the treatment of osteomyelitis. Of the 22 cases of osteomyelitis, 11 were of the acute or subacute type. Of the 11, 9 were examples of spreading osteomyelitis of the maxillary or frontal bone, in which the organism isolated was the microaerophilic streptococcus. Penicillin, combined with surgical eradication of the diseased bone, yielded a satisfactory recovery in all 9 cases. There were 2 cases of acute fulminating osteomyelitis involving the long bones due to *Staphylococcus aureus*. Both patients recovered, although it was necessary to resort to surgical drainage in both cases. It may be possible that osteomyelitis of the flat bones responds more satisfactorily than osteomyelitis of the long bones.

In 11 cases of chronic osteomyelitis, penicillin has been used in treatment. The results are listed tentatively as doubtful in 10 and satisfactory in 1. Long observation must precede definite conclusions. In any event, it must be stated again that thorough surgical drainage and eradication of foci play important parts in the successful treatment of this disease.

Gas Gangrene.—Penicillin has been employed in treatment of 6 patients suffering with gas gangrene. Organisms predominantly present in these cases were *Clostridium welchii* and anaerobic streptococci. In 1 of the cases antitoxin was not used. In the remaining 5 cases antitoxin and, in some instances, surgical treatment were combined with penicillin. The results were satisfactory in 4, and failures occurred in 2 instances. We feel, as do the British investigators,¹⁷ that antitoxin must be combined with penicillin. While penicillin may definitely inhibit the growth of the organisms associated with gas gangrene, the neutralizing effect of antitoxin is essential.

Sulfonamide Resistant Gonorrhea.—Since the first report¹⁸ on experimental and clinical effectiveness of penicillin in sulfonamide resistant gonorrhea, penicillin has been found an exceedingly effective agent in treatment of this disease. Although we have treated a total of only 19 patients, all 19 have had satisfactory results. Two of these patients were suffering with gonorrheal arthritis in addition to sulfonamide resistant urethritis. The symptomatic response of the arthritis was striking. The arthritis was cured in both cases without instillation of penicillin into the joint. In 1 instance the arthritis involved the knee and in the other case the interphalangeal joint of the thumb. In this instance a draining sinus was present and cultures from this sinus revealed *Neisseria gonorrhoeae*. Roentgenograms revealed suppurative arthritis, with osteomyelitis. Without surgical intervention, complete healing resulted and roentgenograms after treatment were negative. This lesion, before and after treatment, is represented in figure 4 *a* and *b*. It is rarely necessary to use more than 100,000 to 150,000 units of penicillin as a total dose in the treatment of uncomplicated genitourinary neisserian infections. It may be necessary to use more in certain cases in which the condition is complicated by arthritis, endocarditis and so forth.

18. Herrell, W. E.; Cook, E. N., and Thompson, Luther. Use of Penicillin in Sulfonamide Resistant Gonorrheal Infections, *J. A. M. A.* 122: 289-292 (May 29) 1943.

Actinomycosis.—Twelve patients with maxillofacial, thoracic or abdominal actinomycosis have been treated with penicillin. In 2 cases the treatment is listed as having failed and in 2 as having given satisfactory results. The remaining 8 of the 12 patients have not been followed long enough to justify final statements as to the outcome, and for that reason results in these 8 cases are listed as doubtful. Before a final report on actinomycosis is submitted, it is planned to follow these patients for at least eighteen months. At that time a detailed report on sensitivity of the organism, methods of treatment and results will be made.

Infections of the Urinary Tract—Infections of the urinary tract due to susceptible organisms, such as *Staphylococcus aureus*, respond satisfactorily to penicillin. Seven patients have been treated. In 4 cases the result can be considered entirely satisfactory. In 3 the result was doubtful or failure resulted because of the ineffectiveness of penicillin against gram-negative organisms such as *Proteus*, *Pyocyanus* and *Escherichia coli*.

Meningitis.—Penicillin was used in treatment of 4 patients suffering with meningitis. Two of these cases were examples of meningitis due to *Neisseria intracellularis*, in 1 of which there was an accompanying bacteremia and in 1 of which there was not. The patient suffering with meningitis and bacteremia recovered; the other died. The infection of both patients had resisted sulfonamide therapy. Of the 2 other cases in which penicillin was used, 1 was an example of meningitis due to an anaerobic streptococcus. In this case the spinal fluid became negative under penicillin therapy and it appeared that the meningitis had responded satisfactorily. On the other hand, the patient died of an abscess of a frontal lobe of the brain. The fourth patient suffered with overwhelming meningitis due to staphylococci; the patient died. All these patients received, in addition to intravenous or intramuscular therapy, daily intrathecal injections of penicillin in the amounts outlined in the paragraph on intrathecal instillation.

Pulmonary Suppurative Disease—Penicillin was used in the treatment of 6 patients suffering with pulmonary suppurative disease. Included in this group were pneumonia, pulmonary abscess and empyema. The results were satisfactory in 5 of the 6 cases. Failure occurred in the treatment of a man aged 66 who was suffering from extensive bilateral postoperative pneumonia due to *Diplococcus pneumoniae*, type III. In spite of intensive penicillin therapy, the patient died.

Miscellaneous Diseases.—Listed under miscellaneous diseases are 10 cases, in 6 of which satisfactory results were obtained. Of the 6 patients who obtained satisfactory results 4 had suppurative disease of the middle ear or mastoid process. Infection in all 4 had resisted sulfonamide therapy and all recovered. The organism isolated in 3 of the 4 cases was *Staphylococcus aureus* and, in 1, *Streptococcus pyogenes* was the infecting organism. Of the other 2 of the 6 cases in which the results were satisfactory 1 was an example of extensive ophthalmitis and conjunctivitis due to *Neisseria intracellularis*. In the other the organism isolated from the throat was *Corynebacterium diphtheriae*.

The 4 cases in the miscellaneous group in which failure occurred included 1 case of bilateral otitis media in which the infection was complicated by severe enteritis; the patient was an infant and the causative organism was the *Staphylococcus aureus*. One case represented

severe brucellosis with brucella bacterial endocarditis. In 1 case acute leukemia was accompanied by secondary infection of the jaw, and the fourth failure occurred in a case in which penicillin was tried against induced malaria due to *Plasmodium vivax*. The results in the entire series are listed in table 3.

Comment on the Analysis of Cases.—It is evident from examination of the clinical results just reported that penicillin is an effective agent in treatment of practically all of the staphylococcal infections, whether or not bacteremia is present, with the possible exception of chronic osteomyelitis. These infections include extensive cellulitis, meningitis, pulmonary suppurative disease, suppurative disease of the kidney and infected wounds. Penicillin is equally effective against hemolytic streptococcus infections with or without bacteremia. It appears to be effective in the treatment of gas gangrene and anaerobic streptococcus infections. It is effective against sulfonamide resistant infections with *Diplococcus pneumoniae* and against all of the sulfonamide resistant gonorrheal infections, including complications commonly encountered in this disease.

* 151 diagnoses because of 1 patient who had both bacteremia and meningitis.

Further observation will be necessary; however, penicillin appears to be promising in the treatment of certain types of infections due to *Actinomyces bovis*. One of the most interesting observations in connection with studies on penicillin is that which concerns its anti-spirochetal action, first reported by Mahoney, Arnold and Harris.¹⁹ Since the report by Mahoney and his associates,¹⁹ F. R. Heilman and one of us²⁰ have found penicillin to be effective against other spirochetal infections, including relapsing fever and Weil's disease. Our experimental studies on relapsing fever have received confirmation in the reports by Lourie and Collier²¹ and by Augustine, Weinman and McAllister.²² It would appear from the studies of Lourie and Collier and from the studies reported by Heilman and one of us²³ that penicillin is also effective against *Spirillum minus*, one

of the etiologic organisms of rat bite fever. Clinical studies have not as yet been reported on the spirochetal diseases which we have studied in experimental animals. Evidence is accumulating that penicillin has a definite place in syphilotherapy.

CONTRAINDICATIONS TO PENICILLIN THERAPY

On the basis of present knowledge, use of penicillin should not be attempted in treatment of gram-negative bacillary infections such as undulant fever, tularemia or influenza, or in the treatment of infections due to the colon-typhoid-dysentery group of organisms or to Friedländer's bacillus. Infections of the urinary tract due to the gram-negative organisms mentioned do not respond to penicillin therapy. At present it appears that penicillin should not be employed in the treatment of tuberculosis, acute rheumatic fever, lupus erythematosus, pemphigus, mononucleosis, leukemia, ulcerative colitis, malaria, blastomycosis and certain virus infections. On the other hand, the experimental work of F. R. Heilman and one of us²⁴ strongly suggests that penicillin may prove of value in the treatment of at least two virus infections in man; namely, ornithosis and psittacosis.

REACTIONS

Clinical experience with penicillin indicates that its use is not attended by many serious toxic reactions. There has been no evidence of disturbance in the peripheral blood or in the hemopoietic system. On the contrary, penicillin can be successfully used in the presence of pronounced anemia or pronounced leukopenia or even complete agranulocytosis. We have repeatedly seen suppressed leukocyte counts rise during the course of penicillin therapy in the face of overwhelming infection associated with suppression of the bone marrow. No evidence of renal toxicity has been seen.

The local irritation at the site of intramuscular and intravenous injection of penicillin already has been dealt with.

As long as pyrogen free penicillin is used, febrile reactions are not likely to occur. Cutaneous sensitivity to penicillin itself, or perhaps to impurities in the preparations, has been observed in only 2 of 150 cases. In both instances the reaction occurred when penicillin from one commercial source was being administered. When urticaria or dermatitis develops as the result of sensitivity to penicillin, great caution must be used in continuing to administer the material. Persistence of treatment in the face of a generalized cutaneous reaction might lead to development of exfoliative dermatitis. The skin of many persons is known to be sensitive to various molds and mold products. This cutaneous toxic reaction may become of more significance as penicillin is more generally used.

SUMMARY AND CONCLUSIONS

Penicillin therapy should be confined to infections due to pathogens known to be susceptible to its action.

Serious toxic reactions have not followed use of either the sodium or the calcium salt for intrathoracic, intra-articular or intrathecal instillation; nor have such reactions attended local application or intramuscular or intravenous administration in the doses recommended.

Local irritation at the site of injection of either the sodium or the calcium salt of penicillin varies with different batches. Changing the site of administration or changing the product often will terminate this reac-

tion. The only other toxic reaction of any significance is the occurrence of urticaria and irritative dermatitis. The latter reaction is very infrequently seen. Febrile reactions may occur if the penicillin employed is not pyrogen free.

The continuous intravenous drip method of administration of penicillin best maintains a constant level in the blood.

While penicillin diffuses fairly readily into most tissues, it does not reach the spinal fluid following intravenous or intramuscular injection. It is necessary, therefore, to administer penicillin by the intrathecal route at least once daily in treatment of infections involving the cerebrospinal structures. Following intravenous administration of penicillin, antibacterial amounts of the material reach the fluid of septic joints. Likewise, penicillin is transmitted through the placenta from the mother to the fetus. This is important in penicillin therapy for antepartum syphilis.

We believe Fleming's adaptation of the Wright slide cell technic to be the most reliable method of determining the penicillin content of serum.

Of 150 patients suffering with infections owing to a variety of pathogenic bacteria, 103 were treated with the sodium salt of penicillin and 47 with the calcium salt. The calcium salt is handled more easily and appears more stable. Among 28 patients suffering with bacteremia, most of whom had resisted sulfonamide therapy, 25 recovered and 3 died. At present, 80,000 units in twenty-four hours appears to be the most satisfactory dose in cases of bacteremia.

Other bacterial infections for which we have used penicillin include bacterial endocarditis, severe cellulitis, postoperative wound infection, osteomyelitis (acute and chronic), gas gangrene, sulfonamide resistant gonorrhea, actinomycosis, infections of the urinary tract, meningitis, pulmonary suppurative disease and a small group of miscellaneous infections. The results with 107 patients (1 of whom was counted twice, as is explained in table 3) could be considered brilliant or satisfactory; doubtful results or failures occurred with 44.

The use of penicillin should not be attempted in the treatment of gram-negative bacillary infections, including undulant fever, tularemia, influenza, infections due to the colon-typhoid-dysentery group or infections due to *Klebsiella pneumoniae*. Infections of the urinary tract due to gram-negative organisms do not respond to penicillin. It has not proved useful in treatment of tuberculosis, acute rheumatic fever, lupus erythematosus, pemphigus, mononucleosis, leukemia, ulcerative colitis, malaria or blastomycosis.

ABSTRACT OF DISCUSSION

DR. WALTER S. PRIEST, Chicago: I concur that the constant intravenous drip is the method of choice whenever feasible. It is possible to give the intravenous drip as slowly as 8 to 12 drops per minute continuously over periods of days without removing the needle, and that enables one to keep down the fluid intake where that is necessary. I have not been as fortunate as Dr. Herrell in regard to venous irritation, but I find, as he does, that it is not significant and that permanent thrombophlebitis has been a rarity. The reaction subsides promptly. Regarding the intramuscular administration, I have had one experience in which the patient had less irritation by using a more concentrated solution, up to 15 or 16 thousand units per cubic centimeter instead of the more usual 5 thousand. Dr. Herrell's comments on the use of 80 thousand units for twenty-four hours are noteworthy. Perhaps I have fallen into the habit of using larger doses unnecessarily. Since the present ampules are p-1

24. Heilman, F. R., and Herrell, W. E.: Penicillin in the Treatment of Experimental Ornithosis, *Proc. Staff Meet., Mayo Clin.* 19:57-65 (Feb. 9) 1944; Penicillin in the Treatment of Experimental Psittacosis, *ibid.* 19:204-207 (April 19) 1944.

up with a hundred thousand units per cubic centimeter it may be more practical to start with that as the initial twenty-four hour dose, by whatever method given, giving a somewhat larger dose at first and then adjusting the dose up or down as the patient's reaction seems to warrant. Certainly the smallest dose necessary to get the result is the one which should be used. During the past year I have had an opportunity to study the use of penicillin in large doses in 8 cases of subacute bacterial endocarditis. The infective organisms were of the viridans group, the hemolytic streptococcus group and the nonhemolytic nonrenal recrudescant streptococci. These patients received from 100 thousand to 400 thousand units of penicillin in twenty-four hours by the continuous intravenous drip method over a period of not less than four weeks. Out of this group, 2 are apparently cured, 1 is fever and bacteria free but still with an elevated sedimentation rate, 2 appear to be frank failures but are still alive, and 3 have died during the course of treatment. Has Dr. Herrell had any experience in the treatment of bronchiectasis with penicillin?

DR. K. R. BROWN, Des Moines, Iowa: I want to know whether Dr. Herrell finds penicillin effective in cavernous sinus thrombosis complications from facial cellulitis.

DR. WINGATE M. JOHNSON, Winston-Salem, N. C.: Dr. Herrell gave an exhaustive list of diseases in which penicillin is indicated and in which it is not. I don't believe he mentioned one important group, the rickettsial diseases.

DR. WALLACE E. HERRELL, Rochester, Minn.: The point which Dr. Priest raised as to whether or not higher concentrations might have prevented the three failures in the cases of bacteremia deserves consideration. We find that administration of 80 thousand units in twenty-four hours results in a concentration of penicillin which is adequate to inhibit the organisms. Since most of the penicillin is dispensed in ampules of 100 thousand units I am inclined to agree that in general practice it would probably be worth while to use the contents of the 100 thousand unit ampule in preparing the twenty-four hour dose. Excluding bacterial endocarditis, however, we still do not feel that 200 to 300 thousand units per day is necessary to obtain satisfactory results in cases of bacteremia when the agent is administered by the intravenous drip method. The penicillin content of the blood of a patient receiving around 80 thousand units per day will usually be found to be somewhere around 0.06 to 0.12 Oxford unit per cubic centimeter, which is adequate to cause complete inhibition and keep the blood sterilized. In the 3 individuals who failed to recover, necropsy revealed acute ulcerative endocarditis. All 3 had heart murmurs and other clinical signs suggestive of endocarditis at the time penicillin therapy was started. When endocarditis is present at the time one begins penicillin therapy, the results usually will not be satisfactory even when very large amounts of penicillin are administered; at least this has been our experience. Better results will be obtained in the treatment of patients with bacteremia when it is no longer necessary to defer penicillin therapy until sulfonamides have been tried and have failed. I am sure Dr. Priest feels that it is too early to evaluate these results completely, but it is well worth while to continue to treat these patients so long as the organism present in their blood is found to be sensitive to penicillin. Many of the organisms present in subacute bacterial endocarditis are not sensitive. Dr. Priest's remarks concerning the febrile reactions incident to intravenous therapy are extremely important. Old tubing and apparatus not carefully prepared will result in febrile reactions which are not truly due to the penicillin. One must use the same precautions that he would in any intravenous medication. The same precautions must also be rigidly observed when penicillin is given intramuscularly, to avoid the introduction of bacteria or foreign substances which might lead to the development of localized abscesses. It is well known that patients receiving penicillin intramuscularly eight times a day are liable to get "needle shy." We have not had any experience in the treatment of bronchiectasis per se, although we have used penicillin therapy with encouraging results in preparation for lobectomy and in post-operative treatment. Concerning sinus thrombosis, it is safe to say that penicillin has resulted in a cure in many cases. I feel certain that 1 of our patients suffering from staphylococcal bacteremia had a sinus thrombosis and that he recovered as a

result of penicillin therapy. This particular patient never regained vision in one eye. Concerning the effectiveness of penicillin against rickettsial infections, I might call attention to the experimental work reported by Pinkerton and his associates of St. Louis, which indicates that penicillin may prove effective against experimental typhus. Enough data have not yet been accumulated to warrant any statements concerning the clinical use of penicillin in virus infections. A virus may be quite susceptible to the action of penicillin and one may still not obtain a satisfactory clinical result, especially if the virus has become well fixed in the cells by the time one gets an opportunity to treat the patient.

PENICILLIN IN THE TREATMENT OF MENINGITIS

LIEUTENANT COMMANDER DAVID H. ROSENBERG
(MC), U.S.N.R.

AND

LIEUTENANT P. A. ARLING (MC), U.S.N.R.
GREAT LAKES, ILL.

Reports in the literature pertaining to the clinical effects of penicillin in the treatment of meningitis have in general been confined to observations on small groups of patients or on isolated cases.¹ No definite conclusions may be drawn from them concerning the efficacy of penicillin, the most satisfactory method of treatment or the minimum adequate dosage requirements. However, from in vitro studies demonstrating the pronounced sensitivity of the meningococcus, *Streptococcus haemolyticus*, pneumococcus and some strains of *Streptococcus viridans* to the action of penicillin, this agent should prove to be of considerable therapeutic value in the management of such infections, particularly in individuals who are sulfonamide resistant or sulfonamide reactors.

In a preliminary report² on 31 patients with cerebrospinal fever, we recorded 30 recoveries following the combined intrathecal and intravenous or intramuscular use of penicillin and concluded that penicillin is a safe, effective and highly potent agent in the treatment of this disease. Since then we have treated 40 additional patients with meningitis without a fatality. We are presenting at this time a report of our observations on this entire group of 71 patients.

MATERIAL

Cerebrospinal Fever.—Sixty-five patients in this series presented clinical evidence of cerebrospinal fever (table 1). In almost all patients the onset was sudden, with rapidly developing headache, nausea, vomiting and cervical rigidity of eight to forty-eight hours' duration. Twenty-four patients were semicomatose and 21 were comatose. The temperature on admission ranged between 99 (rectal) and 108 F. (rectal); the average for the group was 102.7 F. (rectal). Petechiae were found in 48 instances, and in 4 of these a purpuric rash was also noted. One patient with most extensive

purpura presented the clinical picture of the so-called Waterhouse-Friderichsen syndrome. Two other patients who went into shock shortly after admission exhibited widespread petechial eruptions without purpura. Acute arthritis was observed in 15 of the patients on admission. The spinal fluid was turbid in all except 4 patients, and the initial spinal fluid cell count ranged from 21 to 50,100 leukocytes per cubic millimeter. The average

Owing to a lack of serums we were unable to determine the type of meningococci isolated from this group of patients. In 15 patients the clinical picture and spinal fluid findings were characteristic of meningococcal meningitis, but the stained smears and cultures of the spinal fluid revealed no organisms.

Meningitis Due to Other Bacteria.—In 3 patients hemolytic streptococci were recovered from the spinal

* Cell count inaccurate owing to pellicle formation. In all cases the temperature was taken rectally. All patients were males.

cell count for the group was 11,700 per cubic millimeter, 88 per cent being polymorphonuclear leukocytes. In 49 patients meningococci were recovered from the spinal fluid, and in 10 of these the blood cultures were positive. In another patient with clinical evidence of fulminating meningococcemia the blood culture was positive although the spinal fluid was sterile and contained only 66 leukocytes per cubic millimeter. In the 3 other patients with clear spinal fluid on admission, meningococci were found in the spinal fluid on culture.

fluid (table 2). In one of these a bacteremia was present, and in another bilateral acute otitis media was found. Two of these patients were semicomatose on admission. The spinal fluid cell counts ranged between 1,000 and 2,290 leukocytes per cubic millimeter.

There were 2 patients with *Streptococcus viridans* bacteremia and meningitis, both of whom were comatose on admission. Although the initial spinal fluid cell count was 450 leukocytes per cubic millimeter in each instance, in 1 it rose to 25,600 within ten hours.

In 1 patient with acute otitis media complicated by meningitis, pneumococci were cultivated from the spinal fluid. This patient was semicomatose on admission and the maximum temperature was 105.2 F. (rectal). The initial spinal fluid cell count was 1,100 leukocytes per cubic millimeter.

METHOD OF TREATMENT

Rammelkamp and Keefer³ have demonstrated that penicillin administered intravenously does not appear in the spinal fluid. Injected intrathecally,⁴ penicillin is slowly absorbed from the subarachnoid space and may be detected in the spinal fluid thirty-one hours later. It is more rapidly absorbed from the spinal fluid of patients with meningitis but may be found in significant amounts twenty-four hours after injection.

For purposes of investigation our plan of treatment varied somewhat in different patients, particularly from the standpoint of dosage. The most satisfactory method of treatment was found to be the following:

1. The initial diagnostic lumbar puncture was performed in the usual manner⁵ and the spinal canal was

injecting penicillin. In several instances the spinal fluid was so viscous that aspiration was necessary.

2. Penicillin was also administered either by the continuous intravenous drip method at the rate of 5,000 units per hour or intramuscularly in doses of 15,000 units every three hours, the dose being reduced to 10,000 units every three hours if improvement was satisfactory. Generally, penicillin was given intravenously (40 units per cubic centimeter in a 5 per cent dextrose solution) for the first eight hours and continued intramuscularly thereafter. Patients with the fulminating type of cerebrospinal fever received penicillin intravenously at the rate of 10,000 units per hour for four hours initially. Owing to a lack of technical facilities the treatment could not be controlled by determinations of the amount of penicillin in the blood and spinal fluid. Instead, frequent clinical observations were made and the temperature, pulse and respirations were recorded every two hours.

In addition to specific therapy, 3,000 cc. of fluid was given daily. To combat shock in patients with fulminating meningococcemia, supportive therapy was

drained. Ten thousand Oxford units of sodium penicillin, dissolved in 10 cc. of isotonic solution of sodium chloride, was slowly introduced into the subarachnoid space. Penicillin (10,000 units) was administered intrathecally at twenty-four hour intervals until clinical improvement, sustained fall in temperature and/or a decrease in the meningeal signs were manifest and until the stained smears and cultures of the spinal fluid revealed no organisms. As penicillin was injected intrathecally with each lumbar puncture without awaiting the results of the bacteriologic studies, this plan in effect was tantamount to administering an additional dose of penicillin after the spinal fluid became sterile. We felt that in some instances it was unsafe to withhold treatment pending the results of the spinal fluid cultures. The persistence of coma was regarded as an indication for further intrathecal therapy. In the most severe infections and in those in which coma lasted forty-eight hours or longer, intrathecal penicillin was continued until the spinal fluid was bacteria free on three successive days. It is of paramount importance to drain the spinal canal as completely as is feasible before

given in the form of whole blood, plasma, epinephrine and desoxycorticosterone acetate. Oxygen therapy was employed when indicated.

RESULTS

Cerebrospinal Fever.—Sixty-four of the sixty-five patients in this group recovered. The one fatality occurred in a patient who was admitted in a moribund state with clinical and bacteriologic evidence of meningococcemia and with well advanced meningitis. His temperature was 108 F., pulse rate 140 and respiratory rate 66 per minute. He received 12 Gm. of sodium sulfadiazine parenterally in addition to 55,000 units of penicillin intrathecally and 380,000 units intravenously and intramuscularly but died thirty-eight hours after admission. Necropsy disclosed suppurative meningitis, secondary hydrocephalus and edema of the brain and lungs.

In the 64 patients who recovered, progressive improvement was noted soon after penicillin therapy was begun and was generally signalized by the disappearance of the restlessness, stupor and delirium, cessation of vomiting and an abrupt fall in the temperature and pulse rate. Those who were comatose usually regained consciousness within two to twenty-four hours, but in 5 coma persisted for thirty to forty-eight hours and in 1 for four days. In 22 patients the temperature returned to normal within eight to

seventy-two hours. In 16 a low grade intermittent fever (100 to 100.2 F. rectal) remained until the seventh day. In some of the latter patients as well as in those who exhibited a more prolonged febrile course the fever was found to be caused by one or more complications rather than by the meningitis, for the spinal fluid had become sterile and either gave a normal cell count or showed a residual lymphocytosis. Of the 4 patients whose temperature did not fall abruptly, 3 represented very severe infections and 1 showed signs of acute pericarditis and polyarthritis. Headache disappeared within two to four days and the signs of meningitis subsided completely in two to seven days (average, four days) except in our first 2 patients, who received 100,000 to 125,000 units intrathecally. In the latter the meningeal signs persisted for nine days. Generally there was a prompt reduction in the spinal fluid cell count, as shown in the accompanying chart, and the protein and sugar returned to normal rapidly. In all but the most severe infections this was accompanied by a disappearance of the polymorphonuclear leukocytes within four to seven days. In many a slight

Effect of penicillin on the temperature and spinal fluid cell counts of patients with cerebrospinal fever treated with 10,000, 20,000, 30,000, 40,000 and 50,000 units (total) intrathecally and various amounts intravenously and intramuscularly. Cases representing different grades of severity were selected. In patient S9, fever was prolonged by the presence of arthritis. The increase in the spinal fluid cell count in patients 16, 48 and 49 following the first injection of penicillin intrathecally was noted in 8 other patients. I. T., intrathecal, I. V., intravenous, I. M., intramuscular.

lymphocytosis remained until the tenth to the fourteenth day. In a few of our first patients a recurrence of fever was observed on the fourth to the sixth day if intrathecal penicillin was discontinued too soon. This was controlled by an additional dose of penicillin. As a rule the patients were able to be out of bed on the eighth day unless prevented by complications.

The amount of penicillin administered intrathecally to these patients varied with the severity of the meningeal infection. Thus, 42 patients recovered following only one or two injections of penicillin, 10 required three injections and 9 received four to five injections intrathecally. Through a lack of knowledge of the potency and effectiveness of penicillin, the first 2 patients whom we treated received nine and eleven injections respectively, totaling 100,000 to 125,000 units. Another patient with fulminating meningococcemia recovered with intravenous and intramuscular therapy alone, but in this instance the spinal fluid was

sterile and showed only 66 leukocytes per cubic millimeter. The first 8 patients whom we treated received an intrathecal dose of 15,000 units dissolved in 15 cc. of isotonic solution of sodium chloride initially, but in view of the symptoms and signs of meningeal irritation resulting therefrom the 10,000 unit dose was employed thereafter. It is noteworthy that the amount of intrathecal penicillin necessary for recovery cannot be correlated with the initial spinal fluid cell count. Instead, it seems to depend on the number, type and virulence of the organisms as well as on the immunologic reaction of the host.

An analysis of the bacteriologic effects of penicillin on the spinal fluid obtained twenty-four hours after an intrathecal injection discloses that of 48 patients with positive cultures on admission in 29 the spinal fluid was sterile after one injection of penicillin, in 8 after two injections, in 3 after three injections and in 4 after four injections. However, in 2 others, both with very severe infections, the spinal fluid was sterile after one injection of penicillin but again showed meningococci twenty-four hours after the second injection. In 1 of these the spinal fluid remained sterile after the third injection and in the other after the fifth injection. Further, in 2 patients receiving penicillin every twelve hours the spinal fluid cultures were sterile after the first injection of penicillin, yet the direct smears showed organisms until two and five injections, respectively, were given. These findings suggest that sufficient penicillin is present in the spinal fluid after twelve hours, and occasionally after twenty-four hours, to inhibit the growth of bacteria on the culture medium. It is important, therefore, to correlate the bacteriologic findings with the clinical course and to observe the criteria set forth in our plan of treatment.

The total amount of penicillin administered intravenously and/or intramuscularly varied considerably (20,000 to 900,000 units), the first patients treated receiving the largest amounts. We soon observed that the total dosage could be reduced considerably without risk to the patient. Thus, 55 patients received between 20,000 and 250,000 units of penicillin intravenously and intramuscularly, and 35 of these received 100,000 units or less. One patient, seen several hours after the onset of his illness, recovered without any penicillin intravenously or intramuscularly. Among the patients without bacteremia, no appreciable difference in the outcome and course of the disease was perceptible in the group treated with 20,000 to 50,000 units when compared with those receiving as much as 900,000 units. Nor was there any correlation between the amount of penicillin given by these routes and the amount of intrathecal penicillin required for recovery. Of 10 patients in whom positive blood cultures were found, in 4 the blood was sterile after 40,000 to 50,000 units, in 5 after 70,000 to 125,000 units and in 1 after 250,000 units. In 2 of these the blood was sterile after 105,000 to 110,000 units, but in each penicillin was continued until 200,000 units had been given. As 250,000 units was administered to the patient with the "Waterhouse-Friderichsen syndrome" this dose may represent the maximum amount required to combat the severe forms of meningococcemia unless circulatory failure is too far advanced when the patient is admitted to the hospital.

Acute monoarthritis or polyarthritis was present in 15 patients on admission and was uninfluenced by the intravenous and intramuscular administration of as much as 900,000 units of penicillin. In 9 individuals

aspiration of the affected knee joints revealed cloudy yellow fluid containing 20,000 to 100,000 polymorphonuclear leukocytes per cubic millimeter. In 8 the aspirated fluid was sterile, while, in the other, meningococci were found on direct smear and on culture. Intra-articular penicillin (10,000 units) was administered to 2 of the patients with sterile synovial fluid, but no beneficial effects were observed. In the patient from whose joint meningococci were recovered, the fluid became sterile after the intra-articular injection of 10,000 units of penicillin on two successive days.

Acute epididymitis, alone or with orchitis, developed in 10 patients. It usually appeared on the sixth to the seventh day of illness, although it was noted as early as the second day and as late as the tenth day. Its occurrence was unrelated to the amount of penicillin administered intravenously and intramuscularly. Three patients were treated with 150,000 to 160,000 units of penicillin over a period of forty-eight hours after the onset of acute epididymo-orchitis, but in none was the period of resolution shortened. In these as in the other 6 patients, spontaneous recovery ensued.

In 3 patients transient diplopia was observed without manifest cranial nerve involvement. Left sixth nerve palsy developed on the second day of admission in 3 of the most severe cases encountered in this series; in 1 of these it was followed twenty-four hours later by paresis of the right sixth nerve. In 2, restoration of function was ultimately complete; in the other, slight diplopia on extreme abduction remained. In 1 patient with fulminating meningococcemia slight transient third nerve paresis was noted. Acute fibrinous pericarditis was found on admission in 1 patient and was unaffected by 715,000 units of penicillin given intravenously and intramuscularly. In 4 patients acute tonsillitis and in another unilateral acute otitis media complicated the convalescence. In 2 instances acute thrombophlebitis of the saphenous vein developed on the fifth and sixteenth days, respectively, and was unrelated to the site of therapy.

Hemolytic Streptococcus Meningitis.—All 3 patients with meningitis due to hemolytic streptococci recovered completely following two intrathecal injections of penicillin. The spinal fluid was sterile twenty-four hours after the first injection, and the temperature returned to normal in four to six days. The patient with bacteremia was given 400,000 units intravenously and intramuscularly over a period of fifty-three hours. Blood drawn for culture on the fifth day was sterile. One of the patients without bacteremia received only 170,000 units of penicillin intravenously and intramuscularly over a period of thirty-nine hours. The temperature returned to normal within six days. The other patient with meningitis secondary to bilateral acute otitis media was given 650,000 units of penicillin intramuscularly over a period of eight and one-half days, although the temperature was normal in five days. No surgical intervention was necessary in this instance.

Streptococcus Viridans Meningitis.—Both patients recovered from meningitis, one following three and the other after four intrathecal injections of penicillin. The blood cultures were sterile in 1 patient after 40,000 units intravenously and in the other after 130,000 units intravenously and intramuscularly. However, penicillin was continued until 200,000 and 300,000 units, respectively, had been administered over periods of three to four days. The temperature returned to normal after

three to five days. No sequelae were demonstrable, though both patients were comatose for twenty-four hours after therapy was begun.

Pneumococcal Meningitis Secondary to Acute Otitis Media.—Although there was only 1 patient with pneumococcal meningitis in our series, it is of interest that complete recovery followed three intrathecal injections of penicillin and 800,000 units given intravenously and intramuscularly over a period of ten and one-half days. The spinal fluid cultures remained positive until the third intraspinal injection of penicillin was administered. In view of the presence of acute otitis media and the possibility of bony suppuration in the areas adjacent to the middle ear, intramuscular penicillin was continued until the temperature remained normal for five days. Convalescence progressed uneventfully thereafter without surgical intervention.

UNTOWARD EFFECTS

In those patients who received penicillin intrathecally every twelve hours, as well as in some individuals who were given intrathecal doses of 15,000 units, more severe and more persistent headache was noted, fever was prolonged and signs of meningitis subsided more slowly. The irritating effect of penicillin on the meninges, when injected intrathecally, was previously demonstrated by Rammelkamp and Keefer⁴ and by Pilcher and Meacham.⁵ Further, we observed that penicillin produced by different manufacturers caused various degrees of meningeal irritation. Thus, the dark brown product was found to have the greatest irritant effect and caused febrile reactions, whereas the pale yellow product had the least demonstrable irritant effect. It is our belief, therefore, that the dark brown powder should not be used intrathecally. Localized thrombophlebitis developed in 4 patients at the site of the continuous intravenous injections but was of minor significance. In 3 patients with cerebrospinal fever mild transitory urticaria was noted within twenty-four hours after therapy was started. Whether this should be ascribed to the penicillin or to the disease per se cannot be stated. No other local or toxic effects were observed.

COMMENT

The effectiveness of penicillin in the treatment of meningococcal infections in man is clearly demonstrated by the recovery of 64 out of 65 patients with cerebrospinal fever. That penicillin is also a potent agent in the control of meningitis caused by *Streptococcus haemolyticus*, *Streptococcus viridans* and *pneumococcus* is indicated by the recoveries observed in our small series of 6 patients. Contrary to the reported experiences with other infections, relatively small amounts of intravenous and/or intramuscular penicillin (40,000 to 250,000 units) were required to sterilize the blood stream in our cases of meningococcemia. Further, it was not necessary to continue penicillin for long periods of time, eight to forty-eight hours of therapy being adequate for these patients. It seems logical to assume that, when combined with intrathecal therapy, these data are equally applicable to the treatment of the nonbacteremic cases, the larger doses being employed in the more serious types of infection. On the other hand, in meningitis secondary to otitis media, intravenous or intramuscular penicillin must be continued until all other sources of infection have been adequately controlled. The majority of patients with cerebrospinal

5. Pilcher, C., and Meacham, W. F.: The Chemotherapy of Intracranial Infections: III. The Treatment of Experimental Staphylococcal Meningitis with Intrathecal Administration of Penicillin, *J. A. M. A.* 123: 330 (Oct. 9) 1943.

fever received only one or two injections of penicillin intrathecally, whereas in the most severe infections as much as five injections were necessary for recovery. It would appear safer, however, to administer a minimum of two intrathecal injections of 10,000 units each to all patients, even though many of the milder or earlier infections may be controlled by a single injection. As 2 patients without bacteremia recovered following only 20,000 units intravenously and 10,000 units intrathecally, and another recovered with intrathecal therapy alone, the question may be raised whether any intravenous or intramuscular penicillin is indicated in the nonbacteremic cases. Since the clinical picture presented by patients with bacteremia is often indistinguishable from that observed in individuals with negative blood cultures, it is our belief that penicillin should be administered intravenously or intramuscularly to all patients with meningitis. Moreover, it is of the utmost importance to continue penicillin intrathecally until recovery is assured, observing the criteria outlined in our plan of treatment. The findings of Pilcher and Meacham⁵ in experimental meningitis support the latter contention.

The failure of penicillin to alter the course of arthritis or pericarditis was not unexpected. Similar failures have been observed with sulfonamide therapy.⁶ It is probable that neither of these agents is excreted into these spaces in sufficient amounts, if any, to be effective. The occurrence of epididymitis, with or without orchitis, in 10 patients with cerebrospinal fever is of interest, as it is generally regarded as rare. However, it has been found quite frequently in some epidemics⁷ and has also been observed following sulfonamide therapy.

We are fully cognizant of the shortcomings of any therapeutic agent requiring intrathecal administration to achieve its maximum effectiveness. Notwithstanding, it is evident from our experiences that for those patients who develop reactions to the sulfonamides, or in whom sulfonamide therapy is contraindicated for other reasons, for those who are sulfonamide resistant and for those with the fulminating bacteremias wherein a highly potent agent is indicated, penicillin alone may prove life saving. It is not unlikely that, when ultimately prepared in a more concentrated and more highly purified form, free from pyrogens, penicillin may be excreted into the subarachnoid spaces in sufficient amounts following intravenous or intramuscular administration to justify the abandonment of intrathecal therapy. Until then, penicillin should be administered intrathecally as well as intravenously or intramuscularly in the treatment of meningitis.

SUMMARY AND CONCLUSIONS

1. Penicillin was administered intrathecally and intravenously or intramuscularly to 65 patients with cerebrospinal fever (11 with bacteremia), 3 patients with hemolytic streptococcus meningitis (1 with bacteremia and 1 with acute otitis media), 2 patients with streptococcus viridans bacteremia and meningitis and 1 patient with pneumococcal meningitis secondary to acute otitis media. Seventy of the 71 patients recovered. Except for slight unilateral paresis of the sixth cranial nerve in 1 patient, no sequelae were observed.

2. Although one intrathecal injection of 10,000 units controlled some of the milder or earlier infections, a

minimum of two injections is advocated as a precautionary measure. In the severe infections as much as five intrathecal injections (50,000 units) were required. Bacteremia was controlled by 40,000 to 130,000 units of penicillin intravenously and intramuscularly in the majority of instances. In a patient with fulminating meningococcemia and "Waterhouse-Friderichsen syndrome," 250,000 units over a period of forty-eight hours was followed by recovery. In meningitis secondary to otitis media more prolonged intravenous or intramuscular therapy is indicated.

3. Intravenous and intramuscular penicillin is ineffective in the treatment of such complications of meningococcemia as acute arthritis, epididymitis, orchitis or pericarditis.

4. Penicillin administered both intrathecally and intravenously or intramuscularly is an effective, highly potent agent in the treatment of meningitis. No significant untoward effects are demonstrable.

ADDENDUM.—Since the preparation of this paper penicillin was administered to 11 other patients with cerebrospinal fever. All of them recovered. For 12 patients who had manifested symptoms of meningitis for one week prior to hospitalization, six intrathecal injections of penicillin (60,000 units) were required.

ABSTRACT OF DISCUSSION

DR. WALLACE E. HERRELL, Rochester, Minn.: In view of the sensitivity of *Neisseria intracellularis* to penicillin, it is not surprising that such satisfactory results have been obtained. In 90 per cent of certain cases recovery will follow the use of sulfadiazine or one of the other sulfonamides. Penicillin, however, is an agent which appears relatively free of any serious toxic reactions. When greater supplies of penicillin are available it seems likely that it may be possible, as well as desirable, to treat all of these patients with penicillin without waiting for failures to occur with sulfonamides. This might well result in even greater success than has been attained in the past. It is my opinion that meningitis due to the several organisms isolated in 6 of the 71 cases reported by the authors will be found to respond in a less satisfactory manner to penicillin. It is the experience at the present time that probably no better recovery rates than 60 per cent have been experienced with penicillin. The plan of treatment which has been outlined is an exceedingly satisfactory one. In addition to being administered by the intrathecal route, penicillin also should be given intramuscularly or intravenously in cases of meningitis. It is interesting that Rosenberg and Arling have found that relatively small amounts of penicillin (250,000 units) have been satisfactory. In meningitis due to pneumococci or streptococci I believe that larger amounts of penicillin will be required for the total dose and that the course of treatment will necessarily be somewhat longer. In connection with the arthritis complicating meningococcal meningitis, it is at times difficult to isolate the organism from the joint fluid. Nevertheless I am inclined to believe that there was definitely some beneficial effect. A positive culture was obtained in only 1 of 9 cases of septic arthritis in which cultures were made. Using Fleming's modification of the Wright slide cell technic, my associates and I have made determinations of the concentration of penicillin in the joint fluid of patients receiving this agent. In many instances we have found satisfactory antibacterial amounts of penicillin in the joints. The ratio of blood to joint fluid content is approximately 2 to 1. Urticaria or irritative dermatitis has been observed by us in 2 of 150 cases. I believe this skin reaction will be observed more frequently as more and more penicillin is used. Many people are sensitive to molds and to mold products. One must exercise caution in the presence of irritative dermatitis or severe urticaria. Continuing to force penicillin might result in the development of an exfoliative dermatitis, although at times one may administer penicillin without difficulty to patients who have previously exhibited this reaction.

LIEUTENANT COMMANDER DAVID H. ROSENBERG (MC), U.S.N.R.: Dr. Herrell's comments regarding arthritis are of interest. Our observations were based on the duration of the symptoms and signs of arthritis. It is apparent that the effects of penicillin in these complications should also be studied by assays of the penicillin content of the affected joints.

PENICILLIN AND SKIN GRAFTING

Few patients are more miserable than those with large unhealed third degree burns. Early skin grafting of the burned areas is the only means of quickly returning these patients to a useful life. The longer this procedure is delayed, the greater the immediate threat of death and the ultimate development of scars and deformity. The aim of all treatment, therefore, is reepithelization of the burned areas as promptly as possible. In general, it requires from one to three months to achieve this aim. The chief causes for the prolonged healing are (1) the necessity of deferring grafting until the burned tissue has sloughed and the granulating bed is ready to accept a graft, (2) the necessity for multiple grafting operations because of the lack of sufficient donor sites or the inability of the patient to tolerate grafting of the entire burn at one time and (3) the necessity of grafting the same area more than once because previous grafts have partially or completely failed to take.

Harvey and Connor¹ have devised a method of rapidly removing the dead tissue. Ordinarily it requires fifteen to forty days for burned tissue to separate. By shortening this time to a few days they have overcome one of the greatest factors prolonging the convalescence of burned patients. Although lack of donor sites will always remain as a limiting factor, improvements in the care of burned patients have made it possible and will continue to make it possible to graft larger areas at one operation. The necessity of grafting the same area more than once remains, therefore, as the chief factor tending to prolong the convalescence of these patients.

Skin grafts fail to take because of (1) infection, (2) failure to maintain the graft in contact with the recipient site and (3) the lack of adequate blood supply in the recipient site. Any one skilled in the art of skin grafting has at his command the means of maintaining a skin graft in contact with the recipient site and of insuring an adequate blood supply for the graft. However, in spite of the most careful preparation of the granulating bed a certain number of split thickness grafts are partially or completely lost because of infection.

Padgett² reported the percentage of takes of a large series of split thickness grafts applied to contaminated and to aseptic recipient sites. The analysis of his

results (table 1) shows that infection is the most common cause of partial or complete loss of such a graft.

In approximately one third of the cases in which grafts were placed on contaminated recipient sites, 25 per cent or more of the graft was lost. In only about two thirds of these patients were satisfactory takes obtained in which only 10 per cent or less of the graft was lost. In contrast, satisfactory takes were obtained in 98 per cent of the grafts done on aseptic recipient sites. Furthermore, a review shows that many patients whose first grafts failed also lost large parts of successive grafts. This has been our experience and has usually been due to infection of the granulating bed with sulfonamide resistant *Streptococcus haemolyticus* or *Staphylococcus aureus*.

A large denuded area of the body usually becomes infected with *Pseudomonas pyocyaneus*, *Proteus vulgaris*, *Escherichia coli* or other gram negative bacilli of intestinal origin. There is yet no chemotherapeutic agent that will adequately control these organisms. Fortunately, in most cases they seem to act primarily as saprophytes and do not interfere with the growth of split thickness grafts. Many burns, however, become

infected with beta hemolytic streptococci, *Staphylococcus aureus* and other coagulase positive micrococci. It is these organisms that are responsible for the failure of skin to grow when transplanted to granulating surfaces. Although the sulfonamides control many hemolytic streptococcus infections, they are ineffective against the occasional resistant strain and against *Staphylococcus aureus* and the other coagulase positive micrococci. While their use has improved the results of skin grafting, especially in the presence of susceptible hemolytic streptococci, it has not solved the problem.

Penicillin is an extremely powerful bacteriostatic and bactericidal agent that has the advantage of acting not only against *Streptococcus haemolyticus* but also against *Staphylococcus aureus*. It seemed important, therefore, to determine whether its administration at the time of skin grafting would improve the percentage of takes.

Nineteen split thickness grafts were performed on 17 patients who were receiving penicillin intramuscularly. In general, grafting was done as soon as the slough had separated, usually three to four weeks after the burn had occurred. In 5 instances, however, grafting was delayed because of (1) the slow separation of a deep slough, (2) the necessity for multiple operations or (3) the admission of patients to our hospital some time after they had been burned. The initial dressings consisted of a wide variety of substances, zinc oxide ointment, glass cloth and cellucotton, zinc

peroxide in a carbowax base, and several other experimental ointments. The dressings were changed at intervals of five to fourteen days, depending on the patient's condition and the requirements of certain studies that were in progress on these patients. In only 2 instances were wet dressings employed. At the time of grafting the dressings were removed in the operating room, and the exudate was washed away with warm isotonic solution of sodium chloride. If the granulations were excessive they were cut away; otherwise the grafts, which were cut with the Padgett dermatome, were placed directly on the granulating bed and held in place with fine silk sutures. A single layer of fine mesh gauze impregnated with zinc oxide ointment was placed next to the graft. This was covered with a few layers of ordinary gauze, and the entire area was then covered with mechanics' waste and wrapped with elastic bandage. The initial dressing was changed on the fourth, fifth or sixth day.

All the patients received penicillin intramuscularly. The dose and the duration of therapy varied somewhat from patient to patient. In general, therapy was started about twelve hours before operation and was continued until the time of the first dressing. The exact details of therapy are given in table 2. With one exception, from 90 to 100 per cent of the transplanted skin took in every instance. The exception occurred in an uncooperative alcoholic addict who had third degree burns of the perineum, both thighs and legs. Only 80 per cent of the grafts placed on his groin and thighs took. The loss in this case was probably due to failure of the dressings to hold the grafts in place.

The loss in all cases occurred at the margin of the grafts where they overlapped the new epithelium growing in from the margins of the burned area. This thin layer of new epithelium prevents the graft from taking, and, unlike normal skin, it is not strong enough to survive when covered with a graft. The result is a slough of both the new epithelium and the margin of the graft. If the new epithelium is cut away and the graft joined to normal skin, this marginal loss does not occur.

The administration of penicillin did not seem to alter the bacterial flora a great deal; cultures taken at the time of the first dressing from the margins of the grafts and from the sutures usually yielded the same organisms that were present on the granulating surface before grafting. In spite of their persistence, they did not seem to affect the growth of the graft. Penicillin, therefore, must hold them in check until the skin has a chance to become established in its new bed.

Though penicillin has been administered to only 17 patients at the time of skin grafting, we believe that its use has the following definite advantages:

1. It permits early grafting. Split thickness grafts can be successfully applied as soon as the slough has separated without further time consuming preparation of the granulating area.
2. It appears to prevent the loss of skin from infection that ordinarily occurs in about one third of the cases in which split thickness grafts are placed on contaminated recipient sites.

Before penicillin was available, we performed over a hundred grafts in patients with third degree burns. Although many excellent takes were obtained, in about one third of the cases 25 per cent or more of the graft was lost because of the occurrence of infection. Therefore the consistency with which excellent takes were obtained in this series of 19 grafts has been very impressive to us. We are presenting the method with the hope that others will try it.

TREATMENT OF OSTEOMYELITIS OF THE FACIAL BONES WITH PENICILLIN

WILLIAM M. M. KIRBY, M.D.

AND

VIRGIL E. HEPP, M.D.

SAN FRANCISCO

One of the most serious complications of sinusitis is osteomyelitis of the facial bones. This may occur either following surgical operation or by direct extension from the diseased sinuses. In either instance the outlook has always been very poor, for, in spite of sulfonamides and operative intervention, the infection tends to extend throughout the bone and to spread to the brain and meninges, with a mortality in severe cases of as high as 80 per cent. With penicillin, however, there was every reason to think that the prognosis might be greatly altered, for this powerful bacteriostatic agent might hold the infection in check until adequate surgery could be performed. The cases reported here, in which brilliant results were obtained, showed that such was the fact and are reported because they illustrate the technical problems both of penicillin administration and of surgical treatment.

CASE 1.—Development of cellulitis and osteomyelitis following intranasal maxillary antrotomy; no response to sulfonamides; prompt response to penicillin, with three relapses; complete cure after removal of all necrotic bone.

Mrs. M. W., a woman aged 32, housewife, who entered Stanford Hospital on Sept. 24, 1943, had had chronic sinusitis for four years, and four weeks before entry a right intranasal maxillary antrotomy was performed. A week later pain and swelling developed in the soft tissues overlying the antrum. A wisdom tooth was removed, allowing pus to drain into the mouth through the empty socket, but the pain and swelling of the face did not subside. Sulfathiazole 6 Gm. a day for two weeks was administered in another hospital with no improvement. On entry the temperature was 38.5 C. (101.3 F.), pulse rate 86, respiratory rate 16 and blood pressure 115/70. The patient, a slender woman in good general physical condition, was very uncomfortable because of the pain and swelling of the face. The right eye was nearly shut, and the swelling extended down to the mouth, obliterating the nasolabial fold. The overlying skin was red and glistening, and there was definite fluctuation just below the eye. In the mouth, thick yellow pus was draining from the empty tooth socket and from a small fistula in the center of the hard palate. The right nostril was filled with thick yellow purulent exudate. Apart from these local findings, physical examination revealed no abnormalities.

The red blood cell count was 4,100,000; hemoglobin, 70 per cent; white blood cell count, 12,200, with a normal differential count; the erythrocyte sedimentation rate (Wintrobe) was 44 mm. per hour; packed cell volume was 38, and the urine was normal.

Details of the course in the hospital are shown graphically in the accompanying chart. The day following entry a continuous intravenous infusion of penicillin was begun, and two hours later an operation was performed. Widespread destruction of the right maxilla required extensive removal of the lateral and inferior aspects of the maxilla, including the hard palate nearly to the midline. The antrum was filled with pus, and the pterygoid plate, roof and posterior wall of the antrum were removed. The soft tissue abscess of the face was found to drain freely into the space left by removal of

From the Departments of Medicine and Surgery (Otorhinolaryngology), Stanford University School of Medicine.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigation recommended by the Committee on Chemotherapeutics and Other Agents of the National Research Council.

bone, and for this reason no external incision was made. Devitalized bone was removed as completely as possible, the sharp edges were smoothed, and the entire cavity was packed with iodoform gauze.

Cultures of bone removed at operation revealed a heavy growth of anaerobic nonhemolytic streptococci. Sections of the bone showed areas of necrosis and inflammation indicative of subacute osteomyelitis.

Administration of penicillin 200,000 units a day by continuous intravenous infusion in 1 liter of isotonic solution of sodium chloride was continued during operation and afterward for five days, a total of 1 million units. Two transfusions and fairly heavy sedation were the only other therapeutic measures. There was, during this five day period, a dramatic diminution of the swelling and tenderness of the face, but a recurrence was predicted because denuded, apparently necrotic, maxillary bone could be palpated with forceps along the infraorbital ridge, high in the cavity left by the operation.

After five days penicillin therapy was instituted for the third time because of a recurrence of swelling, tenderness and pus at the local site. A pure culture of anaerobic nonhemolytic streptococci was obtained from the pus. After seven days' treatment by the subcutaneous route approximately 100,000 units daily, the patient was again operated on. In addition to extraction of all remaining portions of apparently devitalized maxillary bone along the infraorbital ridge, the right upper central incisor and the remainder of the right side of the hard palate were removed. There was again a severe postoperative febrile reaction, probably due to impurities in the penicillin solutions. The penicillin was discontinued two days after the operation, a total of 900,000 units during this ten day course, and a final total of 2,690,000 units since entry. The temperature quickly returned to normal, and this time the swelling and tenderness did not recur. The facial incision healed rapidly, and the patient left the hospital ten days after the last operation. Cultures of the cavity in the mouth still revealed a heavy growth

Course in case 1.

Three days after the penicillin was stopped there was a sudden reappearance of pain and swelling below the right orbit, and an external incision 4 cm. in length was made parallel to, and 0.5 cm. beneath, the lower margin of the orbit. The soft tissues were edematous, but little frank pus was encountered. Cultures revealed large numbers of both anaerobic nonhemolytic streptococci and *Staphylococcus aureus* (coagulase positive). The underlying maxillary bone was denuded of periosteum, but no bone was removed because definite sequestration had not yet occurred. The wound was packed open with iodoform gauze and penicillin therapy was begun by the continuous intravenous route, 50,000 units a day. A severe febrile reaction, probably caused by pyrogenic saline solution in which the penicillin was mixed, necessitated a change to the continuous subcutaneous route after 175,000 units had been administered. A total of 810,000 units was given intravenously and subcutaneously during this course of eleven days. Again the swelling and tenderness disappeared completely, and very little pus was present in the wound. Cultures were repeatedly positive for *S. aureus* (coagulase positive) and anaerobic nonhemolytic streptococci.

of anaerobic nonhemolytic streptococci and *S. aureus* (coagulase positive).

During a six months follow-up period the patient has remained entirely well and is now having a prosthesis made to replace the bony structures which were removed surgically.

CASE 2.—*Failure of sulfonamides and extensive surgical procedures to cure osteomyelitis of maxillary bone following sinusitis; prompt response to penicillin, with several relapses; complete cure with penicillin plus removal of all foci of dead bone.*

B. P., a man aged 23, a dyecaster, who entered the San Francisco City and County Hospital in December 1942, suffered from acute right frontal sinusitis and osteomyelitis of the frontal bone. Surgical exploration revealed a widespread purulent destruction of the frontal bone and a large extradural abscess. Approximately one-half the frontal bone was removed to well beyond the limits of infected bone, and both frontal sinuses were obliterated. The T shaped incision was packed open for the following two months, during which time convalescence was uneventful. A secondary closure of the wound was then accomplished with excellent healing except for a small

persistent fistula in the midline at the juncture of the flaps. Three months after entry the patient was discharged and thereafter followed regularly in the Stanford University outpatient clinic. All attempts to close this fistula met with failure. Repeated x-ray studies revealed a persistent left anterior ethmoiditis and after much investigation it was felt that the fistula was being fed by this ethmoid infection. In July 1943 the patient entered Stanford Hospital, where external ethmoidectomy and excision of the fistulous tract was performed. *S. aureus* was cultured from the operative area. Convalescence was uneventful, and the patient was discharged on the sixth postoperative day. Twelve days after the operation he complained of frontal headache and pain in the left malar region. Examination revealed tender swelling along the left infraorbital ridge and swelling of the operative wound with slight fluctuation. The patient reentered the hospital, where the wound was opened widely, releasing a small amount of purulent discharge. Palpation of the depths of the wound with forceps revealed the frontal process of the left maxilla to be denuded of periosteum, and *S. aureus* was again isolated from the pus. These findings seemed to indicate an osteomyelitic process proceeding along the superior ramification of the left maxilla. Full doses of sulfadiazine (6 Gm. a day) were given over the following eighteen days, and supportive treatment consisted of blood transfusions, vitamin therapy and a high calory diet. Excellent drainage was secured from the infected area. In spite of this treatment the patient's temperature was septic, he appeared very toxic and continued a steady downhill course. The left intraorbital swelling progressed slowly until the left eye was entirely closed and the malar swelling extended into the left temporal region. X-ray examination revealed an early destructive process extending along the left infraorbital ridge laterally to the infraorbital foramen.

S. aureus and anaerobic nonhemolytic streptococci were cultured on two occasions from pus expressed from beneath the swollen area through a small opening just below the medial side of the left orbit. Since sulfonamide therapy seemed ineffectual in controlling the spread of the disease, penicillin was begun on August 30 by continuous intravenous drip, 60 units per cubic centimeter, a total of 50,000 units in seventeen hours. Because of venous thrombosis, a change was then made to the continuous subcutaneous route, 100,000 or 200,000 units daily, a total of 1,385,000 units in twelve days. There was decided subjective improvement within twelve hours after the penicillin was started, and during the next ten days the pain and swelling disappeared completely. Daily cultures revealed *S. aureus* and anaerobic nonhemolytic streptococci for five days, *S. aureus* alone for the next three, and thereafter the drainage ceased altogether.

Five days after penicillin was stopped the pain and swelling recurred, accompanied by a temperature rise to 38.2 C (100.7 F) and white blood cell count of 9,600. Penicillin was started intravenously 200,000 units daily for five days, and the incision below the medial side of the left eye was extended laterally 1 centimeter beyond the infraorbital foramen. Pus obtained at the operation contained only anaerobic nonhemolytic streptococci. Again the swelling and pain promptly subsided, but penicillin therapy was reinstituted after a four day interval, 100,000 units daily for three days, in conjunction with the surgical removal of a sequestrum through the facial incision. The patient then went home but returned again ten days later with swelling and inflammation below the left eye. After five days of continuous penicillin therapy, partly intravenous and partly subcutaneous (total, 320,000 units) he was clinically well and left the hospital because of the death of his mother. Two small sequestra were removed from the outer edge of the wound during this hospitalization. Ten days later there was another typical recurrence, and this time packs soaked with penicillin 100 units per cubic centimeter were placed in the wound every three hours for four days. Surgical exploration revealed two more small sequestra in the outer edge of the wound, but the underlying exposed bone appeared healthy when they were removed. The wound closed quickly when the packs were discontinued, and the patient went home on October 27, having received a total of 3,010,000 units of penicillin. He has been entirely well during a follow-up period of over five months.

CASE 3—Cellulitis of jaw following tooth extraction, involvement of orbit with protrusion and blindness, and osteomyelitis of frontal bone, cure with penicillin after failure with surgical procedures and sulfonamides

G. S., a white man aged 38, a farmer, developed a painful swollen right jaw in September 1943 three days after the extraction of two upper molar teeth. The cellulitis spread rapidly, causing protrusion and complete blindness of the right eye. On September 30 he was admitted to another hospital, where his temperature was 106 F, and x-ray examination showed clouding of the right antrum but no signs of osteomyelitis. After two weeks of therapy with full doses of sulfadiazine he went home much improved but returned four days later with a recurrence of fever, headache and periorbital swelling. X-ray examinations now showed involvement of the right sphenoid and ethmoid cells as well as of the right antrum. During the next two months he was given repeated courses of sulfonamides, and several subcutaneous abscesses below the right eye were drained surgically. On December 5 an incision was made through the right brow, releasing 5 cc of creamy pus, and the underlying bone was covered with granulation tissue. It was felt that the infection had spread from the lateral wall of the right antrum up along the anterior portion of the lateral wall of the orbit. *Staphylococcus albus* (coagulase positive) was cultured from the pus. Following this operation there was again improvement, but he was transferred to Stanford Hospital when the pain and swelling recurred on December 20. The temperature was normal, but there was a definite protrusion of the right eye with eversion of the lower lid and conjunctivitis. A small abscess below the eye was drained and *S. albus* (coagulase positive) was again cultured. X-ray examination revealed cloudiness of the right antrum and ethmoids and both frontal sinuses. There were slight but definite osteomyelitic changes of the frontal bone in the region of the right temporal fossa, and pitting edema was noted over this area. A right intranasal antrotomy was performed, and penicillin was administered by the continuous intravenous route 200,000 units daily for eight days. Intramuscular injections of 15,000 units every three hours were then given for nineteen days, a total of 3,650,000 units by both routes. During this time the redness, pain and swelling disappeared altogether, although the proptosis remained and the x-ray changes persisted. After three weeks at home he returned on Feb. 15, 1944 with a corneal ulcer and diffuse conjunctivitis of the right eye, resulting from insufficient protection afforded by the everted lower lid. In addition to local treatment he received 840,000 units of penicillin intramuscularly over a period of a week. During a follow-up period of two months there has been no evidence of recurrence of infection, and the cornea has been protected by dark glasses and merthiolate ointment. A plastic repair of the lid will be performed at a later date.

CASE 4—Osteomyelitis of frontal bone and brain abscess following sinusitis, stormy course with convulsions and paralysis of the left arm and leg following surgical operation, cure with prolonged penicillin therapy and aspiration of a second brain abscess

During the second week of December 1943 J. C., a white man aged 51, developed acute frontal sinusitis with severe headache and photophobia. The pain became progressively worse in spite of chiropractic treatment, and a swelling of the soft tissues appeared above the right eye. A typical grand mal seizure on Jan. 12, 1944 prompted transfer to Stanford Hospital, where the patient was found to be semistuporous and had a temperature of 40.5 C (104.9 F). There was stiffness of the neck, but no abnormal reflexes were elicited. Pitting edema was noted over both eyebrows, especially on the right. The white blood cell count was 22,400 and the spinal fluid contained 1,000 cells per cubic millimeter, all polymorphonuclears. Both the blood and the spinal fluid were sterile at this time. A continuous intravenous infusion of penicillin was begun, 100 units per cubic centimeter, and at operation he was found to have right frontal sinusitis with osteomyelitis, extradural and subdural pus, and an abscess of the right frontal lobe. The affected bone was removed as completely as possible, and drains were placed in the abscess cavity. The whole area was irrigated with penicillin solution, and the wound was

covered with penicillin saturated gauze. Anaerobic nonhemolytic streptococci were cultured from the right frontal sinus and brain abscess. Postoperatively penicillin was administered by the continuous intravenous route 300,000 units daily for eight days, and the head wound was irrigated two or three times daily with penicillin 100 units per cubic centimeter. During this time the course was stormy, with continued high fever, clonic convulsions at frequent intervals, periods of Cheyne-Stokes respiration and a flaccid paralysis of the left arm and leg. On January 18 a few nonhemolytic streptococci were cultured from the spinal fluid, and the next day 10,000 units (1,000 units per cubic centimeter) of penicillin was instilled intraspinally. All other cultures of the spinal fluid were sterile. Penicillin was discontinued because of a generalized maculopapular erythematous rash, which appeared six days after therapy was instituted and became progressively worse. After fading promptly, the rash reappeared six days later, when 180,000 units of penicillin from the same manufacturer was administered intramuscularly in thirty-six hours. It again faded promptly and was apparently a dermatitis medicamentosa caused by a certain lot of penicillin. The patient remained disoriented and semicomatose and on February 2 passed into a deep coma, with irregular heart beat and respirations. Pus (8 cc.) was aspirated from a second brain abscess located posterior to the first in the prerolandic area; cultures again revealed anaerobic nonhemolytic streptococci. Penicillin 100 units per cubic centimeter was instilled into the cavity, and no pus was obtained when a second aspiration was attempted three days later. Since it seemed imperative, penicillin therapy was again started, preparations other than the preparation which had previously caused the rash being used, and this time there was no recurrence of dermatitis. The wound was irrigated three times a day with 5 and 10 cc. (100 units per cubic centimeter) and 15,000 units was injected intramuscularly every three hours. Beginning with the aspiration of the second brain abscess and the reinstitution of penicillin therapy there was slow but steady improvement. The spinal fluid, at first cloudy and under increased pressure, gradually cleared so that daily taps were no longer necessary. Convulsions ceased, the patient regained his mental faculties and the paralysis of the left arm and leg gradually disappeared. The exposed anterior pole of the right frontal lobe of the brain prolapsed through the wound at first and became covered with purulent granulations. As this tissue became necrotic it was gently wiped away with sterile gauze. The brain then gradually receded and for two weeks, from February 24 until March 9, a profuse leakage of cerebrospinal fluid occurred from the wound; this gradually decreased and ceased spontaneously. Penicillin was finally discontinued on March 16, two months after the patient was admitted to the hospital. At this time the wound was clean and epithelium was beginning to cover the healthy granulation tissue. Mentally there was complete recovery, and the left arm and leg had regained much of their original strength. The total amount of penicillin administered locally and parenterally was 7,540,000 units.

CASE 5.—Osteomyelitis of frontal bone following surgical operation for frontal sinusitis; failure to respond to sulfonamides, with fever and bacteremia; prompt response to penicillin; sequestrectomy later with a second course of penicillin.

E. A., a man aged 53, developed a swelling over the right eye in March 1943, which subsided in four days. In September the pain and swelling recurred and this time did not respond to conservative therapy. On October 21 in another hospital both frontal sinuses were opened widely and the anterior ethmoid cells removed. Two weeks later the patient developed a low grade fever, headaches and edema over the frontal bones. Subacute osteomyelitis was diagnosed, and the process continued to spread in spite of intensive therapy with sulfonamides. He entered Stanford Hospital Jan. 21, 1944 with a temperature of 38.5 C. (101.3 F.), pitting edema over the forehead and a draining sinus above the medial side of the right eye. Anaerobic nonhemolytic streptococci were cultured from the blood and from the draining sinus; *S. aureus* (coagulase positive) was also isolated from the latter site. The blood count was normal, but both the blood and the spinal fluid Wassermann reactions were positive. X-ray examination showed an exten-

sive widespread, moth-eaten destruction of the frontal bone, most pronounced on the right. A continuous intravenous infusion of penicillin was started January 22, 200,000 units daily for twelve days, a total of 2,400,000 units. Intramuscular injections were then given, 15,000 units every three hours for a week, a total of 760,000 units. For the first eight days, penicillin (100 units per cubic centimeter) was also injected into the draining sinus, 4 to 10 cc. twice a day. During this time his temperature subsided to normal, headache disappeared and drainage ceased. He left the hospital but returned on February 29 for the removal of several large sequestrums of the frontal bone through an incision just above the right eyebrow. In conjunction with surgical operation intramuscular penicillin was again given, 120,000 units daily for fourteen days, a final total of 4,847,000 units for both entries. *S. aureus* (coagulase positive) was cultured from the sequestrums, and sections showed changes characteristic of chronic osteomyelitis with sequestration. The postoperative course was uneventful, but x-ray examination revealed that not all of the sequestrums had been removed. The wound is now healed and the patient is entirely well, but the follow-up period of six weeks is too short to be sure that there will be no further recurrences. The course of the asymptomatic neurosyphilis will also be followed with great interest.

COMMENT

The fundamental principles underlying the treatment of osteomyelitis of the facial bones are well illustrated by these 5 cases. In contrast to the sulfonamides, penicillin prevents further spread of the infection, so that either before or after sequestration has occurred devitalized bone can be removed surgically. Relapses are likely to occur until all the necrotic bone is gone. Surgical procedures are probably best postponed until the patient has had three or four weeks of penicillin therapy and sequestration has occurred, since there is then a better possibility of removing all the devitalized bone at one time.

Penicillin dosage is still controversial. The first 2 patients were given small amounts for only a few days, as a result of which there were frequent relapses. Prolonged treatment with larger doses prevented relapses in the other 3 cases and possibly shortened the course of the disease. The present policy in this clinic is to administer 200,000 units daily by continuous intravenous drip for ten days to two weeks, followed by 15,000 units intramuscularly every three hours (120,000 units daily) for another two or three weeks. If surgical treatment is delayed until sequestration has occurred, penicillin should be continued for at least a week postoperatively.

The only toxic reaction observed was a generalized maculopapular rash (case 4), which appeared six days after treatment was begun and faded promptly when penicillin was discontinued. The rash did not recur when the patient was given penicillin prepared by a different manufacturer.

In cases 1, 2, 4 and 5 anaerobic nonhemolytic streptococci were probably primarily responsible for the osteomyelitis, with *S. aureus* (coagulase positive) also present in cultures from sinuses communicating with the skin. These same organisms were isolated by Williams and Nichols,¹ who also report excellent results with penicillin. *S. albus* (coagulase positive) was the only organism recovered in case 3.

The results in these 5 cases would seem to justify the hope that the present high mortality rate in cases of acute, subacute and chronic osteomyelitis of the facial bones will be drastically reduced when supplies of penicillin become generally available.

SUBACUTE BACTERIAL ENDOCARDITIS

INHERENT DIFFICULTIES IN PROGNOSIS; A REPORT
OF TWO RECOVERIES AND TWO DEATHS

WILLIAM HALL BUNN, M.D.

YOUNGSTOWN, OHIO

Since the advent of sulfonamide therapy, a slowly increasing number of carefully studied patients who have recovered from subacute bacterial endocarditis have been the subject of reports. Patients living and well one year after treatment are considered recovered. The most discouraging report comes from Galbreath and Hull,¹ who had 42 deaths in 42 patients treated with sulfonamides. The experiences of Smith, Sauls and Stone² are more encouraging. They add two cures to the 35 authentic instances of recovery which they could find in the literature.

Several plans of treatment, all utilizing the sulfonamide drugs, have been described. Bierman and Baehr³ report some successes with combined physically induced pyrexia and chemotherapy. I have used this method on 2 patients, both of whom died but not for several weeks after hypertherm treatment was discontinued. These 2 fatal cases are briefly summarized to illustrate the point that treatment was vigorous and yet of no avail.

FATAL CASES

CASE 1.—Mrs. M. C., aged 33, a private patient hospitalized June 7, 1941 in Youngstown Hospital, had rheumatic fever at the age of 10. Fourteen weeks before admission to the hospital she had several teeth removed. Her symptoms of fever, malaise and chilliness developed soon after this dental experience. Blood cultures were found positive for *Streptococcus viridans* on three different occasions. She was given sulfonamide drugs totaling 65 Gm. in a period of nine days. The blood sulfadiazine level was as high as 27.4 mg. per hundred cubic centimeters. During this period of high concentration of the drug in the blood, hypertherm treatments were given in the Kettering fever therapy cabinet. The body temperature was elevated 105 to 106 F. each day. The patient died at home approximately two months after the last treatment. There was a short remission of symptoms and signs for a period of one week following intensive treatment.

CASE 2.—M. M., a Negro girl aged 17, admitted to Youngstown Hospital, South Side Unit, Jan. 24, 1943 with the history of a previous admission at the age of 12 for treatment of rheumatic fever and endocarditis, had been examined in the heart clinic in 1941 because of "spitting of blood clots." X-ray examination of the lungs was negative at that time. Aortic and mitral diseases were present. She had an uneventful pregnancy and labor with a living child in March 1942. Three weeks before admission she was said to have had pneumonia. The provisional diagnosis on admission was subacute bacterial endocarditis. This was confirmed by the clinical course and five blood cultures positive for *streptococcus viridans*. During her four months in the hospital a total of 236.5 Gm. of sulfonamide drugs was given. The highest blood level was 19.3 mg. of sulfadiazine per hundred cubic centimeters. The patient was in the hypertherm cabinet ten times, the temperature each time varying between 105 and 106 F., for a total of nineteen and one-half hours. Five blood transfusions averaging 370 cc. were given by the indirect method. The patient died on

May 10, 1943, twenty-four days after the last hypertherm treatment, with no evidence that treatment had influenced the course of the disease in any manner.

Orgain and Poston⁴ stress the importance of preliminary in vitro experiments to determine the most effective drug and its optimal chemical level of inhibitory action.

In the report of Dick⁵ the patient had an initial infection of his right hand, as did 1 of my patients. Dick gave 40 Gm. of sulfadiazine in one dose, a method which was found ineffective by Hull, Bayley and Holoubek.⁶

CASES WITH RECOVERY

I have had 2 cases of subacute bacterial endocarditis in the past three years in which recovery occurred. These 2 are reported together because of certain contrasts. The first record is of a man shown in person at the 1941 meeting of the American Heart Association in Cleveland. He had a definite rheumatic fever history and may be fairly classified as presenting a classic example of subacute bacterial endocarditis.

The second case had a much more abrupt onset and had as a predisposing factor a patent ductus arteriosus. This case is particularly interesting at the present time because of the possibility of preventing further attacks by tying off the patent ductus. Both cases were treated with sulfonamide therapy, one with moderate doses over a long period of time and the other with larger doses given intravenously for seven weeks. Both of these patients are living and have been at work for more than one year.

CASE 3.—F. W. B., a man aged 47, was first examined in 1934, when he observed that he was too tired after his usual tennis game. No enlargement of the heart and a soft diastolic aortic murmur were recorded at that time. On the basis of a history of a severe attack of rheumatic fever with "dropsy" and a "murmur" at the age of 12, the diagnosis of chronic rheumatic valvulitis was made. The patient was instructed to reduce his physical activities; this restriction he accepted. He was urged to use less nicotine than two packs of cigarettes a day; this advice he did not accept. He was comfortable until 1936, when he had a stormy painful seizure of renal colic and passed a small calculus. In 1936 he had an appendectomy with uneventful recovery. There were no signs of increase in the pathologic condition of the heart noted at that time.

In October 1939 he developed a painful fibrositis and tenosynovitis in his left forearm. He had not completely recovered from this illness when on a stormy week end he took a 400 mile automobile trip to a football game. He "caught cold" and developed precordial pain, which, though not severe, was persistent and annoying. From this time on he was "too tired all the time." He was not seen by a physician until February 1940, when he developed an upper respiratory infection during the unusually cold weather in Florida, where he had gone "to try to get strong." He was quite ill for two weeks and then "not well enough to get around" until he came north in May. He entered a hospital in Cleveland, where the diagnosis of subacute bacterial endocarditis was made and confirmed by three blood cultures positive for *Streptococcus viridans*.

On May 21, 1940 he came under my care with all the classic signs of subacute bacterial endocarditis. He was given sulfa-

thiazole, which at that time was obtainable only for investigational use. This preparation, furnished gratis by Merck & Co., was administered by mouth in gradually increasing doses up to 7.5 Gm. daily for one month. Fourteen days of this

in more strenuous activities than the average youngster. During her school years she had been one of the best players on a girls' baseball team and had never noted loss of cardiac reserve. She had no history of having had rheumatic fever, chorea, scarlet fever or any disease which might have been interpreted as a rheumatic manifestation.

On Feb. 6, 1942 she reported to the plant dispensary because of two furuncles on the inner side of the right forearm and a moderately diffuse swelling of the right palm, most prominent at the base of the second finger. She was given x-ray treatment of 100 roentgens over the infected areas.

On February 7, because of a moderate lymphadenitis, the palmar infection was opened and a very small amount of thick creamy pus was obtained from just under the skin. All local signs of infection promptly subsided. The temperature and pulse, which had been slightly elevated, returned to normal.

On February 16 she had a temperature of 101 F. There was tenderness over one gland in the right axilla. She had two doses of sulfathiazole but refused to take more because of nausea. Because of the persistence of fever, sulfathiazole was again administered from February 24 to March 3, a total of 18.5 Gm. being ingested during this period.

The patient was admitted to the City Hospital in Warren, Ohio, on March 4, 1942 with a provisional diagnosis of septicemia. Her temperature on the evening of admission was 101.8 F. and the pulse rate 114. On the next day the white

Fig. 1.—Pertinent data in case 3.

month were spent in the hospital. The drug was discontinued on June 21, 1940 for a period because of hematuria. A total of 41 Gm. had been ingested up to that time. The details of the pulse, temperature, white blood count, sulfathiazole level and daily amount of sulfathiazole given during his hospital stay are shown in figure 1. In addition to leukocytosis, elevated temperature and rapid pulse the patient had a tender spleen, splinter hemorrhages under the nails and evidences of emboli on the trunk and extremities. The aortic diastolic murmur recorded first in 1934 was of the same quality as noted at that time. Precordial pain was a troublesome symptom. No friction rub was heard, but the character and distribution of the pain suggested an acute pericarditis.

The patient was in bed all of May and June 1940. He returned to work Aug. 15, 1940 and has been actively engaged as an executive since that time. During this past busy season he has worked overtime almost every day. On his own initiative he took a daily dose of at least 1 Gm. of sulfathiazole for one year following his illness. He was readmitted to the hospital in 1941 for cardiovascular examination. His heart had changed but little in size since the original examination in 1934. The aortic diastolic murmur was of the same quality, but a mitral systolic murmur was heard at the apex of the heart. This was not present during his illness of 1940. It is, I believe, clear evidence of a mitral valvulitis which developed during his septicemia.

CASE 4.—I. T., a woman aged 21, a worker in a glass factory, was noted by the examining physician as having a "heart murmur" at the time she was hired in 1941. She had been told in early childhood that she had "heart trouble." In spite of warnings by family and physician, she had engaged

Fig. 2.—Details of treatment and response in case 4.

blood cell count was 3,900, hemoglobin 60 per cent and red blood cell count 3,840,000. The blood culture on March 6 (two days after admission) was positive for streptococcus. Positive cultures were obtained on March 6, March 7 and March 9. All of these were subcultured and found to be *Streptococcus viridans*.

7. Dr. Paul Gauchat of Warren, Ohio, gave me permission to report this case, which I saw in consultation several times in March 1942. Dr. Gauchat made the x-ray studies and carried the burden of the routine treatment.

On March 7 the patient had a chill. The temperature was 103.8 F. A record of the clinical course and treatment during the period of the most serious illness (March 7 to March 28) is shown in figure 2.

Sulfathiazole therapy was resumed on March 8, but the patient was unable to retain it because of nausea and vomiting. Large doses of sodium sulfathiazole were then given intravenously beginning March 9.

Repeated small blood transfusions seemed indicated on account of the severe anemia present on admission and because favorable clinical effects were noted following transfusions during the most critical period of the illness.

Because of severe dehydration, liberal quantities of fluid, as much as 6,000 cc. in twenty-four hours, were given orally and parenterally. This may be one reason for the lack of high concentration of sulfathiazole in the blood, for at no time did this exceed 6 mg. per hundred cubic centimeters. There was another factor influencing the blood sulfathiazole level. The patient had exceedingly small veins, so that there was considerable mechanical difficulty in giving fluids and obtaining specimens of blood for tests. The plan evolved was to take the blood specimen for laboratory purpose through the same needle through which the drug was given, but just before sodium sulfathiazole was injected. This meant that the test was taken twelve hours at least after the time when the highest concentration of the drug might have been expected in the blood.

There were two crops of petechial hemorrhages involving both feet on March 10, and multiple petechiae appeared on the hands and feet on March 12.

Because of persistent and repeated emesis, sulfathiazole was discontinued on March 13, and the patient was given sulfadiazine by mouth.

On March 18 the patient developed a pleural friction rub at the base of the right lung. This radiated to the right shoulder. There was clinical and x-ray evidence of considerable effusion in the right pleural cavity with a fluid level at the seventh rib. On March 23, 50 cc. of straw colored fluid for diagnostic purposes was removed from the right pleural cavity.

There was a palpable inguinal gland noted on March 26, and phlebitis of the veins of the left calf appeared the next day. Both of these complications subsided promptly and completely.

General clinical improvement was evident on March 26. At this time a disturbing leukopenia developed, and sulfadiazine was discontinued. The temperature became normal on March 28, and from then on recovery was uneventful.

During the period of her highest temperature, most rapid pulse rate and greatest toxemia it was my impression that the murmur at the base of the heart and at the apex changed in quality, the typical murmur of patent ductus arteriosus being harsher and more easily heard than on first examination and the systolic murmur at the apex much louder and more prolonged.

The patient left the hospital on May 16, 1942, two months and twelve days after admission. She felt well and was strong enough to walk about. There were no clinical signs other than the persistence of the continuous machinery-like murmur of patent ductus arteriosus at the base, and the soft systolic apical murmur. The electrocardiogram showed no significant departure from normal. The blood pressure was 120 systolic and 80 diastolic, the pulse rate 78 and the cardiac rhythm normal.

One year ago the patient was able to return to work (Aug. 3, 1942). To date there has been only one interruption of her normal life and that was due to a sharp attack of pyelitis on Sept. 25, 1942, which caused chills and high fever for three days and kept her from work for one week. Her chief worry at the present time is her excessive gain in weight.

COMMENT

No explanation can be given at this time for the beneficial effects of sulfonamides in the recovered patients, when 12 other cases treated during the same period have failed to be influenced in the least by similar or more intensive treatment.

One very sound reason for not being too optimistic about the cure of subacute bacterial endocarditis with sulfonamide compounds or any other substance is autopsy experience. When hearts such as the one

Fig. 3.—Heart of patient dying of subacute bacterial endocarditis. Note large left atrial mural thrombus. Destruction of mitral valve by vegetation.

shown in figure 3 are studied, the futility of treatment in similar cases must be acknowledged. Large adherent mural thrombi and multiple valve vegetation, such as those shown here, constitute depots of continuous infection which no known treatment can conceivably conquer.

In the authentic cases of recovery reported probably there was little structural damage and the infection was due to a type of streptococcus which had low resistance to the sulfonamide drugs. Our inability to recognize in advance the incurable cases makes it obligatory to treat vigorously all patients having subacute bacterial endocarditis with one of the sulfonamide drugs. Though few, these favorable results enable us to offer some hope to those who heretofore had no chance for recovery.

603 Home Savings & Loan Building.

First Accurate Medical Historian.—Thucydides (471-400 B. C.) is the first accurate medical historian. His description of the plague at Athens is, he tells us, that of an eye witness. As you study it, ask yourself the question "How would I describe an epidemic that was new and strange and struck my own city? What facts would I record and in what order?" Then notice how completely Thucydides covers the ground. In spite of the careful description of the signs and symptoms, however, it is not possible to identify positively Thucydides' plague. W. H. S. Jones thought it was malaria. More likely it was bubonic plague. The ancient and medieval world was the stage for many destructive epidemics. Both bubonic plague and influenza cause intense cyanosis, so either could have been "the black death." After Thucydides, the great plagues were (1) that following the eruption of Vesuvius, A. D. 79, which destroyed Pompeii; (2) the plague of Orosius, A. D. 125, preceded by an invasion of grasshoppers which spread over Italy and northern Africa, Carthage and Utica; (3) the plague of Antoninus, A. D. 164-180, all over the Roman Empire; (4) the pestilence of Cyprian, A. D. 251-266, probably smallpox; (5) the black death appeared in Europe about 1348, and repeated its visitations too often to mention.—Clendening, Logan: *Source Book of Medical History*, New York, Paul B. Hoeber, Inc., 1942.

A PANORAMIC VIEW OF THYROTOXICOSIS

REGINALD FITZ, M.D.
BOSTON

(Concluded from page 947)

POST-THERAPEUTIC HYPOTHYROIDISM

Table 4 summarizes results which developed in 5 cases in which treatment directed to the thyroid gland appeared to result in the fairly prompt development of perceptible hypothyroidism. As a rule, postoperative hypothyroidism became manifest within a comparatively short time and thyroid was helpful in therapy. But none of the patients claimed to feel as well after developing hypothyroidism as when they were normal, so that, on the whole, the development of hypothyroidism as a complication of thyrotoxicosis was by no means a fortunate occurrence.

This impression is of some interest. Such surgeons as Poate and Wyndham,¹⁹ Dobson, Seely and Rose,²⁰ Berlin and Gargill²¹ and Albright and Clute,²² who have reported recently on the end results in thyroid

TABLE 4.—Development of Hypothyroidism in Patients Treated for Hyperthyroidism

Case No.	Treatment of Hyperthyroidism	Date of Present Note	Comment
1	Irradiation	4 years later	Basal metabolic rate —10 two years after; now fairly comfortable on thyroid
18	Subtotal thyroidectomy	15 years later	Feels cold, tires easily and has poor memory; fairly comfortable with thyroid; basal metabolic rate —18
26	Subtotal thyroidectomy (thyrocardiae)	6 years later	Hypothyroidism recognized six years after operation; fairly comfortable with thyroid; weight now 73.5 Kg.
27	Subtotal thyroidectomy	12 years later	Hypothyroidism recognized a year after operation; manages to be fairly comfortable with judicious use of thyroid
30	Subtotal thyroidectomy	7 years later	Hypothyroidism recognized a year after operation; takes thyroid regularly and feels fairly well but always less than normally energetic and active

surgery, have encountered postoperative hypothyroidism in a certain proportion of their cases and seem to make but little of it. Indeed a truly radical surgeon like Scott²³ appears to advocate so total a subtotal thyroidectomy in his most toxic cases as seemingly to aim for postoperative hypothyroidism.

Even those patients reported in table 3 who apparently obtained excellent results from therapy are not all entirely happy, since the ones who have gained so much weight as to become obese are not normal individuals; they admit that they are never perfectly well, are less efficient than they were before they became ill and claim to find it unduly hard to lose weight by diet restriction. Those who are hypothyroid are even more conscious of their liabilities; unenergetic, sluggish,

perhaps having found it difficult to bear normal children, and in general almost as much handicapped by being forced to rely on thyroid as is the diabetic patient who has to rely on insulin.

The duration and true significance of hypothyroidism developing as the result of treatment in thyrotoxicosis is difficult to appraise because many bizarre happenings may occur in connection with it. For example, Wilson and Mayo²⁴ saw 2 cases of clinical postoperative myxedema that later became hyperthyroid. Haines's²⁵ and Zondek's²⁶ cases are very similar. Not long ago, however, I saw a patient who gave me much food for thought:

B. M. developed the clinical picture of thyrotoxicosis when she was 28 years old. She then had a subtotal thyroidectomy; her basal metabolic rate was +69 and, according to the pathologic report of Dr. Shields Warren at the time, the gland showed primary hyperplasia with a moderate degree of strumitis.

She felt very well for several years after the operation except that she developed gallstones, which were treated successfully. I first saw her twelve years after her thyroidectomy, through the courtesy of Dr. Howard M. Clute. She had gained a great deal of weight and now looked like a person with hypothyroidism. Her basal metabolic rate had fallen to —18, and the blood cholesterol was 230 mg. per hundred cubic centimeters. She was advised to take thyroid and to diet carefully in order to lose weight.

For the ensuing four years she felt well, never bothering, however, to take thyroid regularly. Then she began to notice that she was becoming hoarse and was losing all her energy. Finally she returned to me for examination, nineteen years after operation. She had a basal metabolic rate of —37 and gave every appearance of myxedema.

I described her predicament to Dr. Warren and asked him to review her thyroid sections. He says that, in light of present knowledge, he believes it would have been possible to prophesy from the way her thyroid gland looked when he studied a section from it nineteen years ago that she was likely to develop myxedema if she lived long enough. For now he suspects that she had from the beginning a pathologic condition more like the early stages of that peculiar form of thyroid disease called struma lymphomatosa than ordinary toxic diffuse goiter.

In the literature have been reported other hints such as this which suggest that the experienced pathologist of today, if he had the chance, could spot for his surgical colleagues at the operating table those patients particularly liable to develop hypothyroidism after partial thyroid ablation. Plummer and Boothby,²⁷ for instance, before the days of iodine felt reasonably certain that the incidence of postoperative myxedema in thyrotoxicosis was more or less proportional to the degree of lymphocytic infiltration and fibrosis which happened to be present in the thyroid gland at the time of operation. It is not impossible, therefore, that preoperative biopsy with careful study of the thyroid gland before any more radical operation might be of material help in guiding treatment. Certainly the prevention of posttherapeutic hypothyroidism would be a distinct advance in the treatment of thyrotoxicosis.

RECURRENT TOXIC GOITER

Table 5 summarizes the results in 3 cases with true recurrences necessitating operative treatment. It is interesting that in 1 instance no appreciable recurrence occurred until seven years after thyrotoxicosis was first recognized and treated by surgical means. This is not unusual, and one can easily assemble curious stories along this line. A certain woman now 57 years old was operated on for hyperthyroidism in 1913, thirty-one years ago. She did well for eleven years, until 1924, when she had a recurrence with a second operation. Eight months later she had a third recurrence, which also was treated by surgery. The disease then was quiescent for eight years. But in 1932 a fourth recurrence developed, and since then her thyroid gland appears to have behaved itself.

Fig. 2.—End result on the thyroid gland of thyrotoxicosis treated by surgery. Section of the same thyroid gland that was shown in figure 1 obtained at necropsy ten years later. The remnant weighed 11 Gm. The acini are dilated. The epithelium is low cuboidal. There is considerable increase in connective tissue. The gland appears atrophic rather than hyperplastic. Reduced from a photomicrograph with a magnification of 50 diameters. (Courtesy of Drs. Shields Warren and S. B. Wolbach.)

The frequency with which recurrences develop after any form of treatment varies but is always a sore point. Coller and Potter²⁸ have described the situation clearly; in light of present knowledge thyrotoxicosis, they admit, is due to an unknown exciting cause. The surgical approach is to interrupt a vicious circle through an attack on hyperactivity of the thyroid gland, this being one known factor in the circle. No measured amount of thyroid tissue always to be exactly proper can possibly be left behind after subtotal thyroidectomy; if too much is taken out, hypothyroidism will probably

develop, and if too little, recurrence of the clinical picture is likely. To an internist the line between the production of artificial myxedema and failure to check hyperthyroidism is a fine one; the wonder is that satisfactory results from surgery are obtained as frequently as they are.

Rienhoff¹⁴ made biopsies of thyroid glands from patients operated on for thyrotoxicosis at intervals after operation. His studies suggested that subtotal thyroidectomy did not diminish histologic evidence of thyroid hyperplasia up to several months after operation. Branch²⁹ has had opportunity to examine the thyroid remnant in 1 case eight weeks after subtotal thyroidectomy for thyrotoxicosis. His findings confirm Rienhoff's. He reports that the appearance of the two sections were much alike: in the one was evidence of a hyperplastic overactive gland which came from a patient known to have an elevated metabolic rate; in the other was evidence of a hyperplastic overactive gland in a thyroid remnant weighing only a few grams, also known to come from the same patient, now with normal metabolic rate. Such evidence suggests, therefore, that the thyroid remnant after operation continues

TABLE 5.—Cases with Recurrent Thyrotoxicosis

Case No.	Treatment of Hyperthyroidism	Date of Present Note	Comment
2	Subtotal thyroidectomy	8 years later	Developed recurrence three years after first operation; had second operation and developed hypothyroidism; death eight years after first operation
19	Subtotal thyroidectomy	24 years later	Developed recurrence two years after first operation and a third recurrence three years after the second; both recurrences were treated by surgery; since last operation has enjoyed good health
31	Subtotal thyroidectomy	19 years later	Developed recurrence seven years after first operation and a third recurrence two years after the second; both recurrences were treated by surgery; since last operation believes that she has had waves of minor recurrences controlled by iodine and rest; has gained 30 Kg. since first operation

to be stimulated by whatever the fundamental cause of the disease may be and does its best to produce thyroxine as fast as it can until possibly Barker's "burning out" process becomes manifest or until one of Plummer's cycles of spontaneous remission occurs.

Rienhoff's findings coupled with other of his studies concerning the effect of thyroid on the microscopic appearance of the thyroid gland led him to resurrect an old idea: the use of thyroid in the treatment of hyperthyroidism. Fifty years ago this was a fairly popular form of therapy. At the annual meeting of the Massachusetts Medical Society in 1895, J. J. Putnam³⁰ spoke about modern views on the nature of toxic diffuse goiter. In discussing treatment he announced it was known that occasionally the use of thyroid led to an improvement in the condition, and this was indeed a blow to those who thought that the disease was related to excessive thyroid secretion.

Owen³¹ was one of the early proponents of thyroid feeding in the treatment of thyrotoxicosis. In 1893 he reported a most striking case: A man with hyperthyroidism was advised to eat each day one fourth lobe of freshly minced sheep's thyroid flavored with a little salt and vinegar. Once, by mistake, for two days

31. Owen, D.: Thyroid Feeding in Exophthalmic Goitre. *Brit. M. J.* 2: 1211 (Dec. 2) 1893.

the man's wife gave him one-fourth pound of this mixture to eat and this promptly induced what was described as a violent dyspepsia. A few days later the proper dosage was resumed and the patient was much gratified; for he steadily improved and finally grew well. Thus he continued with the medicine, finding that if he did not take it he would relapse, whereas so long as he used it he stayed in good trim.

A little over a year later Owen³² made an interesting confession. A friend of his had read the first report and pointed out that the thyroid gland of a sheep ordinarily weighs 80 grains (5 Gm.), so that a quarter pound of sheep's thyroid would mean twenty whole glands a day and this appeared an incredible quantity for a man to ingest. Owen, therefore, examined what his patient was eating and discovered he had been taking thymus, an excusable mistake, in Owen's opinion, since the butchers of the day were familiar with the "neck-berg" and the "heart-berg" of young sheep (the cervical and thoracic thymus) but often were ignorant of the existence of the thyroid gland.

At about the same time Mikulicz³³ in Germany and Cunningham³⁴ in America reported that in the treatment of toxic diffuse goiter the use of minced thymus

in the treatment of toxic diffuse goiter until H. S. Plummer reclaimed it, one feels that some modern investigator might do well to repeat Owen's work.

This, however, is by the way. For Rienhoff determined to use thyroid in the treatment of hyperthyroidism for an entirely different reason. He concluded

Fig. 3.—A type of hyperplastic goiter resulting in myxedema. The photograph is from a section of thyroid gland removed when the patient's metabolic rate was + 69. There is evidence of hyperplasia, but also there is considerable fibrosis and lymphocytic infiltration. Nineteen years later the patient's metabolic rate was — 37 and she had clinical myxedema. (Courtesy of Dr. Shields Warren.)

might be followed by results that were both surprising and pleasing. When one recalls how iodine first happened to be used by accident and was then discarded

that the amount of thyroid secretion in the blood stream at any time determines the activity of the thyroid parenchyma and hence that cellular activity would take place at a minimum rate when there was an abundance of circulating secretion. With this thought in mind he first began to give thyroid to patients with hyperthyroidism after operation, thereby hoping to induce atrophy in the stump of tissue remaining and thus to do away with recurrences. So far he has noticed no detrimental effects from using thyroid in this fashion, and indeed his results appear promising. He has treated a few cases without operation in the same way and with equally promising results. De Courcy³⁵ has followed this lead and also reports success. It may be that by reviving an obsolete method we are on the threshold of developing a means to lessen post-therapeutic recurrences of thyrotoxicosis. To accomplish this would be a distinct advance in treatment.

THE PERIODIC EXAMINATION OF PATIENTS WITH TOXIC GOITER

One feature of thyrotoxicosis is very clear: patients with it must be carefully followed. Their periodic examination is fully as important as is the periodic examination of the diabetic, the cardiac or the syphilitic patient. Their weight must be watched, their level of metabolism must be surveyed at intervals, and unexpected complications must be guarded against as long as they live.

Table 6 reports the results in 3 patients who have been particularly cooperative in reporting whenever they were asked to; their records show apparent minor fluctuations in thyroid activity that might have been overlooked had they not been searched for. Patients 3 and 25 at one time appeared to be on the way to develop postoperative hypothyroidism. Whether this ever would have been at all significant is uncertain, because both took thyroid for a short time. Now, as the distance

from operation lengthens, their metabolic rates appear stabilized. Patient 20 appeared to be headed in the direction of a recurrence. When her metabolic rate was found to be +17 she felt nervous and out of sorts. She took Lugol's solution until the rate fell to +10 and she felt better. The iodine was then discontinued, but a few weeks later the metabolic rate had risen to +17 and subjectively she felt as she did before. Since then she has been taking iodine intermittently and her metabolic rate appears to be falling. It is difficult to feel at all sure that such minor changes mean anything; they are reported, however, to illustrate part of the interest that the reexamination of patients with thyrotoxicosis affords any one with clinical curiosity.

LESS COMMON SEQUELAE OF TOXIC GOITER

The remaining 3 patients each presented certain atypical features of thyrotoxicosis which fit in no grouping and must be considered individually:

Patient 6 was first seen when she was 46 years old. A few years later she developed diabetes and, on top of this, thyrotoxicosis when she was 59. Subtotal thyroidectomy was performed and now at 72 she has a basal metabolic rate of +11, so that from the point of view of thyrotoxicosis she is well.

She is unwilling to pay any serious attention to her diabetes, which still exists. It is impossible to judge what effect, if any, the thyroid operation has played in relation to her other disease.

Patient 7 was first examined when she was 44 years old, a thin woman, hard working and seemingly an even tempered, well balanced individual. She was examined at yearly intervals for the following eight years. During the ninth she developed manifestations of thyrotoxicosis, which were treated by sub-

Fig. 4.—Immediate effect on the thyroid gland of thyrotoxicosis treated by surgery. Section of gland removed at operation reduced from a photomicrograph with a magnification of 70. The gland is tissue removed weighed 54 Gm. The gland is epithelial hyperplasia with the formation of papillary projections and slight lymphocytic infiltration.

total thyroidectomy. She recovered satisfactorily and appeared to be well for a year. Then suddenly she developed a psychosis of the manic-depressive type and for the last two years has required institutional care.

A great deal has been written concerning this sort of occurrence, which unfortunately is not rare. The

upshot of opinion by such psychiatrists as Katzenelbogen and Luton,³⁶ Dunlap and Moersch³⁷ and Rulison, White and Stalker³⁸ is that no particular type of psychosis is specifically associated with thyrotoxicosis. In certain instances hyperthyroidism may appear to play a part as an aggravating or precipitating factor

Fig. 5.—Section of the same gland as shown in figure 4 obtained at necropsy eight weeks later. The remnant weighed only a few grams. It is diffusely hyperplastic. There is epithelial hyperplasia with the formation of papillary projections, and moderate lymphocytic infiltration with formation of secondary follicles. On the whole, the appearance of the two sections is much alike. (Courtesy of Dr. C. F. Branch.)

in mental disease but, on the other hand, it may not. One is left with the impression that whatever relationship there may be between thyrotoxicosis and psychiatry is still undetermined.

Patient 15 developed thyrotoxicosis at about the time of the menopause seven years ago, and ever since, despite subtotal thyroidectomy, has had a persistently elevated basal metabolic rate with a tendency to progressive exophthalmos.

Cases of this sort have perplexed many people. Lahey,³⁹ who has continued firmly to advocate the surgical treatment of thyrotoxicosis, believes that the postoperative continuance of hyperthyroidism indicates a left behind segment of hyperfunctioning gland. In such cases, he claims, the administration of iodine is unlikely to be of use, while the removal of a large portion of the segment is often needed to bring about a satisfactory result. Means, Hertz and Williams⁴⁰ have described what they term Graves' disease with dissociation of thyrotoxicosis and ophthalmopathy. They believe that there are cases in which eye manifestations are independent of the thyroid and that in such instances operation on the thyroid may be not indicated while full iodination is. No doubt between these two extremes are borderline cases in which expert judgment in choice of treatment is imperative and decision is

difficult. Cattell and Morgan⁴¹ have advised a sensible middle course in doubtful cases. They assume that persistence of hyperthyroidism after operation is due to combinations of whatever factors outside the thyroid were responsible for the original difficulty, and they advise further surgery only for those who do not improve under medical treatment, seeming reluctant to advise reoperation until it becomes clearly indicated.

CHANGING VIEWS ON THE TREATMENT OF TOXIC GOITER

The literature on toxic goiter has a cyclic character which is most interesting. When thyrotoxicosis first became recognized, the thyroid gland was considered chiefly at fault and efforts were made to control its hyperactivity mechanically. As experience grew, an increasing number of investigators became convinced that thyroid hyperactivity was but a link in the disease, and, as knowledge of endocrinology advanced, the part that the thyrotropic hormone of the anterior pituitary played in producing the clinical picture of thyrotoxicosis came to the front. All this has been reflected in ideas on treatment. The experience of the Massachusetts General Hospital⁴² shows that between 1919 and 1921 half the cases were treated by nonsurgical methods. Between 1932 and 1935 surgery was employed in almost every case. In 1942 half surgical and half nonsurgical procedures were employed, the nonsurgical cases including the special ophthalmopathic type in which Means, Hertz and Williams believe surgery is contraindicated and a variety of others treated successfully by iodine alone or by radioactive iodine and by x-rays. The recent discovery of thiouracil⁴³ as a depressant of thyroid function will undoubtedly stimulate further efforts at the treatment of thyrotoxicosis by other than surgical means.

Many years ago W. J. Mayo⁴⁴ spoke about the crudity of thyroidectomy and expressed the belief that when toxic goiter was better understood a less destructive method of treatment would come about. Little by little we are approaching its development.

SUMMARY AND CONCLUSIONS

Through an attempt to describe thyrotoxicosis as an actual experience in the life cycle of a group of patients observed over a long period of time, certain impressions have resulted which are clearcut and definite. They are by no means novel but serve to reemphasize the peculiar clinical course of a strange pathologic entity of unknown origin.

Hyperthyroidism, whatever its cause, is likely to be a serious affliction. It may affect any one of any age and either sex. It is found more frequently in women than in men. An individual who is tall or short, fat or thin, old or young may develop it, so that to speak of "Graves' constitution" is not altogether reasonable.

The early clinical recognition of hyperthyroidism is difficult. The patient developing it is at first stimulated and may feel unusually well. Only after thyrotoxicosis exists for some time so as to wear a patient down or unless it is notably acute does it make any one feel ill enough to seek medical advice, and by this time usually the diagnosis is easy.

The operative treatment of toxic goiter in expert hands is surprisingly successful. It is a time saving procedure and without great risk. On the whole, it is a more satisfactory form of treatment than any other so far developed. There are two complications following operation, however, which are so frequently encountered as to be a definite hazard: the development of postoperative hypothyroidism or of subsequent recurrences of hyperthyroidism. Both are serious. It is possible that modern methods of treatment and closer cooperation between the surgeon and the pathologist may help to avoid both of these complications in future.

The ultimate result of the surgical treatment of thyrotoxicosis is uncertain. In two completed cases reported here the thyroid gland did not show evidence of regeneration but was atrophic. More information on the entire course of toxic goiter is needed.

The patient with toxic goiter must be reexamined periodically as long as he lives. This is important because the disease naturally has a wavelike character and is chronic. Through careful periodic reexamination complications of toxic goiter may be recognized early, treated promptly, and the life of patients with it may be made more secure. Operative treatment interrupts a vicious circle through an attack on hyperactivity of the thyroid gland. It does not reach the fundamental cause of the disorder and thus is not a curative procedure.

In 1939 attention was called to 2 patients whose arterial blood pressure exceeded normal limits in the course of treatment with desoxycorticosterone esters for Addison's disease.¹ Since that time these observations have been confirmed and extended.² Studies in animals have also revealed an elevation of blood pressure following the administration of desoxycorti-

costerone esters.³ Recently Selye and his co-workers have reported the appearance of vascular lesions in chicks, rats, dogs and other animals following the sustained use of this drug.⁴

In these reports concerning the effect of desoxycorticosterone, it has not been apparent whether the observed increase in blood pressure is due to salt and water retention or to some other unexplained action of the hormone. In order to clarify this problem, it seemed desirable to study the effects of desoxycorticosterone acetate⁵ and of sodium chloride on the blood pressure, blood volume and sodium concentration of the blood in comparable groups of patients with Addison's disease. In addition, it seemed of importance to determine the action of desoxycorticosterone acetate and of sodium chloride in a group of patients without adrenal disease and without an underlying disturbance of electrolyte and water metabolism.

I. EFFECT OF SODIUM CHLORIDE AND DESOXYCORTICOSTERONE ACETATE IN ADDISON'S DISEASE

Clinical Material and Methods.—Observations are reported on a series of 15 patients treated with sodium chloride alone and a group of 24 cases treated with desoxycorticosterone acetate with or without additional salt. Included in the second series are 7 patients who, following treatment with sodium chloride alone, were later treated with desoxycorticosterone acetate and are therefore listed in both groups.

In all cases the diagnosis of hypoadrenalism was established in the wards of the Presbyterian Hospital clinically as well as chemically by a decrease in the sodium concentration of the blood serum during an Addisonian crisis or as a result of the withdrawal of salt from the diet. With rare exceptions, all patients were subsequently examined in the outpatient department at intervals of three months or less. The blood pressure was recorded under similar conditions on each visit to the outpatient department by one of a small group of observers. When abnormal values were found, repeated readings were made for confirmation.

Sodium chloride was given in almost all instances in the form of enteric coated tablets, but a few patients, particularly in the earlier years of treatment, took their salt either in capsule form or in drinking water. The parenteral administration of salt was resorted to in the occasional intercurrent crises. The desoxycorticosterone acetate was given subcutaneously in daily injections except to 2 patients, to whom it was administered every other day. Pellets were later implanted subcutaneously in 6 patients, 2 of whom were subsequently returned to the injection form of therapy.

Plasma volumes were determined after twenty minutes of recumbence with the blue dye T. 1824 and calculated from the optical density of a serum sample drawn ten minutes after injection of the dye. The

optical density was measured with the photoelectric colorimeter, the results being compared with the estimated normal values based on square meters of body surface area.⁶ Total blood volumes were calculated from the plasma volume directly by the hematocrit. Sodium was determined in the blood serum directly⁷ or, at times, in the absence of nitrogen retention, indirectly by the summation of the carbon dioxide content expressed as milliequivalents per liter and the chlorine concentration of the serum expressed as milliequivalents per liter plus 10.⁸ Cold pressor tests were carried out according to the method described by Hines and Brown.⁹

RESULTS

Treatment with Salt Alone.—In this group of 15 patients (table 1) there were 11 men and 4 women, with a mean age of 37 years (standard deviation 6.7). The average period of treatment with salt alone was more than three years in this series. All the members of this group were maintained in electrolyte balance on daily oral doses of sodium chloride in excess of that in the diet. No significant hypertension developed

Effect of desoxycorticosterone acetate on the blood pressure of 3 patients without adrenal disease.

in any of these patients. At no time did the recorded diastolic pressure exceed 90 mm. of mercury. In only 2 patients were systolic values observed above 140 mm. of mercury and then on only one and two readings respectively over a period in which many lower values were recorded. The plasma and total blood volumes were within accepted normal limits in the 3 patients of this series on whom measurements were made. These determinations were made after many months of sustained salt therapy and when serum sodium concentrations were normal. The cold pressor test was carried out in 6 of this salt treated group at the same time. The results were negative in 3 patients, equivocal in 1 and positive in 2.

Treatment with Desoxycorticosterone Acetate With or Without Addition of Salt.—In the group of 24 patients with Addison's disease receiving desoxycorticosterone acetate (table 2) there were 17 males and 7 females, having a mean age of 35 years (standard deviation 10.8). All but 5 were followed for more than one year, the average period of observation being two years. In this series repeated blood pressure

Excluding these 4, there remained 8 patients who gave no history and presented no signs or symptoms to suggest previous or coincidental cardiac, vascular or renal disease. The average age of these patients, in whom repeated blood pressure levels exceeding 140/90 developed in the course of treatment with desoxycorticosterone acetate, was 38 years (standard deviation 6.8). Six of the group were males. The administra-

readings in excess of 140/90 were observed in 12 patients, an additional patient (Ku) having a level of 140/95 at the time of her last visit only. Of these 12 patients, 1 (Deu) had definite antecedent hypertension, another (To) had a history suggestive of angina pectoris before therapy, a third (Wh) came to autopsy, at which time pronounced renal arteriolar sclerosis was found as well as Addison's disease, and a fourth (Ha) was known to have had a labile systolic pressure reaching a maximum of 152 mm. of mercury while a high school student and before the development of hypoadrenalism.

tion of extra sodium chloride was not a constant factor, as 3 received no more salt than that contained in their regular diet. Hypertension developed at different lengths of time after the start of desoxycorticosterone acetate therapy, but the time of its appearance could be measured in weeks or months rather than in days. In 2 instances it appeared within one month, in another not until seven months, and in the remainder the time of onset fell between these intervals. Of particular interest was 1 patient (Fi) whose blood pressure at no time exceeded 118/76 for one year during which his disease was controlled by sodium chloride alone, but

who then developed hypertension within two months after starting desoxycorticosterone acetate therapy without additional salt.

In only 1 patient (Ga) was the elevated blood pressure transient. The remainder continued to show a hypertension while under treatment, except in instances in which the dose of desoxycorticosterone acetate was reduced either with or without concomitant decrease in serum sodium concentration to abnormally low levels. At no time, however, did the hypertension persist when

abnormal cardiovascular signs, in contrast to the rapid cardiac dilatation and failure which may develop when excessive doses of desoxycorticosterone acetate and salt are given in the treatment of an Addisonian crisis. In the latter patients hypertension does not appear.

Cold pressor tests were positive in 3 of 6 patients who did not develop hypertension after prolonged treatment with desoxycorticosterone acetate. In 5 of the group who exhibited abnormal increases in blood pressure, the cold pressor test was positive in 3, equivocal

the sodium concentration fell below 133 milliequivalents per liter. On the other hand, elevation of the sodium level above the normal of 141 milliequivalents per liter was not a factor in the development of hypertension. In addition, blood pressure levels bore no relationship to the rare appearance of minimal peripheral edema resulting from the administration of desoxycorticosterone acetate. In 4 patients who developed hypertension on desoxycorticosterone acetate, the plasma and total blood volumes were within accepted normal limits, determinations being made at a time when the blood pressure was significantly elevated and the serum sodium concentration was normal. Repeated examinations of the urine and also of the retinal vessels revealed no abnormalities. The hypertension has not, up to the present time, been accompanied by symptoms or

in 1 and negative in 1. All of the cold pressor tests were carried out at a time when the serum sodium concentration was normal.

II. EFFECT OF SALT AND DESOXYCORTICOSTERONE ON PATIENTS WITHOUT ADRENAL DISEASE

The following study was undertaken in order to determine if the effects of desoxycorticosterone acetate on the blood pressure of patients with Addison's disease could be reproduced in individuals without disease of the adrenal glands.

Clinical Material and Methods.—Observations were made on 3 young males without hypertension and without a history of cardiac, renal or adrenal disease. All were patients in the First Medical Service (Research Division) of the Goldwater Memorial Hospital, 2 (Be

and Va) with severe rheumatoid arthritis of the Marie-Stümpell type and 1 (Ch) with mild bronchial asthma. At the start of the experiment 2 showed mild albuminuria without evidence of disturbed renal function.

The study was divided into four periods: (1) a two week control period, (2) a two week period of high salt intake (10 to 20 Gm. daily in the form of enteric coated sodium chloride tablets), (3) seven weeks during which each patient received 10 mg. of desoxycorticosterone acetate daily subcutaneously plus varying amounts of salt (0 to 10 Gm. of enteric coated sodium chloride tablets) and (4) a final period of three weeks immediately following the withdrawal of desoxycorticosterone acetate and extra salt.

During the study these patients were afebrile and the extent of their daily activity about the wards did not vary. They ate the regular ward diet and were weighed at a fixed hour at least every other day. Daily records of fluid intake and output were kept. Throughout the period of observation the blood pressure was recorded twice a day. Each recording was the average of five readings, taken in almost all instances by one of two observers. It was ascertained at the start of the experiment that there was no significant difference in pressure between the two arms.

In addition to these measurements, certain other data were obtained at intervals during the study and are recorded in table 3. Heart size was reported as the cardiothoracic ratio. Plasma volume determinations were made as described but with the optical density measured by the Koenig-Martens visual spectrophotometer.¹⁰ The circulation times were measured with a 20 per cent solution of sodium dehydrocholate (3 cc. intravenously). Only 1 of the 3 (Va) had a positive cold pressor test⁹ as determined at the start of the experiment.

RESULTS

Blood pressure readings on all 3 patients during the four periods of the study are shown together in the accompanying chart. In both the control period and the period of salt administration without desoxycorticosterone acetate no significant change in blood pressure levels or body weight was noted. After about two weeks on desoxycorticosterone acetate all 3 patients showed a progressive elevation of blood pressure, 2 gaining a small amount of weight. Only 1 subject (Va) developed symptoms, complaining of severe headaches during the last few weeks on desoxycorticosterone acetate, with the appearance of a subconjunctival hemorrhage and a rise in pressure to 160/108 during the final week. In the final period following the discontinuance of desoxycorticosterone acetate and salt administration, blood pressures returned rapidly to control levels and each of the 3 patients lost a few pounds of weight.

One patient (Va) developed minimal ankle edema during the period of salt administration, and this increased during the first week of salt and desoxycorticosterone acetate therapy, so that sodium chloride tablets were discontinued. This was followed by almost complete resorption of the edema. The second patient (Be) had minimal periorbital and ankle edema during the first week on desoxycorticosterone acetate, but this disappeared completely when the dosage of salt tablets was reduced from 10 to 5 Gm. daily. At the time the

edema appeared, neither patient had gained significant weight or showed any accompanying urinary changes or evidence of cardiac decompensation as judged by symptoms, vital capacity and venous pressure measurements. The third patient (Ch) gained 6 pounds (2.7 Kg.) without apparent edema in the first week on desoxycorticosterone acetate, but was able to continue 10 Gm. of added salt a day until the final period without further gain.

No significant changes in the electrocardiogram were observed. In all 3 patients there was a small increase in the cardiothoracic ratio and some reduction in vital capacity. Two of the 3 patients showed slight increases in venous pressure, which, however, did not exceed normal limits. No consistent alteration in plasma volume resulted from desoxycorticosterone acetate therapy. Thus, 1 subject showed no significant change in plasma volume and a second had a rise of 800 cc. at the end of the desoxycorticosterone acetate period. The plasma volume in the third patient increased only 230 cc. during the period of desoxycorticosterone acetate therapy. His plasma volume subsequently rose another 400 cc. three weeks after his blood pressure had returned to the control level following the discontinuation of desoxycorticosterone acetate.

The unexplained albuminuria noted in 1 patient (Be) increased during the last two weeks of desoxycorticosterone acetate therapy but decreased during the final period. The mild albuminuria found at the start of the experiment in a second subject (Ch) cleared completely during the course of the experiment. Just before the end of the last period, after desoxycorticosterone acetate and salt had been withdrawn, 1 subject (Va) developed pain in the left flank and gross hematuria; a left ureteral stone was later demonstrated. During desoxycorticosterone acetate therapy the ability to excrete phenolsulfonphthalein was not reduced in any of these patients.

COMMENT

The development of hypertension in 8¹¹ of 24 patients with Addison's disease when under treatment with desoxycorticosterone acetate confirms earlier observations suggesting that this hormone may have an effect on the blood pressure. Since this pressor effect of desoxycorticosterone acetate has furthermore been demonstrated in 3 subjects without adrenal disease, it cannot be considered a phenomenon associated solely with hypoadrenalism.

The mechanism of this elevation in blood pressure is not clear, but as yet there is no evidence in the group studied that it leads to progressive arteriolar changes such as may occur in hypertensive vascular disease or have been reported in animals by Selye.⁴

From the present study, the development of hypertension cannot be ascribed to the restoration of the electrolyte and fluid balance to normal in patients with previous adrenal insufficiency. This restoration occurs promptly when acute hypoadrenalism is treated with adequate salt and replacement therapy, whereas the hypertension observed after treatment with desoxycorticosterone acetate requires weeks or months to become apparent. Also no abnormal increase in blood pressure appeared in the group of Addisonian patients treated with salt alone over long periods of time, despite the fact that all those patients in whom it was measured

10. Noble, R. P., and Gregersen, M. I., to be published. Dr. Noble gave assistance in these determinations.

11. Four additional patients developing hypertension were excluded because of possible preceding cardiovascular disease.

maintained a normal serum electrolyte pattern and a normal blood volume.

It is apparent that the elevation of blood pressure cannot be correlated with excessive retention of salt or water in the circulating blood or with the development of edema. In the group of addisonian patients treated with desoxycorticosterone acetate the appearance of hypertension was not associated with abnormally high concentrations of the sodium ion in the blood serum. Furthermore, the circulating plasma volume lay within normal limits in 4 desoxycorticosterone acetate treated patients with Addison's disease at a time when their blood pressures were significantly elevated. In addition, the rise in blood pressure following the administration of desoxycorticosterone acetate in the group without adrenal disease was not consistently associated with an abnormal increase in blood volume. There was no correlation between the appearance of hypertension and the excessive accumulation of interstitial fluid in the addisonian patients treated with desoxycorticosterone acetate.

The possibility exists that unrelated hypertension may have been present in all of the group of addisonian patients who developed abnormal elevation of blood pressure during treatment with desoxycorticosterone acetate. This, however, seems improbable because of the fact that none of the patients in the comparable group treated with salt alone developed hypertension, although they were maintained in normal electrolyte and water balance. Furthermore, none of the patients who developed hypertension with desoxycorticosterone acetate therapy had elevation of blood pressure while on earlier treatment with salt alone.

There was no correlation between the appearance of hypertension and a positive cold pressor test in either the addisonian or the control group in the present study. It would therefore appear unlikely that a labile vascular system, as manifested by a positive cold pressor test, is the determinant for the development of hypertension with desoxycorticosterone acetate.

The mechanism of the elevated blood pressure following the prolonged administration of desoxycorticosterone acetate remains obscure. It does not appear to be referable either to abnormalities in the retention of salt and water or to underlying hypertensive disease. It seems probable that desoxycorticosterone acetate acts directly or indirectly on the peripheral vascular system.

CONCLUSIONS

1. The appearance of hypertension in a number of patients with Addison's disease in the course of prolonged treatment with desoxycorticosterone acetate has been confirmed. No similar increase in blood pressure followed the prolonged administration of salt alone.

2. In 3 patients without adrenal disease, a gradual increase in blood pressure has been observed in association with the administration of desoxycorticosterone acetate. The blood pressure in these patients returned to control levels within two weeks following the withdrawal of desoxycorticosterone acetate.

3. The increase in blood pressure cannot be correlated with abnormal retention of the sodium ion or with an increase in circulating blood volume.

4. The increase in blood pressure observed is not apparently dependent on an abnormally labile peripheral vascular system as measured by the cold pressor test.

Clinical Notes, Suggestions and New Instruments

SPONTANEOUS RUPTURE OF AORTA IN SYPHILITIC AORTITIS WITH ANEURYSM

DOUGLAS SYMMERS, M.D., NEW YORK
General Director of Laboratories, Department of Hospitals,
City of New York

That spontaneous rupture of the aorta in syphilitic aortitis without aneurysm is a rare event is indicated by the fact that it was encountered only twice in 73,607 necropsies performed in the thirteen general hospitals of the twenty-two hospitals of the Department of Hospitals of the city of New York. The literature on the subject seems to be limited to the statement that "a syphilitic aorta never ruptures unless it has given rise to aneurysm."¹ The 2 cases referred to are recorded in this report.

REPORT OF CASES

CASE 1.—History.—A man aged 40, Italian, a rubbish collector, was admitted to Bellevue Hospital in a moribund state and died twenty-five minutes later. It was said that he had been well until two hours before admission, when he complained of faintness, substernal pain and shortness of breath. On admission he was cyanosed, the hands were cold, no radial pulses could be felt, breathing was labored and the veins of the neck were engorged. The heart sounds were weak and distant. While in the hospital the patient vomited on frequent occasions. The condition of the patient's blood pressure before he entered the hospital was not learned.

Necropsy.—The body was well developed and well nourished, 162 cm. in height and weighed about 77 Kg. There was no external edema. The precordial area was greatly enlarged, the lungs pushed aside by the bulging pericardial sac. When the pericardium was opened, dark red fluid blood escaped. In the dependent part of the sac there was a large dark red jelly-like clot. The heart was contracted, and very little blood was found in it. The wall of the left ventricle was moderately thickened. The endocardium was well preserved with the exception of the posterior and right anterior aortic cusps, which were thickened at the margins adjoining the commissures. The commissures were widely separated. Lying beneath and elevating them were several hyaline plaques, which encircled the aorta immediately above the valves. Some of these plaques were finely wrinkled. Just above the posterior aortic cusp there was an irregularly lacerated aperture measuring 6 mm. in length and 4 mm. in breadth. The edges were serrated, reddish and infiltrated with blood. The remainder of the aorta appeared to be well preserved. The orifice of the right coronary artery was stenosed; that of the left was apparently normal.

Microscopic Examination.—Aorta: The adventitia was greatly thickened, owing to the presence of patches of connective tissue which were more or less well supplied with poorly nucleated fibroblasts and areas in which collagenous fibers were hyalinized. Scattered through the adventitia were large collections of lymphocytes and in other places smaller collections composed almost exclusively of plasma cells. The vasa vasorum were thickened and the lumens compressed. Some of them were surrounded by mantles of lymphocytes and plasma cells. Their walls were made up of loosely arranged fibromuscular tissue. In the media of the aorta the muscle was almost completely replaced by fibrous tissue. Those fibers that remained were granular and almost completely bereft of nuclei. The elastic tissue was relatively plentiful and the individual fibers were thickened, some of them split or frayed at the ends, others fragmented. Scattered through the media were numbers of small hyalinized scars arranged around the lumens of small vessels. Near the point of perforation the media showed a large hyalinized scar in which practically no nuclei were visible.

From the Laboratories of Pathology, Bellevue and Goldwater Memorial Hospitals.

1. Criteria Committee: Nomenclature and Criteria for Diagnosis of Diseases of the Heart, ed. 4, New York, New York Heart Association, 1939, pp. 35 and 226.

The intima in places was elevated and made up of a few fibroblasts lying close to the media. The connective tissue in the intima was anuclear, hyalinized and, in places, granular and necrotic.

Microscopic examination of the remaining organs, including the kidneys, showed nothing of importance in the present connection.

CASE 2.—History.—A man aged 79, Italian, who died within a period of about five minutes while bathing his face, had been under observation for five weeks because of signs of nephrosclerosis and so-called hypertensive heart disease. While in the hospital the blood pressure varied from 143/100 to 210/140. The Wassermann reaction was negative.

Necropsy.—The precordial area was enormous and was bluish red. The pericardium was distended by clotted blood in which the contracted heart was completely buried. The heart, with the attached aorta, weighed 760 Gm. The left ventricle measured 2.5 cm. in thickness just below the level of the posterior mitral cusp. When the heart was opened the endocardium was found to be smooth and glistening. The ascending aorta was dilated toward the right, where it was thinned. The aortic cusps were thin and pliable. The inner surface of the aorta from commencement to bifurcation, but particularly in the ascending portion, was light grayish and showed numerous firm elevated pearly plaques, some of which were wrinkled. On the left side of the aorta about 5 cm. above the sinuses of Valsalva was an oblique linear perforation. It measured 4 cm. in length and its edges were irregular and freshly hemorrhagic. The immediately surrounding adventitia was infiltrated with blood.

The kidneys were about normal in size. The capsules stripped without difficulty, leaving an irregularly scarred surface. Between the areas of scarring the surface was finely granular. On section the cortices were narrow and retracted, especially at the extreme periphery.

Microscopic Examination.—Aorta: The adventitia was moderately thickened and, in places, sclerotic and hyalinized. Scattered through it were collections of lymphocytes with a fairly liberal admixture of plasma cells. In some instances the vasa vasorum showed only slight thickening of the fibromuscular walls, occasionally accompanied by reduplication of the lining endothelium. In other instances the vasa vasorum were decidedly thickened, owing to hyperplasia of the muscular coat and reduplication of the endothelial lining, producing either eccentric or concentric and almost complete occlusion of the lumens. A few of the vasa vasorum were surrounded by collections of lymphocytes and a sprinkling of plasma cells. The media of the aorta was thinned and partly replaced by hyalinized connective tissue, which in places was distributed in such fashion that intima and adventitia were separated by a thin layer of compressed and atrophied muscle and remnants of elastic tissue. In addition, the media was replaced at intervals by scar tissue distributed around small blood vessels with thin walls. In specially stained sections the elastic tissue seemed to be greatly reduced in quantity and the individual fibers were sometimes thinned, at other times thickened. In numerous instances they had lost their wavy contours. Some of them were fragmented; others were reduced to shreds or clumps of granular debris. The intima was thrown into moundlike formations composed of poorly cellular, frequently sclerotic and sometimes hyalinized connective tissue.

Liver: In the liver were numerous focal collections of lymphocytes, many of which were associated with an admixture of a few fibroblasts and plasma cells. Some of these focal collections, which lay among and displaced the parenchyma cells, were centrally necrotic (miliary gummas).

Kidneys: The kidneys were congested, especially in the cortex, where the vessels in places were distended. Immediately beneath the capsule were numerous wedge-shaped areas composed of connective tissue supporting a few tubules in different stages of compression and dilatation, injected capillary vessels, glomeruli in various stages of fibrosis, some of them completely hyalinized, and lymphocytes arranged diffusely or densely in patches. Deeper in the cortex many of the arterioles were sclerotic and sometimes hyalinized. The arteries were similarly changed. The glomeruli were congested. In some of them

the capsular space contained coagulated granular material. In other instances the glomeruli showed productive capsular changes passing through various gradations to complete sclerosis and hyalinization. The convoluted tubules were moderately dilated, their lining epithelium granular and their lumens containing debris.

COMMENT

When syphilitic aortitis first attracted attention in this country it was observed that the microscopic changes were usually characterized by signs of activity.² As a rule there was nothing vague or indeterminate in the histologic picture. Gradually a period of transition set in and the tissues began to show modifications in the direction of inactivity. For some years past it has not been common in my experience to encounter syphilitic aortitis of other than the inactive or "burned out" variety. Inactivity appears to be brought about irrespective of treatment because inquiry almost invariably reveals that treatment was either neglected or inadequate.

In syphilitic aortitis the process of vascularization extends from the adventitia well into the media, replacing both muscle and elastic fibers, ending in the formation of scars. The intimal reaction, which consists of overgrowth of the sub-endothelial fibroblasts progressing to connective tissue formation followed by hyalinization, is commonly interpreted as a compensatory process. However this may be, the fact remains that the vessel wall is comparatively well fortified, although frequently injured in such fashion as to permit true aneurysmal dilatation and spontaneous rupture. In the 2 cases here recorded the changes in the aortic wall seem to me to have attained a degree of severity beyond that of the customary destruction and replacement of tissue, notably in the media. In the first case the elastic fibers, although plentiful, were thickened and shortened and had lost their wavy outlines, indicating, no doubt, loss of elasticity, and the muscle substance was almost completely replaced by fibrous tissue. In the other case the elastic fibers were reduced in numbers and thinned, and the inter-muscular connective tissues were sclerotic and hyalinized, sometimes to an extreme degree. In other words, the histologic changes in both cases showed injury of the vessel wall to an extent which seems to justify the appellation of a "burned out" process. It is true that most "burned out" syphilitic aortas do not rupture spontaneously, and doubtless some additional factor or factors are operative in those circumstances in which spontaneous rupture occurs without aneurysm. In case 1 of this report there was no obtainable record of the condition of the patient's blood pressure previous to admission to the hospital. Nevertheless, because of thickening of two of the aortic cusps and wide separation of the commissures it may be safely assumed that the patient suffered from some degree of aortic regurgitation attended with elevation of systolic blood pressure. In the second case there seems to be no doubt that rupture of the aorta was due to sudden increase in a degree of blood pressure already considerably above that of the normal.

In those cases of medial necrosis of the aorta in which spontaneous incomplete rupture occurs with the production of so-called dissecting aneurysms, the patients' blood pressure is practically always high and is commonly believed to be the immediate cause of the tear in a weakened vessel wall. It seems reasonable to anticipate that an elevation of blood pressure will be eventually shown to operate in spontaneous rupture of the aorta in uncomplicated syphilitic aortitis. In that section of his book on Human Pathology dealing with the subject of "dissecting aneurysm," Karsner³ states that "the lesion is rare in syphilitic aortitis." From this it may be inferred that "dissecting aneurysm" sometimes follows incomplete rupture of the scarred media of the syphilitic aorta and that an elevation of blood pressure is the immediate cause, as it is in "dissecting aneurysm" associated with medial necrosis of the aorta. Even from the scanty information available, the opinion seems to be justified that the rarity of spontaneous rupture of the aorta in syphilitic aortitis without aneurysm is due to the fact that in pure, uncomplicated syphilitic aortitis the blood pressure is normal or approximately so.

2. Symmers, D., and Wallace, G. H.: *The Etiology of Syphilitic Aortitis*, J. A. M. A., 68: 397 (Feb. 5) 1916.

3. Karsner, H. T.: *Human Pathology*, ed. 6, Philadelphia, J. B. Lippincott Company, 1942, p. 392.

Rottino and Poppiti⁴ have recently shown that thickening, hyalinization and wrinkling of the intima of the aorta closely resembling the intimal changes in syphilitic aortitis sometimes occur in association with medial necrosis and may be followed by spontaneous rupture and the formation of a "dissecting aneurysm." The naked eye appearances of such an aorta are apt to be deceptive, and microscopic examination should be made to exclude syphilitic aortitis.

CONCLUSIONS

Spontaneous rupture of the aorta in syphilitic aortitis without aneurysm occurs but is extremely rare. Rupture is complete, occurs without "dissection" and is rapidly followed by death from hemorrhage into the pericardial sac. An elevation of blood pressure is probably the precipitating factor in the production of the tear in a vessel wall which has already been severely damaged by syphilis.

THE RAPID IDENTIFICATION OF MUCOID HEMOLYTIC STREPTOCOCCI OF POSSIBLE EPIDEMIC ORIGIN

MAJOR ISADORE PILOT
MEDICAL CORPS, ARMY OF THE UNITED STATES

In the search for epidemic strains of hemolytic streptococci, earlier investigations were related to the isolation of mucoid strains of hemolytic streptococci. It was pointed out that mucoid encapsulated streptococci have epidemiologic significance.¹ Milk borne epidemics of sore throat and scarlet fever have yielded consistently mucoid forms of beta hemolytic streptococci (*Streptococcus epidemicus*) if proper mediums and differential methods have been employed.²

To identify these mucoid strains readily a culture medium of ascites fluid added to fresh infusion blood agar has been described.³ As ascites fluid is not always available, the present study was directed to find a simple medium that could be used routinely for the rapid isolation of mucoid strains for grouping and typing.

Various mediums used in army laboratories were tried. Dehydrated brain heart infusion as prepared by Difco with 1.75 per cent agar furnished a satisfactory base for blood agar. Fresh moist plates with 5 per cent human blood inoculated with throat swabs, exudates and slant cultures from various sources gave striking results on both streaked and poured plates. In twelve to twenty-four hours the colonies appear large, mucoid, often aneuboid and confluent, then rapidly flatten to smooth or wrinkled phases. Infusion agar prepared with various peptones including neopeptone failed to bring out the large mucoid growth.

In the spring and fall of 1943 in routine cultures of throat and nasopharynx of 150 individuals, including both normal persons and patients with upper respiratory infections, no mucoid hemolytic streptococci were encountered. A few green mucoid colonies proved to be type III pneumococci, none of the green variant of the alpha hemolytic streptococci prevalent during and immediately after the pandemic influenza of 1917-1918.¹ Throat cultures of patients with sore throat, scarlet fever and rheumatic fever, none of which were related to milk borne infection, frequently yielded predominant numbers of mucoid hemolytic streptococci often in pure culture. As previously observed, these streptococci appear etiologically related and can be readily followed and correlated with clinical course, complications and sequelae, especially with reference to rheumatic manifestations.²

By Lancefield's method of grouping, the mucoid beta hemolytic streptococci uniformly fell into group A. Typing by Griffith's slide agglutination method classified some strains as

type 1, 3 and 14. Many of the mucoid strains were difficult to type clearly by this method and were sent to Dr. M. T. Hamburger, who by the new Wilson-Lancefield capillary precipitin method⁴ typed these strains predominantly as 17 and a few 19 and 30.

Type 17 was largely from scarlet fever patients, types 1, 3 and 14 from throats in early stages of rheumatic fever. Types 1 and 14 produced definite purulent arthritis in young rabbits injected intravenously with 0.1 cc. of twenty-four hour broth cultures.

Of special interest are the recent reports of milk borne outbreaks of sore throat and scarlet fever, now traced to serologically specific types of hemolytic streptococci.⁵ Among these epidemics type 3 accounted for three outbreaks, 2 and 17 for other episodes. These types appear to be sources of epidemic strains, but no mention is made of any mucoid property. However, our past experience with strains from milk borne epidemics of sore throat has emphasized this important characteristic.⁶ The mucoid strains are particularly responsible for the bovine mastitis which is the source of epidemic milk borne septic sore throat and scarlet fever. Experimentally the mucoid strains ascend into the udder by simply smearing the teat and cause a similar mastitis.⁷ This aggressive property of the mucoid strains is further demonstrated by the frequency of their occurrence in otitis media, mastoiditis and meningitis complicating sore throat.⁸

SUMMARY

During periods of high incidence of scarlet fever, sore throat and rheumatic fever many beta hemolytic streptococci may be found in throat cultures. Attention to mucoid forms will simplify the isolation of etiologically related strains.

By the use of brain-heart infusion blood agar, mucoid beta hemolytic streptococci can be isolated readily and then grouped and typed to ascertain their epidemiologic importance.

PALINDROMIC RHEUMATISM

LIEUTENANT COLONEL JAMES C. CAIN
MEDICAL CORPS, ARMY OF THE UNITED STATES

In June 1940 Hench and Rosenberg¹ described a new syndrome called palindromic rheumatism. At that time they described findings in 34 cases. There is much to indicate that this is actually a disease entity. In the army, where one sees so much real and neurogenic arthritis, it is not unusual that an occasional case of palindromic rheumatism should be found. This case is being reported because the condition has only recently been recognized as a disease entity, and it is felt that more cases will be found if the attention of physicians is directed toward this disease.

REPORT OF CASE

History.—A soldier aged 23 from Ohio was admitted to the Station Hospital, Camp Gruber, Oklahoma, with the chief complaint of recurrent attacks of pain and swelling of the wrists and ankles. The soldier had been in the army for one year but was unable to do his required duties because of attacks of joint pain. The attacks were characterized by sudden onset with considerable pain, moderate swelling, mild redness, slight increase in warmth and pronounced disability of

the involved joints. No chills, fever or other symptoms were experienced. An attack often began and reached its height in a period of ten to twenty minutes, but most attacks came on over a period of eight to eleven hours. The first attack occurred at the age of 16 years, and subsequent attacks have occurred approximately once or twice a week. Well over two hundred attacks have been experienced. Practically all joints in the body have been involved, but the attacks have been localized largely to the wrists and ankles. Usually only one joint was involved. Some attacks have lasted only thirty minutes, while others caused distress for as long as two weeks. Attacks have been so severe that they cause him to cry out with pain. No known precipitating causes could be elicited. Attacks were not precipitated by nervousness, worry or changes in weather. He was tested for allergic factors, but none were present. The patient's history and his family's history were entirely negative for rheumatic or allergic manifestations. His father died of tuberculosis, but the patient has been frequently checked by roentgenographic and other methods, and at no time has he been found to have this disease. The family history was entirely noncontributory. Some relief was obtained from heat and slight relief from alternately immersing the involved joint in hot and cold water. Acetylsalicylic acid gave temporary relief. Injections of epinephrine did not alter the pain or swelling. The review of systems revealed that he had only light perception in the left eye, because of an old external strabismus. The right eye was essentially normal. He had occasional left frontal headaches, but they were not severe. The cardiovascular, respiratory, gastrointestinal and genitourinary systems were entirely normal. The patient was quite nervous. He had moderate tendency to worry, was quite irritable and was bothered by insomnia to a mild degree. He felt definitely that his condition was gradually getting worse.

Physical Examination.—The patient appeared essentially normal. He was 68 inches (173 cm.) in height and weighed 132 pounds (60 Kg.). The heart was normal in size, rate and rhythm. The blood pressure was 120/80. The lungs were clear. The liver and spleen were not palpable, and no abdominal masses were present. Approximately seven attacks were experienced while he was in the hospital. One attack was observed to appear and reach its height within a period of ten minutes. The duration of this attack was approximately six hours. The right wrist was noted to become slightly swollen, moderately warm and exquisitely tender during each attack. On one occasion there was periarticular swelling of the lateral flexor surface of the right wrist involving an area of approximately 2.5 cm. in diameter. This area was tender and painful. There was no itching, and it did not appear to be due to angioneurotic edema. Both passive and active movement of an involved joint caused much pain. There was no atrophy of the tissues about the involved joints, and roentgenograms of the wrists and ankles were entirely negative. No skin rashes were present, nor was there any evidence of allergic manifestations noted at any time. No fever or chills were present. Laboratory examinations were all within normal limits. The urine showed a specific gravity of 1.023. No albumin was present, and microscopic examinations were negative. The leukocyte count was 8,200, with 68 per cent polymorphonuclears and 32 lymphocytes. The erythrocyte count was 4,000,000, with 81 per cent hemoglobin. Repeated sedimentation rates were normal, as was the electrocardiogram. Agglutination tests for brucellosis were negative. Uric acid was 2.6 mg., cholesterol 115.2 mg. and calcium 9.9 mg. per hundred cubic centimeters. Unfortunately a determination of fatty acids and total lipoids could not be obtained. Skin and food tests for allergy were negative. No relief was noted from injections of epinephrine.

COMMENT

This case represents a typical picture of palindromic rheumatism as described by Hench and Rosenberg.¹ The characteristic features were multiple afebrile attacks of acute arthritis and periartthritis. There were mild redness, moderate to mild swelling, moderate tenderness and pronounced disability of the joint during an attack. Attacks involved only one joint at a time, and they occurred suddenly and were frequently of short duration, lasting from several hours to fourteen days. No

constitutional reaction was present, and the sedimentation rate and other laboratory findings were normal. The blood cholesterol was slightly lower than normal, being 115.2 mg. per hundred cubic centimeters, but the exact significance of this is not known. Dr. Hench found the fatty acids and total lipoids moderately elevated in his cases, but unfortunately these tests were not performed in this case. Roentgenograms during and between attacks were normal. No evidence of vasomotor instability was noted. A thorough survey revealed no allergic factors.

This represents a typical case of palindromic rheumatism. Perhaps this syndrome occurs more frequently than is generally realized, and as physicians become cognizant of its features it will be diagnosed more often.

CATHETER INCONTINENCE FOLLOWING CYSTOSCOPY

NORVELL BELT, M.D., WASHINGTON, D. C.

Cystoscopy, with indwelling ureteral catheters as its objective, entails some discomfort to the patient when drainage must be established for a period of time. One of the most annoying sequelae is in the female patient, in whom large quantities of urine pass around the catheters through the urethra. The dilemma of continuous confinement on the bed pan or perpetual changing of bedclothes is a serious nursing problem, to say nothing of the dangers to the patient. The possibility of upper respiratory infections is increased by moisture. There is no rest for the wet.

Apparatus for keeping patient dry after cystoscopy

The apparatus described here has solved the problem of keeping the patient dry. It consists in threading a Foley female number 22 French catheter, 5 cc. bag capacity, over the distal ends of the ureteral catheters. A copious supply of surgical lubricant is applied to all catheters. The bag is distended after introduction into the bladder, and the bladder outlet is occluded with gentle traction. To facilitate passage over the ureteral catheters, that portion of the catheter tip including the fenestra is cut off. The protruding ends of the ureteral catheters are threaded in a glass inverted Y tube and brought out on the proper side through cystoscopic nipples and connected with sterile containers. The urine that enters the bladder from around the

ureteral catheters may cause some retention. The Y tube may be disconnected and the bladder drained ad libitum. Usually once a day suffices.

Sulfonamide therapy is contraindicated, owing to the danger of the accumulation of crystals around the foreign body. In a few cases in which these drugs were used, removal of the catheter was difficult because of chemical deposits.

Anatomic differences make this apparatus more practical for the female than the male, although it may be used for either sex. Man is not an amphibious animal, and the comfort, rest and dryness results in a grateful patient and solves a nursing problem.

Special Article

AMERICAN HEALTH RESORTS

TREATMENT OF CONDITIONS AFFECTING THE GENERAL NERVOUS SYSTEM

THE PLACE OF HEALTH RESORT THERAPY

GEORGE B. FLETCHER, M.D.

HOT SPRINGS NATIONAL PARK, ARK.

These special articles on spa therapy and American health resorts were prepared under the direction of the Committee on American Health Resorts. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the committee. These articles may be published later as a Handbook on Health Resorts.

The term health resort may be applied loosely to any place from a "dude ranch" to a well set up spa where facilities are available for therapeutic baths and physical therapy as well as understanding, intelligent medical care and recreational features.

In one category we think of the three R's Rest, Recreation and Recuperation, and in another we think of means of bringing about relief of pain, improvement in muscle tone and coordination whereby a patient may regain, at least in part, that which has been lost.

While climate may be a factor, the most important requirements to be considered are (1) good medical care, (2) adequate facilities, well regulated, for giving the different forms of treatment and (3) a setting which will be conducive to peace of mind in the patient.

There is no place in the setups of spas for the advertising of "miracles," and only facts, unglamorized, should be stated; otherwise there will be the danger of a "racket" developing.

While health resorts do not all have hydrotherapy available, and some resorts, such as those catering to chest diseases, do not need hydrotherapy, the type of patient discussed in this paper will need this service.

An outstanding factor in favor of going to a resort for the "cure" is that a person gets away from worries present at home, meets new people, and, whereas ordinarily he would find too many things to interfere with going to see his doctor, he has nothing else to do but make a business of getting well. He is able to follow a regular schedule without thinking of the office and, seeing others following such a schedule, he does not feel at all out of place. He will follow out his physician's orders, feeling that he is preparing himself to resume his labors in a better physical and mental condition.

Many things may be done with water. We may confine our treatments to underwater or pool baths if these are indicated or, on the other hand, we may go into the other departments where we may receive the tub bath, packs to various parts of the body, sitz baths, salt glows, scotch douches where desired, needle showers, whirlpools, cabinets or massage, and many of these may be combined to bring about results depending on the patient's complaints. For instance, a patient with a lame shoulder may need a douche and hot packs on the shoulder, and one with hemorrhoids or a prostatitis may obtain much comfort from a prolonged sitz bath. It is not unusual for a pool patient, perhaps a "polio" or spastic, to request that he be allowed to take an occasional routine bath as a sort of vacation from the pool.

Lowman,¹ in speaking of pool therapy, states that "it is generally conceded that the medical profession's failure to recognize its value has not only retarded hydrotherapeutic development and use in this country but has caused the adoption of various hydrotherapeutic procedures by unethical cults and quacks." Water, probably the oldest medium of physical treatment, possesses greater possibilities for good in physical rehabilitation than any other modality. Right here it might be said that the United States government, realizing the truthfulness of this statement, is sending here, and probably to other spas, great numbers of soldiers who have developed disabilities from army and navy service. For many years it has been realized that it is easier to perform exercises in the water than under normal atmospheric pressure. This is especially striking in the case of treatment of extremities which have been greatly weakened by paralytic or paretic conditions, so this knowledge has led to the application of underwater treatment to the reeducation of disabled or impaired muscles. Archimedes' law of displacement explains the advantages to be expected by underwater treatments.

The history of the use of water in the treatment of disease, while most interesting, would constitute a complete discussion in itself. Here we are dealing not only with organic disease of the central nervous system but also with the psychoneurotic and other similar mental conditions. The patient who is "just nervous" is depressed, has a feeling of inward tension and is generally unhappy.

A simple classification of the diseases of the central nervous system seen at resorts is as follows:

1. Spastic paralysis.
2. Flaccid paralysis with atrophy.
3. Sensory changes which may accompany either of the foregoing.
4. Peripheral nerve conditions such as neuritis and neuralgia.

Of the functional diseases seen at resorts the following are the most usual:

1. Psychoneurosis.
2. Simple depressions.
3. Involuntary depressions which will not be helped by resort treatment alone.
4. Exhaustion states following unusual stress in business or home life or following a prolonged illness.

Then there will be a certain number of patients with Parkinson's disease or the syndrome following encephalitis, together with a few patients exhibiting a fine tremor such as that found in hyperthyroidism.

It is a well known fact that a body in water will weigh much less than it would outside the water; for instance, a body weighing 132 pounds outside the water will weigh only 6 pounds when submerged, and by using this principle it is easy to see why weakened muscles and joints can perform acts which would be impossible without this buoyancy. The psychologic reaction in a patient who has been bedridden is often dramatic when he finds himself able to move in the water whereas in bed he was "just too heavy." The word "pool" has been associated with swimming so long that one may think only in these terms, and we do know that there is a place for supervised swimming along with the other exercises; but unsupervised swimming might cause harm, owing to the fact that the patient may have to learn to swim over again and in doing so find that the old muscles he formerly used are no longer func-

1. Lowman, C. L.: *Technique of Underwater Gymnastics*, Los Angeles, American Publications, Inc., 1937.

tioning well and there may be a tendency to swim the wrong way just to make progress through the water. That is why swimming should be supervised and the patient be made to swim correctly even though it may be the hard way.

It does not matter so much whether there is a large pool with varying depths of water or a smaller tub arrangement such as the Hubbard tub and its modifications, so long as we have carefully worked out the muscle groups, impaired joints and limitations of motion in order that we may write an intelligent and easily followed set of instructions for the physical therapist who will supervise the treatments.

Poliomyelitis has been in the public mind for years, and the idea prevailed that this disease alone was benefited by underwater therapy; but we have learned that the bulk of our patients will come from those having peripheral nerve injuries, either from disease or from trauma, patients showing poor coordination, those having spasticity, and arthritic patients with contractures and limited motion in joints. By reeducation we bring to the consciousness of the patient what should normally be expected of a group of muscles, and he in turn learns why he cannot perform acts normally and by reasoning begins to try to bring the right muscle or group of muscles into play in a normal manner. This is, of course, where we depend on a well trained physical therapist to see that the patient understands what muscles are defective and how to benefit from the exercises intended to bring about renewed function. One will see a knee joint which cannot be straightened, perhaps because of the patient's having slept with a pillow beneath the knee when the disease was in the acute and painful stage. Then there might be the same condition in an elbow or other joint. Frequently traction may gradually straighten such a joint; but it must be remembered that applying traction on the ordinary bed is not very pleasant to the patient because the body, on account of its weight, literally "hugs" the bed. However, when such traction is applied under water on a special table, the body floats free of the table and the patient, being much more comfortable, will allow more traction to be applied.

Children always like to play in water, which is one reason why they take to the pool as a plaything rather than a treatment; however, the physical therapist should know how much play to allow and how much serious thought should be given to the problem at hand. The little fellows, as in swimming by adults, might easily adopt wrong postures and wrong use of muscles if allowed to move about the easiest way.

Stress has been made on the fact that a physical therapist should be in attendance at all times. At Hot Springs National Park the Department of the Interior will not allow any one to take pool treatments without having been examined by a registered physician and under the care, in the pool, of a graduate physical therapist. Masseurs available in other departments for routine massage are not used in pool treatments except under supervision of the physical therapist.

It is required that the physical therapist make a complete chart of diseased muscles and joints when he first sees the patient after the doctor has made his examination and written his directions; then at frequent intervals he reexamines the defective parts and makes a written report to the patient's physician, thereby keeping him informed of the patient's progress and enabling the doctor, if he so desires, to advise the patient's home physician when the time comes for the patient to go

home. When these reports are received it is not infrequent for some changes to be found desirable.

One with a mechanical mind may devise any number of contrivances in a pool to take care of defective function. Bicycles, walking apparatus, floating objects, whirlpools, traction tables and any number of other devices come to mind when one begins to think of what one wishes to accomplish for the individual.

The water temperature of about 90 F. is much less than would be used in the other departments, and some doctors advocate pools of different temperatures for different types of involvement; but it should never be hot enough to bring about exhaustion from the exercises. The expense of heating and cooling water is no small item, but where natural hot water is available this expense is not a factor.

In the other types of baths one must have trained attendants who can follow written directions. Suppose I give a cross section of what may be obtained in this type of bath. The patient is first placed in a large tub with temperature ranging from 90 to 105 F. He may drink two or more cups of hot water and have a brisk rubdown with a bath mitt. If indicated he may go to a "head in" or "head out" cabinet for a few minutes, and this may be followed by a salt glow and scotch douche, or he may go to the sitz bath for five or more minutes at a temperature up to 105 F. Then he may go to the pack room, where hot wet towels are applied to the affected parts, and here he may drink more hot water. If perspiring freely he may wish a cool towel to the head. The next step is the needle shower and a good rubdown with a large rough towel, after which he goes from room to room, each being slightly cooler than the preceding one, until he has reached a temperature corresponding with that on the outside.

There are variations to the foregoing procedures too numerous to mention. Many patients will wish to go to the massage room after the bath or, in case of women, to the beauty parlor. A gymnasium is available at all bath-houses, and many persons may like to have a workout before going to the bath. The use of electrical apparatus is not allowed except in the pool, where muscles are tested for reaction of degeneration.

It can readily be seen that times and temperatures are important and must be considered when writing a bathing direction. For instance, a person with low blood pressure would not tolerate high temperatures and prolonged heat as well as one with a normal blood pressure. Then profuse sweating as induced by drinking water and going into cabinets would not be advisable in all cases. It is certainly advisable for every person to be examined before taking baths, but it has not been made obligatory.

Many patients with incurable diseases will go to a health resort year after year because they have derived some benefits and feel that the yearly visits are worth while. They have been made happier by doing so.

It is highly important that the home physician try to cooperate with the resort physician because, after all, the home physician has probably known the patient for many years and can make helpful suggestions which will be welcomed by the resort physician. Some physicians will tell their patients that they can do just as well in their own bathroom as they can elsewhere, but they lose sight of the fact that a supervised hydrotherapeutic program accomplishes something which cannot be accomplished by bathing in the home. Fortunately many physicians welcome the availability of spas for the treatment of some of their difficult patients, and I

have found it advisable and helpful to communicate with the home physician from time to time receiving and applying their suggestions. We of the spas always welcome a letter from the home physician when the patient arrives in our offices.

While baths "per se" may not be the whole story so far as "nervous" patients are concerned, these persons enjoy routine and "something to do" as a vacation from sedatives and other drugs, and the meeting of new people together with the new interests to which they have not been accustomed will enable patients to get away from that state where they may literally draw a circle about their feet and be unable to step out of it. The fact that year after year patients with organic and functional disease of the nervous system have returned to resorts is indication enough that benefits have been obtained by these visits, and this fact alone establishes the importance of resorts in the scheme of life and medical management of disease.

Council on Foods and Nutrition

THE COUNCIL ON FOODS AND NUTRITION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

GEORGE K. ANDERSON, M.D., Secretary.

THE MECHANICAL COW

The "mechanical cow" is a machine manufactured by the United Dairy Equipment Company of West Chester, Pa. The purpose of the machine is to mix water, spray-dried skimmed milk and butter to produce a product which can substitute for milk or cream according to the proportion of ingredients employed. The preparation of an ice cream mixture is also included among the purposes of the machine.

The machine contains a mixing-pasteurizing tank for starting the process; the final product passes over a cooler. The unique feature of the machine consists of a vertical cylinder nearly 2 inches in diameter rotating at high speed (22,000 revolutions per minute), which emulsifies, homogenizes and clarifies the product. The mixed, pasteurized product is drawn into the rotating cylinder from below by centrifugal force. Immediately above the intake a set of vertical blades, moving at the same speed as the cylinder, splashes the product against the cylinder wall with great force, partially emulsifying the mixture. Because of continued flow of milk from below, the thin layer of milk along the side of the cylinder passes upward toward the outlet at the upper end of the cylinder. During the passage upward the milk is under centrifugal pressure of between 200 and 300 pounds to the square inch. In this upward passage any particles heavier than milk cling to the wall of the cylinder, thus producing a clarifying effect. The top of the cylinder is capped by a disk with small circular holes at its periphery. The milk leaves these holes at a pressure of 200 to 300 pounds to strike against the side of the receiving chamber, thus further emulsifying and homogenizing the product.

The "milk" produced by the mechanical cow, if sold, would be required to have a label declaration other than milk or in addition to milk. Though it may be prepared wholly from milk constituents which have been separated and remixed, the product is not milk under the legal definition of this term. The term "reconstituted milk" presumably is legally applicable.

In most respects the "milk" produced by the mechanical cow has all the food value of fresh milk. However, it is well known that the heat treatment incident to pasteurizing and drying causes decrease in thiamine and ascorbic acid content. An analysis submitted by the manufacturer indicates that no ascorbic acid is present in the final product and that a loss of approximately 15 per cent occurs in the thiamine content. A further loss of thiamine seems likely with storage of the dried milk. Despite these losses, the product has high nutritional value and nutritionally is an excellent substitute for milk.

The product of the machine has a low bacterial content when all instructions have been followed. The instructions include

rigid cleanliness of the machine. It is the preference of the manufacturer that the butter and dried skimmed milk be obtained from him, thus possibly making more certain that the components of the product have a low bacterial content. Normally dried skimmed milk may be expected to have few living bacteria. The butter recommended is prepared from sweet pasteurized cream and is unsalted. Salted butter may be used by means of an additional centrifugal bowl which will produce a salt-free butter. The pasteurizing of cream for butter making is commonly carried out at a temperature higher than that used for the pasteurization of milk, thus tending toward a lower bacterial content. Starting with components having few bacteria, and with pasteurizing of the mixture at the beginning of the process, the bacterial content should compare favorably with that of good certified milk which has been pasteurized. The manufacturer states that under conditions of testing the average number of bacteria is approximately 100 to the cubic centimeter.

The manufacturer of the mechanical cow has foreseen a shortage of butter in various parts of the world and the lack of refrigerated shipping space for its transport. Vitamin fortified vegetable oil substitutes for butter have been devised which make a product acceptable as to taste and which can be shipped and stored more easily than butter. The "milk" prepared with such a butter substitute would be the equivalent of "filled milk." Though such a product would have many nutritional virtues, it is one which has little legal standing in this country. The Council on Foods and Nutrition cannot give its approval to illegal products.

The principle of production of "milk" by the mechanical cow merits approval when dried skimmed milk, butter and water are the ingredients. Dried skimmed milk and butter have keeping qualities not possessed by fresh milk. The machine is useful in supplying a good substitute for milk and cream. It is useful on ships and in regions where dairies are inadequate or nonexistent. Many such regions exist in this country, and their number has been increased because of war conditions. Since the product can be prepared under some circumstances at a cost somewhat less than that of fresh milk for retail distribution, conceivably it could enter into competition with fresh milk.

ACCEPTED FOODS

THE FOLLOWING ADDITIONAL FOODS HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON FOODS AND NUTRITION OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO ACCEPTED FOODS.

GEORGE K. ANDERSON, M.D., Secretary.

CANNED AND DRIED FRUITS AND FRUIT PRODUCTS (See Accepted Foods, 1939, p. 70).

Pasco Packing Association, Dade City, Fla.

OLD SOUTH BRAND CONCENTRATED ORANGE JUICE, a pasteurized orange juice concentrate formed by evaporating freshly expressed orange juice under reduced pressure to a Brix of 65 degrees. It is pasteurized, but the firm recommends that it be kept at a temperature of 45 degrees or less.

Analysis (submitted by manufacturer).—Moisture 28%, ash 1.8-2.0%, fat (ether extract) 1.0%, protein (N \times 6.25) 5-6%, sucrose 28%, reducing sugar 28%, citric acid 3.9-6.0%, ascorbic acid 180-300 mg. per hundred grams, specific gravity 1.33.

Calories.—2.4 per gram; 68.16 per ounce.

Vitamin Claims.—Ascorbic acid (determined by the Dye method) on the basis of the median of range reported, using a dilution of 6% additional parts of water (firm recommends addition of six or seven parts); the resulting drink contains 49.6 mg. of ascorbic acid per hundred cubic centimeters.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156).

Gerber Products Company, Fremont, Mich.

GERBER'S CHOPPED VEGETABLE AND BEEF WITH RICE, consisting of potatoes, water, celery, beef, tomato pulp, carrots, rice, salt and onion powder.

Analysis (submitted by manufacturer).—Moisture 87.8%, ash 1.3%, fat 0.5%, protein (N \times 6.25) 2.8%, crude fiber 0.4%, carbohydrates (by difference) 7.2%, Ca 0.018%, P 0.037%, Fe 0.0021%, Cu 0.00029.

Calories.—0.4 per gram; 13 per ounce.

Vitamins.—Protocols of vitamin assay (1941) show that this product contains 1,400 international units of vitamin A, 0.032 mg. of thiamine and 1 mg. of ascorbic acid for each hundred grams.

SATURDAY, AUGUST 12, 1944

AID TO PHYSICALLY DISABLED

Plans are being formulated by a subcommittee of the House Committee on Labor, of which Congressman Kelley of Pennsylvania is chairman, for an extensive survey of the extent and character of aid given by the federal, state and local governments and by private agencies to the physically handicapped. This survey is to be conducted under authority of a House resolution adopted by the House of Representatives June 20. According to the chairman of the subcommittee, it was estimated that before Pearl Harbor some 800,000 people became physically handicapped each year. Since that time the number has increased greatly. The survey will be designed to explore the problem of unemployment of the physically handicapped persons in the United States, estimated at some 25,000,000, and to provide a means whereby Congress may be possessed of the requisite knowledge to deal with the problem. All categories of the physically handicapped, it is understood, will be covered by the study, including persons with amputated limbs and with cardiac disorders, victims of infantile paralysis, the blind, the deaf and the hard of hearing. The subcommittee, on the basis of information it obtains, is expected to submit a program to Congress for the assistance of the physically handicapped to the end that they may be profitably employed. The extent to which this program may involve an extensive health program for the physically disabled cannot at this time be accurately anticipated.

Proposals to amend the Social Security Act specifically to provide benefits for the adult physically disabled have been made from time to time. Several bills of this type are now pending in Congress before the House Committee on Ways and Means and the House Committee on Education. The Congress has only recently enacted broad legislation for the rehabilitation of disabled veterans, which program will be under the administrative guidance of the Veterans' Administration. It has also extensively revised the

Federal Vocational Rehabilitation Act to provide for the physical restoration of civilians, and this program is being administered by the Federal Security Agency.

Chairman Kelley, in referring to the uncorrelated existing programs, said that at the present time something like eighteen different governmental agencies have something to do with the physically handicapped. The need for a consolidation of federal activities in the field of health and related fields has been recognized by the House of Delegates for many years. If the Kelley subcommittee will recommend that federal activities relating to the physically handicapped be consolidated in an appropriate federal agency, such as the Federal Security Agency, and if that recommendation is accepted by the Congress, another step will have been taken to effect a long delayed—too long delayed—simplification of federal participation in health and allied programs. Hearings will be scheduled by the Subcommittee to Investigate Aid to Physically Handicapped within the near future.

VIRULENCE OF PENICILLIN RESISTANT BACTERIA

Encouraging new data regarding the virulence of penicillin resistant staphylococci are reported by Spink and his associates¹ of the division of internal medicine, University of Minnesota Medical School. As a result of an inadequate therapeutic dose or of test tube exposure to nonsterilizing concentrations of penicillin, pathogenic bacteria may become penicillin resistant. This acquired resistance is a relatively stable hereditary characteristic of the micro-organisms, persisting through innumerable test tube generations. Generally it is assumed² that micro-organisms with this acquired penicillin resistance do not show other changes in their biologic and metabolic characters and thus constitute an additive epidemiologic danger.

Spink isolated four strains of coagulase positive staphylococci from osteomyelitic lesions in children, with a later duplicate strain from 1 child after it had received inadequate therapeutic doses of penicillin. The four strains thus obtained were approximately equal in their resistance to penicillin, growth being completely inhibited by the addition of from 0.04 to 0.06 Oxford unit per cubic centimeter of culture medium. The four strains were gradually adapted to penicillin by daily transfer to culture medium containing increasing concentrations. Control daily transfers in penicillin free medium were made with each strain. After a hundred or more serial transfers each strain had become penicillin resistant. With two of the strains complete

1. Spink, W. W.; Ferris, V., and Vivino, J. J.: *Proc. Soc. Exptl. Biol. & Med.* 55: 210 (March) 1944.

2. Abraham, E. P.; Chaim, E.; Fletcher, C. M.; Gardner, A. D.; Heatley, N. G.; Jennings, M. H., and Florey, H. W.: *Lancet* 2: 177 (Aug. 16) 1941.

inhibition of growth now required as much as 80 to 120 Oxford units per cubic centimeter, or 2,000 times the penicillin concentration necessary for complete inhibition of the parent strain. These two strains were transferred to veal-agar slants and placed in a refrigerator for three months, at the end of which period they showed no decrease in their acquired penicillin resistance.

The acquired penicillin resistance was associated with morphologic changes in each culture. Each resistant strain showed pleomorphism, with large spherical cell bodies quite apparent. Two of the parent strains produced a brown-orange pigment under certain culture conditions, which pigment was greatly decreased in amount in the homologous adapted strains. In four of the five adapted strains the rate of test tube proliferation was distinctly slower than with the parent culture. These facts suggest both a morphologic and a metabolic deterioration of staphylococci as a result of the acquired penicillin resistance, giving rise to the hope that the adapted strains are of reduced pathogenicity or virulence.

To test this hoped for loss of virulence Spink adopted a technic previously developed in his laboratory,³ that of titrating the resistance of each strain against the bactericidal properties of defibrinated normal human blood. To each 0.5 cc. of fresh defibrinated blood there was added 0.1 cc. of a serial dilution of twenty-four hour broth cultures of the organism to be tested, seven 1:10 serial dilutions being tested with each strain. The approximate number of organisms thus added to each test varied from approximately 25,000,000 down to 25. The tubes were then sealed and rotated for forty-eight hours at incubator temperature, at the end of which time the contents of each tube were tested for sterility.

In a typical experiment the 25 penicillin susceptible staphylococci in the seventh tube failed to grow, while the first to sixth tubes did not become sterile. The 0.5 cc. blood sample used in this test was therefore able to kill between 25 and 250 penicillin susceptible staphylococci, or approximately 275 staphylococci per cubic centimeter. In a parallel test with a homologous penicillin resistant strain a duplicate human blood sample killed between 11,000 and 110,000 adapted staphylococci, or approximately 120,000 staphylococci per cubic centimeter. The penicillin resistant strain was thus four hundred times more susceptible to the bactericidal properties of human blood than the parent strain from which it was developed. Similar decreases in microbic vigor were demonstrated for all penicillin resistant strains thus far tested.

These results are in contrast to results of a parallel study of strains of staphylococci adapted to grow in

the presence of sulfonamides. Defibrinated human blood has no greater bactericidal action on sulfonamide resistant strains than on the parent sulfonamide sensitive strains from which they were developed. If adequately confirmed, these results suggest that, while sulfonamide resistant strains of staphylococci may function as an additive epidemiologic danger, acquired penicillin resistance of staphylococci is of relatively little hygienic interest. No theory is as yet suggested to account for this difference. Whether or not the same difference is demonstrable in micro-organisms other than staphylococci has not yet been reported.

WORKMEN'S COMPENSATION FOR CANCER ASCRIBED TO SINGLE INJURY

Under workmen's compensation acts a claim that a workman has died or been disabled because of a cancer resulting from an industrial accident is decided in the first place by an industrial board or some equivalent tribunal. Such tribunals, even though without legally qualified physicians and lawyers among their members, have to decide questions of law and of fact as they arise and make their awards accordingly. The laws governing appeals from such awards vary in the different states, but in many states an appellate court may set aside an award or remand a case to the industrial board for further proceedings only because of errors of law. The board's findings as to fact are not open to review except that the appellate court may determine whether such findings are based as the law requires on reasonable evidence.

Whether or not a fatal or disabling cancer was caused by an industrial accident is certainly a question not of law but of fact. If reasonable evidence has been introduced in the proceedings before an industrial board to sustain a finding that an industrial injury, single or multiple, has caused a cancer that resulted in disability or death and the industrial board so decides, an appellate court in any state in which the general rule laid down above is in force cannot set aside the award or remand the case for further proceedings, even though the court believes that the weight of all the evidence in the case did not justify the decision.

Appeals from decisions of industrial boards and similar tribunals awarding compensation for death or disability attributed to cancer supposed to have resulted from industrial accidents seem to be, therefore—in most states, at least—hardly a satisfactory remedy for errors of judgment in making such awards. Rather it would be better, without denying that a cancer may be caused by a single injury, to organize our industrial boards so as to enable them better to weigh the medical evidence that comes before them. This suggestion should not be construed as a reflection in any way on the work

J. Spink, W. W., and Paine, J. R. *J. Immunol.* 38:383 (May) 1940.

of such boards, for with the aid of their medical assistants their work is, it is believed, generally well done. As a further means of avoiding injustice in the making of awards, appellate courts should be vested with the right to set aside or to remand for further proceedings cases in which decisions seem to be clearly contrary to the weight of the entire evidence even though there may be some reasonable evidence to support them.

In any event, as long as the cause or causes of cancer are not known, as long as there may be an opinion among the medical profession at large to the effect that a single trauma may cause cancer and as long as physicians are willing to testify under oath that in their professional opinions a single trauma can cause and has caused cancer in the case before the industrial commission, industrial commissions cannot be blamed if sometimes they accept such evidence and grant awards accordingly.

In forming his opinion in a given case the physician should bear in mind the lack of definitive knowledge with regard to the relation of a single injury to the causation of cancer. Whether human cancer can be caused by a single accidental injury remains an open question. The results of clinical observations on the question are not conclusive. While authentic cases are recorded in which cancer arose at the site of an injury, the possibility that it was under way before the injury was received or that it developed independently of the injury cannot be excluded. That cancer can and does arise independently of injury and that single injuries become associated with cancer in one way or another only in extremely few cases will not be denied. As far as known, cancer in animals has not been produced experimentally by single mechanical injury.

Current Comment

PENICILLIN AS AN INHALANT

Under the auspices of the Long Island Biological Association Bryson, Lansome and Laskin¹ studied the behavior of penicillin as an inhalant. With a standard glass nebulizer a solution of the sodium salt of penicillin was readily nebulized for inhalation. Experiments on rabbits and on human beings demonstrated that in such form penicillin passed through the respiratory tract and appeared in the urine. In rabbits penicillin was recovered from the lung tissue after inhalation. As penicillin is bacteriostatic for pneumococci, streptococci and staphylococci in extremely high dilutions, its inhalation as an aerosol may be of advantage in the treatment of respiratory infections with these and perhaps also other bacteria. The results of further experiments will be of interest. The question also arises whether penicillin will be of value as an air disinfectant.

CLEVELAND HEALTH MUSEUM

Many museums in the United States are contributing greatly to health education of the public. Some of these museums present their health exhibits in cooperation with local medical societies, while others operate under the guidance of physicians interested in health education. The Cleveland Health Museum has shown leadership in this field, and the medical profession has had a large part in its success. Organized under the auspices of the Cleveland Academy of Medicine to serve the people of Cleveland, the museum is rapidly becoming a national institution. Its exhibits have been used in seventeen states of the Union, as well as in Canada and Mexico. Health educators from various parts of the United States and from the Latin American countries have taken advantage of the intern training in visual health education offered by the museum staff. The appointment of a National Advisory Council indicates a further extension of these activities.

FOUR GENERATIONS OF SACROILIAC ARTHRITIS

Among disorders which involve the joints, the importance of heredity is recognized only in gout, rheumatic fever and probably certain degenerative forms of joint disease. An analysis of the exact mechanism played by genetics is difficult, however. Indeed, this has not yet been clarified even in gout and gouty arthritis, in which hereditary influences appear especially strong. Now Stauffer and Merrihew¹ show the pedigree of a form of arthritis that was present in a family in western New York State for at least four generations. The pedigree shows 22 affected persons in these four generations with a ratio of 21 arthritic persons to 12 normal (when siblings not old enough to have developed the disease were eliminated). All of the affected persons suffered pain in the sacroiliac region, and some also had sciatic pains and tingling and swelling of the extremities. The data for this study were collected by personal interview with affected and unaffected members of the family, most of whom were still living. The condition was encountered for the most part either in persons who were somewhat obese or who performed work of a manual nature. This suggests that the strain imposed by overweight or by the exertion from lifting may be direct factors in the onset of pain. The presence of excess uric acid in the urine in some persons, as well as symptoms of kidney disease, suggested to the writers that renal defects were present, but whether these were basic or merely symptomatic could not be decided. Possibly, these workers suggest, the basic action of the gene is to influence purine metabolism, and the renal disorder is secondary. If this should be the case, the disease in this family would appear to be more closely allied to the arthritis of gout than to any other form of joint disease. Whether this is correct or not, the writers feel confident from the similarity of symptoms in the afflicted members of the family reported that the disease is a genetic entity and the mechanism of inheritance is probably dominant.

MEDICINE AND THE WAR

DEFERMENT OF PREMEDICAL AND MEDICAL STUDENTS

Following is the reply of Major General Hershey, Director of the Selective Service System, to a memorandum submitted to him by Senator Lucas of Illinois, and comments on General Hershey's letter by the Council on Medical Education and Hospitals of the American Medical Association:

NATIONAL HEADQUARTERS SELECTIVE SERVICE SYSTEM

21st Street and C Street NW.
Washington 25, D. C.

July 24, 1944.

*The Honorable Scott W. Lucas,
United States Senate.*

Dear Senator Lucas:

This will acknowledge your memorandum of July 15, 1944.

A survey made at this Headquarters indicates that there is undue concern over the future supply of doctors. The military forces demand medical attendance out of proportion to that demanded by the civilian population, and, during this period of emergency, civilian medical attendance, like everything else, must be limited to necessity. After the war there will be an adequate number of physicians, for there are now in the medical schools a number of students greater than the number which ordinarily study medicine in peacetime. In the accelerated program it is expected that all of these will finish their internships and be ready for practice by 1949. Our investigation revealed that we will then have not less than 193,000 doctors in the population as a whole. There will be one physician for approximately each 733 persons. The publications of the American Medical Association indicate that there was one doctor for each 765 persons in 1938, when the last figures were made public. Our figure for 1949 is based on a population estimation made at this Headquarters and by adding students now in college and to be graduated before 1949 to the American Medical Association's 1944 figures, less the expected attrition. The increased need for physicians is recognized, but it would seem that this excess over our past requirements would be adequate to meet future demands.

The concern is principally over the future shortage of doctors because it is alleged that no premedical students are being educated for the freshman classes to enter medicine in 1945. The question of the deferment of preprofessional students has been given much consideration. The armed forces have provided for the utilization of 53 per cent of the capacity of the classes in medical schools in 1945. This leaves only 47 per cent of the capacity which may be filled by civilian students. To find the number to prepare in premedicine and to fill these vacancies there is available a large number of men between 18 and 26 years of age found physically disqualified for any military service or physically qualified for limited military service only; women; soldiers discharged from the Army, and men over 30 years of age. Those men found physically disqualified for military service are frequently disqualified by reason of conditions which will not prevent them from being eligible for the study of a profession. It is incumbent upon the educational institutions to find in this group the men they want, and to offer them the inducement necessary to get them to study the professions.

Any additional students who are necessary to qualify for entrance into the medical, dental, osteopathic and veterinarian schools should be taken from the armed forces and from those who have spent at least two years in active service. The morale of the country will be definitely injured by continuation of a policy which will permit a boy becoming 18 to enter successively preprofessional and professional schools without fulfilling any military obligations. An application of this system

will be equally injurious to the medical, dental, osteopathic and veterinarian professions. This is true, first because men will become doctors, missing the major civic experience of this age for young men. The professions will be the poorer because they will find that they have doctors who are immature in years as well as in experience, and whose professional information was acquired in accelerated courses both in preprofessional schools and professional schools. This can be avoided by the selection of competent, mature, experienced men who have fulfilled their duties of citizenship to their country in war.

Dr. Willard C. Rappleye, Chairman of the Executive Council, Association of American Medical Colleges, Dr. A. W. Bryan, President, American Association of Dental Schools, and Mr. William N. Hodgkin, Chairman, Council on Dental Education, American Dental Association, have recommended to me that the Army and the Navy demobilize, either by furlough to the Reserve or by discharge, men selected because they have had at least two years of military service, have had preprofessional training to a degree which will make it possible in a nine month course to prepare them for entrance into the professional schools, and who are anxious to enter the professions under discussion. This plan was submitted to the Secretary of War and the Secretary of the Navy in an identical letter on June 6, 1944. A joint reply was received on June 29, 1944, indicating that the recommendation had not been favorably considered.

I am firmly of the opinion that the project submitted by Dr. Rappleye, Dr. Bryan and Mr. Hodgkin furnishes the only satisfactory solution to this problem if additional students are required for the preprofessional schools.

We are returning the attachment which accompanied your memorandum.

Sincerely Yours,
LEWIS B. HERSHEY,
Director.

Comment by Council on Medical Education and Hospitals

There are four major points made in General Hershey's letter which may be seriously questioned on the basis of information collected by the Council on Medical Education and Hospitals from the schools of medicine of this country:

1. "There is undue concern over the future supply of doctors." It is also stated that there will be more doctors available after the war than before the war. This is not all clear. In the first place, significant numbers of the physicians in the United States do not directly participate in providing medical care. These physicians are otherwise engaged or retired. Therefore physician-population ratios cannot be computed from the total number of physicians. The figures pertaining to increases or decreases in physicians available to civilians in the next few years are plain. Under the accelerated program there were 10,357 graduates from July 1, 1942 (when acceleration started in most schools) to June 30, 1944. Based on figures submitted by each school, it is estimated that an additional 9,844 will graduate from July 1, 1944 to June 30, 1945. This totals 20,201 graduates during a complete three calendar year cycle involving four graduating classes. If acceleration is continued even though admissions are made annually, there will be an additional approximately 20,000 graduates in the ensuing three year cycle from July 1, 1945 to June 30, 1948.

During this whole six year accelerated period there should be approximately 40,000 graduates. During the six prewar

years July 1, 1935 to June 30, 1941 there were 31,215 graduates. All other things being equal, these figures would indicate an increase in the physician population by 8,785 in 1948.

But all other things will not be equal. This entire surplus physician population would be absorbed by a standing army of 1,757,000 men at 5 medical officers per thousand men. Should the standing postwar navy require 5,000 physicians and the Veterans Administration 10,000, the physician population available to civilians would actually be reduced by 15,000 instead of increased.

In these calculations no account is taken of general population increases, fatalities and incapacitating injuries among medical officers in service, the current increased death rate among physicians, increasing demands of the civilian population for improved medical care, requirements for American physicians in the rehabilitation of liberated countries and the possible permanent damage of some of the "plant" of medical education through possible failure of some schools to continue operation with greatly reduced enrolments. Concern over the future supply of doctors is fully warranted under these conditions.

2. ". . . Forty-seven per cent of the capacity (of entering classes) . . . may be filled by civilian students (in 1945)." The deans of all medical schools were asked "How great a reduction do you estimate there might be in your 1945 entering classes if you are forced to select 41 to 47 per cent civilians, with no selective service deferments?" In response, the deans of only nine schools thought they might be able to fill civilian places under these conditions. Fifty-seven schools estimated reductions of from about 10 to over 40 per cent in freshman enrolments. There was an average reduction of 23 per cent for the sixty-six schools venturing estimates. The remaining eleven schools were unwilling or unable to estimate reduction which will occur.

It should also be recalled that the provisions of the current army appropriation bill, by abolishing further admissions of trainees to the A. S. T. premedical program, increase to 70 or 75 per cent the number of students which must be obtained from civilian sources in 1946.

3. Students are available from "a large number of men between 18 and 28 years of age found physically disqualified

. . . ; women; soldiers discharged from the Army and men over 30 years of age." These possible sources were taken into consideration in the estimates of reduced enrolments made in the preceding paragraphs. It is extremely doubtful whether qualified students in these categories are available in significant numbers at present unless admission standards are drastically reduced. There is no evidence of the existence of a large reserve pool of qualified women. Some physically disqualified and discharged men might be physically able to study and practice medicine, but these occupations are arduous, requiring vigorous health, and are not for the physically unfit. Many of those discharged are sufficiently unstable emotionally to prevent their becoming good doctors. Also there is no doubt that this group includes many men who have been previously rejected for admission to medical schools because they failed to meet admission standards, even though they may have pursued premedical studies before the war. While every favorable consideration should and will be given to medical school applications from veterans, it would serve neither the veteran nor the public to admit to medical schools men who do not possess the requisite physical, emotional, mental and other qualifications.

It will not meet the problem of obtaining students from these groups "to offer them the inducement necessary to study medicine." Students are impelled to study medicine through a long and complicated series of circumstances involving their whole past education, drives, capacities, emotional and social experiences, and not by offering special inducements.

4. "Additional students . . . should be taken from . . . those who have spent two years in active service." Much of what has been said above applies to this suggestion. Even if the Army and Navy had not rejected this plan, it probably would have resulted in many men being returned from the widespread theaters of military operations and even from this country, who would not possess the qualifications for the study of medicine. The commanding officers in Asia and Africa and Italy and France, or even the United States, with their many heavy responsibilities and inexperience in selection of medical students would be scarcely in a favorable position for collaborating with deans many miles away in assigning capable men to medical studies.

ARMY

PROCEDURES GIVEN FOR A. S. T. P. MEDICAL, DENTAL PROGRAMS

Procedures for disposal of certain enlisted personnel in the Army Specialized Training Medical Program necessitated by provisions of the Military Appropriations Act, 1945, have been announced by the War Department. The act, approved June 28, 1944, stipulated that none of the funds appropriated shall be used for training medical and premedical students unless they were in training prior to June 7, 1944, and such training was defrayed from 1944 appropriations.

At the same time, it was announced that the A. S. T. P. dental training program is being terminated at the close of the present semester except for those in the senior, or final, year, who will be permitted to complete the course and on graduation will be commissioned. This action is taken because the Army's requirements for dentists are now filled.

Those individuals now on active duty whose medical or premedical educational expenses were defrayed in whole or in part by the government under the A. S. T. P. program prior to June 7, 1944 will be continued in the medical program of the A. S. T. P. Those on active duty whose medical or premedical training was not defrayed either in whole or in part under the A. S. T. P. program prior to June 7, 1944 and who for that reason cannot be continued in the training program fall into two classes who will be disposed of as follows:

1. Those who have letters of acceptance and who would have entered an accredited medical school by Dec. 31, 1944. An individual in this group may elect to be discharged from the Army shortly before the entrance date of the class for

which he was accepted; or to be assigned to the Medical Department with no further A. S. T. P. medical training.

2. Those who do not have a letter of acceptance to an accredited medical school, for entrance by Dec. 31, 1944. These men will be continued on active duty and will not be eligible for A. S. T. P. medical training.

COMMANDING OFFICER AT HALLORAN APPOINTED BRIGADIER GENERAL

Halloran General Hospital, Staten Island, N. Y., was the recipient of one of the most signal honors in its distinguished history as an army hospital when Col. Ralph G. DeVoe, commanding, was promoted to Brigadier General May 24. The June 30 issue of the *Halloran Beacon*, Post Publication at Halloran General Hospital, is a tributary volume to Brigadier General DeVoe.

Brigadier General DeVoe graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1908 and from the Army Medical School in 1910. Before World War I broke out he was stationed in the Philippines, where he was promoted to captain in 1913. He became a first lieutenant in the Medical Reserve Corps in 1919 and was promoted to major on May 15, 1917. In September 1917 he became commanding officer of Base Hospital 34 in Nantes, France, and in November 1918 he was made commanding officer of the Hospital Center in Nantes. For this service he was awarded the decoration of Chevalier of the Legion of Honor by the French government, and on May 5, 1919 he became a colonel in the Medical Corps of the U. S. Army.

NAVY

HOSPITALIZATION OF DEPENDENTS
OF NAVAL PERSONNEL

Instructions have been issued by the Navy Department to govern the hospitalization of dependents of naval personnel in accordance with the act of May 10, 1943, which provided for expansion of facilities for hospitalization of dependents of naval and Marine Corps personnel. The instructions, dated June 10 but just published, define dependents as wife, unmarried dependent children under 21 years of age and mother and father if in fact dependent. Widows of deceased naval and marine personnel also are entitled to hospital care in the same manner as dependents. The Navy Department has authority to designate naval hospitals to which dependents shall be admitted and may remove such designation or add to the list of designated hospitals at any time. The commanding officer of the designated hospital shall determine the availability of accommodations for dependents and their need for hospitalization, reserving sufficient facilities for present and prospective naval personnel patient loads. Dependents shall be admitted only for acute medical and surgical conditions, exclusive of nervous, mental or contagious care. Dental treatment shall be administered only as an adjunct to inpatient hospital care and shall not include dental prosthesis or orthodontia. For each patient admitted and for each day in the hospital, the member of the Navy or Marine Corps concerned shall pay \$7.75. While the Coast Guard is operating as part of the Navy, dependents of Coast Guard personnel are entitled to hospitalization on the same basis as members of the other sea services.

NAVY AWARDS AND COMMENDATIONS

Captain Jesse D. Jewell

The Navy Cross was recently awarded to Capt. Jesse D. Jewell "for distinguished service in line of his profession, extraordinary courage and disregard of his own condition during an attack on the fleet in Pearl Harbor on Dec. 7, 1941. Although burned about the face and arms from fires nearby

his station on board the U. S. S. *California*, he continued at his post of duty and administered effective first aid." Dr. Jewell graduated from the University of Oregon Medical School in 1918 and entered the service in July 1921. He is now executive officer of the U. S. Naval Hospital at Corona, Calif.

PROMPT EVACUATION OF CASUALTIES
GREATEST SINGLE FACTOR IN
SAVING LIVES

Medical officials at Saipan, Marianas Islands, believe that the greatest single factor in saving the lives of wounded Marines on this island is the prompt evacuation of casualties to mobile field hospitals close behind the front. At one of these hospitals, with Comdr. R. L. Sharp, formerly of Morristown, N. J., in charge, it was revealed that fewer than 1 per cent of all casualties brought to the hospital prove fatal. "If a man is not killed instantly, and if he can be brought to us within an hour or so after being wounded we can almost guarantee to save his life," Dr. Sharp stated. The average time for evacuating a casualty is about an hour, he said. Ambulance jeeps go as close to the front as practical, and stretcher teams working in relays carry the wounded to the jeeps, and they are usually on the operating table within an hour after being picked up. Five doctors, including a surgeon, an orthopedic specialist and a dentist are on hand at all times. They are assisted by 75 Navy pharmacist's mates and 25 Marine orderlies. The hospital is equipped with 100 beds and a surgical ward which includes an x-ray machine and special operating instruments. It maintains its own sanitary cooking galley, so that special diets can be prepared when necessary. Patients are returned to the rear lines as quickly, as practicable to make room for new casualties. "While the sulfonamide drugs have done wonders in preventing infection and plasma has performed miracles in overcoming shock, it is speedy evacuation that really saves lives," Dr. Sharp said. "Sulfonamides, plasma and evacuation," he emphasized, "are like the legs of an equilateral triangle, each dependent on the others."

MISCELLANEOUS

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, July 29, page 918)

CALIFORNIA

Santa Clara County Hospital, San Jose. Capacity, 470; admissions, 4,435. Dr. Henry E. Dahlgren, Superintendent (resident—tuberculosis).

CONNECTICUT

The Meriden Hospital, Meriden. Capacity, 139, admissions, 3,802. Dr. Herbert T. Wagner, Medical Director (interns—October 1).
Waterbury Hospital, Waterbury. Capacity, 372, admissions, 8,144. Miss Aida E. Crecer, R.N., Superintendent (resident—October 1).

LOUISIANA

T. H. Schumpert Memorial Hospital, Shreveport. Capacity, 120; admissions, 3,631. Sister Mary Celestine, Superintendent (interns).

MINNESOTA

University Hospitals, Minneapolis. Capacity, 450; admissions, 9,187. Mr. Ray M. Amberg, Superintendent (resident—orthopedics, August).

NEW YORK

Israel Zion Hospital, Brooklyn. Capacity, 380, admissions, 10,532. Dr. J. Prager, Executive Director (interns—October 1944, January 1945).
St. Mary's Hospital, Brooklyn. Capacity, 328, admissions, 5,004. Sister Mary Helen, Superintendent (interns).
Mount Vernon Hospital, Mount Vernon. Capacity, 254; admissions, 5,749. Mr. Arthur B. Solon, Superintendent (interns—October 1).

Beth David Hospital, New York. Capacity, 150, admissions, 3,985.

Mr. Harold Salkind, Executive Director (interns).

New York Post Graduate Medical School and Hospital, New York. Capacity, 409, admissions, 8,622. Dr. William B. Talbot, Medical Superintendent (resident—urology).

OKLAHOMA

St. John's Hospital, Tulsa. Capacity, 273, admissions, 10,327. Sister M. Olga, Superintendent (interns).

WEST VIRGINIA

St. Francis Hospital, Charleston. Capacity, 118, admissions, 4,923. Sister Mary Paul, Administrator (2 residents—mixed, October 1).

PHYSICIANS PHYSICALLY DISQUALIFIED
SINCE JULY 1943

An agreement has been reached with the Surgeons General of the Army and Navy that: 1. Physicians who have been physically disqualified for service in the armed forces since July 1943 and who are now serving in an essential capacity as an intern, resident, teacher or other hospital appointee will not be asked to submit to reexamination or to activate or reapply for a commission without a standard form 97 indicating that they are currently available. 2. Physicians physically disqualified for service in the armed forces and now in essential hospital positions who are being reconsidered for a commission in the armed forces will not be called to active duty until the expiration of their present obligation, provided form 218 for each physician is submitted covering such period of service.

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

July 7, 1944.

American Academy of Pediatrics Withdraws Support from Children's Bureau

Further evidence of opposition to a trend toward socialized medicine was noted here in the action of the American Academy of Pediatrics in withdrawing its support from the Children's Bureau because its system of emergency maternity and infant care is an entering wedge for socialized medicine.

Last month a conference of child specialists and social workers here took a stand against the bureau's group care of children, asserting that group care was damaging to child welfare and actually more expensive than a foster family system of care which the conferees advocated. The academy announced its position in the *Journal of Pediatrics* as follows: "We feel the time has come when the academy and the pediatricians of the United States must withdraw their support from the Children's Bureau and use their influence as a group and as individuals to place all health activities under the Public Health Service."

Records of the Children's Bureau show that since the beginning of the program in March 1943 through May 1, 355,000 mothers and babies of servicemen received federal aid under the program for which Congress appropriated \$42,800,000. Entitled to care under the program are wives and infants of men in the four lowest paid grades of the armed forces.

The academy withdrew its support despite insistence of Dr. Martha M. Eliot, assistant chief and chief medical adviser of the bureau, that "EMIC will disappear when the war is over."

The pediatricians, in throwing their support from the Children's Bureau to the Public Health Service, are transferring it from an agency dominated by social workers to the medical authorities wielding balance of power at Public Health Service.

Dr. Eliot says in defense of the program that Congress brought it into existence as a wartime measure. She denied that the Children's Bureau intended to enter the practice of medicine after the war or to continue the emergency medical and infant care program in some other guise.

Pediatricians argue that the wartime program had made the Children's Bureau an active factor in the practice of medicine in this country "dictatorially regulating fees and conditions of practice on a federal basis." It quoted articles issued by the bureau as indicating that it is evident that "a free to all service, with full time salaried physicians, paid for directly from general taxes and controlled and directed by a federal bureau," is planned. The average EMIC payment is reported to be about \$84 a case.

National War on Tuberculosis

The ninety-two United States cities of 100,000 or more population will be major battlefields of the war on tuberculosis to be waged under the national tuberculosis control program, for which some \$10,000,000 was authorized. About one out of every three tuberculosis deaths occurs in these cities, and the average tuberculosis death rate in them is about one third higher than in smaller towns and rural areas.

In making this announcement, Dr. Herman E. Hilleboe, chief of the U. S. Public Health Service Tuberculosis Division, said that tabulations based on census figures for the 1939-1941 three year period show variations in tuberculosis death rates of cities ranging from as low as 15.6 per hundred thousand among white in Grand Rapids, Mich., to as high as 275.5 per hundred thousand among nonwhite persons in Newark, N. J. A survey showed tuberculosis to be three times as fatal to the nonwhite as to the white, according to death rate figures. Women living in country areas were said to be more susceptible to the disease, although death rates were higher among men in metropolitan than in rural areas.

Syphilitic Registrant Reclaimed by Treatment

Of more than a quarter million Selective Service registrants reclaimed for military duty after blood tests indicated that they were infected with syphilis, some 125,000 have already enlisted or have been inducted into the armed forces and 140,000 more are available unless otherwise disqualified. These figures, announced by the U. S. Public Health Service, are based on tabulations of data up to June 30, 1943 from twenty-two states, on 182,607 of the 720,000 registrants with evidence of syphilis. Symptomatic evidence of syphilis was reported as having been revealed among 720,000 of the first 15,000,000 registrants given blood tests for syphilis. The job of tracing, treating and inducting a large number of the infected registrants was accomplished by cooperation among Selective Service boards, state and local health departments, the Army and the Navy.

Nurse Corps Seeks 60,000 More Cadets

In calling for enrolment of at least 60,000 more cadets this year to meet increasing needs for hospital personnel, the U. S. Public Health Service paints a bright postwar future for girls joining the U. S. Cadet Nurse Corps. They will serve a vital war purpose in preventing closing of wards and curtailment of hospital services, with virtually all hospitals extremely short handed. After the war, many new fields are expected to be open to women in the nursing profession, the following being cited as possibilities: expansion of community health services, widening of group hospitalization and developments in industrial safety and first aid programs.

WOMAN'S AUXILIARY

Indiana

At a recent meeting of the Clark County Auxiliary, "Cancer Control" and the Wagner-Murray-Dingell bill were discussed.

Pennsylvania

The Philadelphia County auxiliary distributed 6,000 copies of the Wagner-Murray-Dingell bill arranged by Dr. Francis F. Borzell. During the present year the auxiliary gave \$1,300 to the Aid Association of the Philadelphia County Medical Society and \$200 to the benevolent fund of the state society. The fourteenth annual health institute was held in April in the Philadelphia County Medical Society building, with fifty-three organizations participating.

The Philadelphia auxiliary celebrated its nineteenth birthday April 14. Mrs. Lowmes, the president, presented a memory book to the auxiliary containing the names of the past presi-

dents. Nine past presidents were present and received pins of service.

Texas

The Dallas County auxiliary held its annual guest day meeting April 5.

Mrs. T. H. Thompson, publicity chairman for the Texas auxiliary, states that each auxiliary in the state has had one or more programs on the "Wagner-Murray-Dingell bill to show the evils of socialized medicine."

Wisconsin

One hundred members of the Milwaukee auxiliary attended the March meeting. Dr. L. J. Van Hecke spoke of the work done in cancer control by the Woman's Field Army, and Dr. E. H. Ryncarson of the Mayo Clinic discussed "Obesity, the Unpopular Subject."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

The Doctor Speaks to the Attorney.—A joint committee composed of three members of the Los Angeles Bar Association and three members of the Los Angeles County Medical Association are arranging a program on the theme "The Doctor Speaks to the Attorney." The series of lectures will begin in September and be concluded in December, covering various medicolegal problems with the medical factors emphasized from the point of view of different specialists. Legal members of the arranging committee are Messrs. F. Murray Keslar, John P. McGinley and Elbert H. Tilson; medical members are Drs. Fred B. Clarke, Long Beach, John Severy Hibben, Pasadena, and Louis J. Regan.

Cancer Prevention Clinic.—A clinic has been opened in Los Angeles to be known as the Cancer Prevention Society. It will be staffed by the Medical Women's Society of Los Angeles County on a voluntary basis and work in cooperation with the Women's Field Army. An announcement indicates that the clinic will be devoted to research. It was stated that "500 non-ailing women" will be asked to sign up for two complete physical examinations a year. No treatment will be given at the clinic, but if a woman is found to have any disease she will be referred to her family physician. Dr. Elizabeth Mason Hohl, educational director of the Women's Field Army in Los Angeles, is in charge of the clinic.

DELAWARE

New Health Commissioner of Wilmington.—Dr. Arthur Parker Hitchens, professor of public health and preventive medicine, University of Pennsylvania School of Medicine, Philadelphia, has been appointed health commissioner of Wilmington, according to *Philadelphia Medicine*.

ILLINOIS

Changes in Health Officers.—Dr. Samuel N. Mallison has been appointed to the new position of superintendent of health of the city of Decatur. Dr. Mallison will be in charge of the public health work of the city and assume much of the work formerly handled by Dr. Pierre A. Steele, city commissioner of public health and safety.

Chicago

Peoples Hospital Closed.—The Chicago Board of Health on July 18 closed the Peoples Hospital because of its insanitary condition and faulty record keeping, newspapers report. It was stated that the procedure was carried out in connection with an investigation by the state's attorney's office of an alleged adoption racket.

Changes on the Faculty at Illinois.—Dr. Raymond B. Allen, dean, University of Illinois College of Medicine, announced July 31 a number of changes on the medical faculty, among others, effective September 1:

Dr. Julius Hays Hess, who has been a member of the faculty for thirty years, retiring on account of age, as professor and head of the department of pediatrics. He will carry the title professor emeritus.

Dr. Henry George Poncher promoted to professor and head of the department of pediatrics to succeed Dr. Hess.

Dr. Milan Vachav Novak to professor and head of the department of bacteriology and public health.

Dr. Yngve Joranson to associate professor emeritus, department of anatomy.

Dr. Aaron Arkin to professor, department of medicine (Rush).

Dr. Richard Leos Jenkins to acting head and associate professor of psychiatry.

Chester William Darrow, Ph.D., to associate professor, department of criminology, social hygiene and medical jurisprudence.

Dr. Norris Julius Heckel, to associate professor, department of surgery.

Dr. John Michael Dorsey to assistant professor, department of surgery (Rush).

Dr. Noah D. Fabricant to assistant professor, department of laryngology, rhinology and otology.

Dr. Edward A. Piszczek to assistant professor, department of bacteriology and public health.

James Clarence Plagge, Ph.D., to assistant professor, department of anatomy.

Dr. John Van Prohaska to assistant professor, department of surgery.

Dr. Anita E. Rapoport to associate and associate anesthetist, department of surgery and Research and Educational Hospital.

Dr. Boris S. Ury to associate, department of psychiatry.

KANSAS

Personal.—Dr. Chester E. Jöss, Topeka, was elected president of the Kansas State Board of Medical Registration and Examination at its meeting in Topeka, June 8, succeeding Dr. Mirl C. Ruble, Parsons, who continues as a member of the board.

Special Society Elections.—Paul Haney, director of the division of sanitation of the Kansas State Board of Health, was chosen president-elect of the Kansas Public Health Association at its annual meeting in Topeka, June 6-8. Leon R. Kramer, D.D.S., director of the dental hygiene division of the state board of health, was installed as president and Dr. James E. Wolfe, Wichita, was named vice president. Miss Jane Taylor, venereal disease control nurse of the state board, is the secretary.—Dr. Clay E. Coburn, Kansas City, was chosen president of the Kansas Tuberculosis and Health Association at its annual meeting, June 6-8, in Topeka. Drs. Frank A. Trump, Ottawa, and Mrs. Mary C. Bure, R.N., Kansas City, are vice presidents. Theo C. Mueller, Topeka, is the treasurer, and Dr. Charles H. Lerrigo the executive secretary. All officers were reelected with the exception of Mrs. Bure.

KENTUCKY

Director of Tuberculosis Control Named.—Dr. Russel E. Teague, Louisville, has been appointed director of tuberculosis control for the Kentucky State Department of Health, succeeding Dr. John B. Floyd, Louisville, who resigned to become medical superintendent of a coal company at Stone, it is reported. Dr. Teague will be succeeded in his position as director of venereal disease control by Dr. Robert H. English, Hopkinsville, acting director of the Christian County department of health.

Silicosis Examining Board Created.—The recent establishment of a permanent medical examining board, paid by the state, to examine all claimants alleged to have become disabled by reason of silicosis has been announced. The board consists of two radiologists and one chest physician, namely Drs. Isaac T. Fugate, Louisville, for a three year term, Charles C. McCoy, Louisville, for two years and Thomas Atchison Frazer, Marion, for one year. The silicosis law in Kentucky was rewritten after a survey by the state department of health, representatives of the Associated Industries of Kentucky, representatives of the two national unions, the insurance carriers and employers groups. The new law is just now going into effect, according to Dr. Walter E. Doyle, Louisville, director of the state bureau of industrial hygiene, July 27. All cases will be referred first of all to the examining board for diagnosis. The results of the board will be referred back to the workmen's compensation board, which operates under the department of industrial relations for action. The law permits a finding of partial permanent disability and also contains a "second injury clause."

MAINE

State Medical Election.—Dr. Adam P. Leighton, Portland, was chosen president-elect of the Maine Medical Association at its annual meeting in Rockland, June 26, and Dr. Raymond V. N. Bliss, Blue Hill, was inducted into the presidency. Dr. Frederick R. Carter, Portland, was reelected secretary.

MICHIGAN

Dr. Ryan Placed in Charge of Rapid Treatment Center.—Dr. Nelson W. Ryan has been assigned by the U. S. Public Health Service to the Michigan Department of Health to be in charge of the venereal disease rapid treatment center opened in June in Ann Arbor (*THE JOURNAL*, May 20, p. 220). Buildings for the center have been made available at the University Hospital. Dr. Ryan, who was in charge of the first rapid treatment center when it opened in South Carolina, has been associated with Dr. Udo J. Wile, professor of dermatology and syphilology at the University of Michigan Medical School, Ann Arbor.

Personal.—Dr. Henri Belanger was honored at a dinner, June 7, by friends and colleagues in recognition of his completion of fifty years in the practice of medicine, all of which time was spent in River Rouge. Dr. Belanger was presented with a gold writing set.—Dr. Edward Sawbridge, who began the practice of medicine at Stephenson in 1883, has retired as agent for the Michigan Bell Telephone Company at Stephenson, a connection he had held since 1890. Newspapers reported

that it was in Dr. Sawbridge's drug store in 1890 that the first telephone instrument was installed at Stephenson.—Dr. and Mrs. David H. O'Donnell, Detroit, celebrated their golden wedding anniversary, June 21.—Dr. Clark D. Brooks, a member of the Detroit Board of Education since 1939, has been elected president of the board.

Typhoid Carriers.—The Michigan Department of Health, Lansing, has under its supervision 290 typhoid carriers. In 1943 11 carriers were released from the department's supervision. One recovered spontaneously, 1 recovered following removal of the gallbladder, 3 moved to other states and 6 died. During 1943 21 new typhoid carriers were identified and placed under supervision; 19 of these were discovered as the source of new cases, while the other 2 were found through convalescent follow-up. No typhoid patient is released from supervision until three specimens, taken a week apart, are free from typhoid germs. Persons who continue to have the germs for a year are considered chronic carriers. In ten years in Michigan only 3 chronic carriers cleared up spontaneously.

Medicine in Survey of Public Opinion.—The Michigan Health Council is conducting a survey of public opinion in Michigan to obtain the attitude of the public toward the medical profession and hospitals, the cost of medical and hospital care, the attitude of the public regarding prepayment health plans under the auspices of professional groups, government or other agencies, and other related matters. The results will be used to formulate a program to educate the public in the type of service being provided by the doctors and doctors' agencies within the state. The Michigan Health Council was organized at a meeting in Mackinac Island, July 16-17, 1943 to act as a clearing house on matters of mutual interest for the Michigan State Medical Society, the Michigan Hospital Association, the Michigan Medical Service and the Michigan Hospital Service. Dr. Andrew S. Brunk, Detroit, is president of the council and Gordon Davis, Detroit, formerly science editor of the *Cleveland Press* and currently in charge of public relations for the Michigan Hospital Service, is the executive secretary. The council has been incorporated and has opened offices at 1402 Washington Boulevard, Detroit.

Proposed School of Industrial Health.—One of the units in the Medical Sciences Center now being developed in connection with the Wayne University College of Medicine, Detroit (*THE JOURNAL*, Oct. 23, 1943, p. 496), is the construction of a School of Industrial Health, it was revealed recently. While the proposed school of industrial health will confine itself to teaching and research, industrial plants will be asked to help support the program on a consultation fee basis. The school will be prepared to undertake certain research projects having to do with industry, but it will be expected that commercial firms asking for this service will finance the costs. The Medical Science Center of Wayne University is a nonprofit corporation organized under the laws of Michigan. Its object is to raise money to build and equip units of the center and to finance programs therein. The physical equipment will become the property of Wayne University, which will operate it. Full authority over curriculum, faculty appointments and program will be retained by the Wayne University administration and the board of education.

MINNESOTA

Medical Art Show.—In a news item in *THE JOURNAL*, July 22, page 859, describing the medical art display of the Minneapolis Public Library, the name of the late Dr. Harry B. Wilmer, Philadelphia, was used instead of that of Dr. Harry A. Wilmer, Baltimore. The names of Capt. Frank H. Netter, M. C., and Mr. Willard C. Shepard were inadvertently omitted from the names of the exhibitors.

MISSISSIPPI

Medical Women Organized.—At a recent meeting in Jackson a group of women organized and chose Dr. Virginia Small, Greenville, as president. The name selected for the new group, which is open to white women in Mississippi holding the degree of doctor of medicine, has been unofficially designated the Medical Women's Club of Mississippi. Other officers of the group include Drs. Virginia F. S. Howard, Jackson, vice president, Margaret Roe Caraway, Gulfport, secretary, and Estelle A. Magiera, Jackson, treasurer. It is planned to hold meetings during the annual session of the Mississippi State Medical Association. The new group hopes to promote a closer association of women physicians of the state socially and professionally.

MISSOURI

New Medical School Librarian.—William A. Fitzgerald, Ph.D., librarian of Brooklyn Preparatory School, Brooklyn, N. Y., has been named to a similar position at St. Louis University School of Medicine, St. Louis, newspapers report. Dr. Fitzgerald has specialized in the history of library science and taught library and social sciences in a number of schools.

Narcotic Violation.—Dr. Joseph A. McNearney, St. Louis, who was arrested at Lexington, Ky., pleaded guilty in the U. S. District Court at Lexington on June 13 to a violation of section 72, title 18, U. S. Code (forging the name of another physician to a narcotic prescription). Dr. McNearney was given a suspended sentence and placed on probation for five years, according to information from the U. S. Bureau of Narcotics.

PENNSYLVANIA

Dr. Sandy Resigns from Mental Health Bureau.—Dr. William C. Sandy, Harrisburg, since 1921 director of the mental health bureau of the Pennsylvania Department of Welfare, has resigned. Dr. Sandy was for a number of years secretary of the American Psychiatric Association.

Dr. Bull Resigns at Lehigh University.—Dr. Raymond C. Bull, organizer and director of the student health service at Lehigh University, Bethlehem, for twenty-one years, has resigned, effective July 1, because of ill health. Dr. Carl O. Keck, assistant to Dr. Bull since 1939, has been named director of the health service.

Philadelphia

Portrait of Dean Pepper.—On July 3 an oil portrait of Dr. William Pepper, dean of the University of Pennsylvania School of Medicine, was unveiled at the Free Library of Philadelphia. Dr. Pepper was president of the board of trustees of the library from 1939 to 1943.

Dr. Babcock Honored.—Dr. William Wayne Babcock, professor emeritus of surgery, Temple University School of Medicine, was recently presented with the Russell H. Conwell Award for "untiring devotion to the advancement of Temple University." The award is a large framed scroll.

Dr. Barnes Heads Biochemical Research at Sharp and Dohme.—Richard H. Barnes, Ph.D., assistant professor of physiologic chemistry, University of Minnesota, Minneapolis, has been appointed head of the department of biochemical research of Sharp and Dohme, Glenolden. He succeeds Dr. Leslie Earle Arnow, who was recently appointed director of research of the company (*THE JOURNAL*, June 3, p. 369).

Health Institute.—The Philadelphia County Medical Society sponsored a health institute at the board of public education, June 26-28. Included among the speakers were:

Dr. Edmund B. Spaeth, Conservation of Sight of School Children.
Dr. Carroll S. Wright, Contagious Skin Conditions Among School Children.
Dr. Frederick H. Allen, Psychiatric Services in the School System.
Dr. Waldo E. Nelson, A Tuberculosis Program in the School System.
Dr. Winthrop M. Phelps, Therapeutics of Cerebrospinal Palsy.
Lieut. Comdr. Joseph F. Hughes (MC), Electroencephalography.

Personal.—Dr. Alfred C. LaBoccett has been appointed superintendent and medical director at the Philadelphia Hospital for Contagious Diseases.—Dr. Harriet L. Hartley, chief of the division of child hygiene, department of health, was recently presented with an award of merit by the Pennsylvania Public Health Association in recognition of her services in the field of public health.—Dr. Charles A. E. Codman has been appointed honorary librarian of the Philadelphia County Medical Society.

Laboratory Named for Levi Hammond.—A laboratory of comparative anatomy in the Pfahler Hall of Science has been named the Levi J. Hammond Laboratory of Comparative Anatomy in honor of the late Dr. Levi J. Hammond. A portrait of Dr. Hammond by Susan has been hung in the main hall. It was unveiled by Mrs. Hammond. Dr. Hammond, formerly president of the Philadelphia County Medical Society, was for many years instructor in aural surgery at the University of Pennsylvania School of Medicine. He died in 1929.

Pittsburgh

George Harris Resigns as Executive Secretary.—Dr. George R. Harris, for nine years executive secretary of the Allegheny County Medical Society, retired June 20 when his term as elected secretary of the society expired. Dr. Norman C. Ochsenhirt was to succeed Dr. Harris in the elective position of secretary, but at the time of this report no one had been named to fill the post of executive secretary.

District Meeting.—The tenth and eleventh councilor districts of the Medical Society of the State of Pennsylvania held a meeting in Pittsburgh, July 20. Among the speakers were

Dr. Francis F. Borzell, Philadelphia, Aims of the Council on Medical Service and Public Relations
Col. Leon J. Genizkow, M. C., Public Health Aspects of Tropical Diseases
Capt. William Blair Mosser (MC), Naval Surgery as of Today
Dr. Lewis T. Buckman, Wilkes Barre, Balanced Personality
Dr. Augustus S. Keck, Altoona, A Challenge to Every Physician
Dr. Paul R. Correll, Easton, The Pennsylvania Medical Practice Act

A feature of the session was the presentation of testimonials to the following members, who have completed fifty years in the practice of medicine: Drs. William Cullen Bryant, Pittsburgh, Herbert P. Crawford, Crafton, George W. Ely, Pittsburgh, William S. Langfitt, Pittsburgh, John F. McNeely, Munhall, Jesse R. Cooper, New Castle, Charles M. Iseman, Ellwood City, John Foster, New Castle, Elizabeth M. McLaughry, New Wilmington, William A. Marsh, Mount Pleasant, Nathaniel E. Sisley, Scottsdale, Charles E. Snyder, Greensburg, and Frank H. Underwood, Monongahela.

TEXAS

University Acquires Convalescent Home.—Mr. and Mrs. Maco Stewart, San Antonio and Galveston, have given their Galveston Island estate to the University of Texas Medical Branch for use as a convalescent home for children. The estate has been named the Margie B. Stewart Convalescent Home for Children. Dr. Arild E. Hansen, professor of pediatrics at the medical school, will direct the medical work at the home and Dr. George W. N. Eggers, clinical professor of orthopedic surgery, the surgical and physical therapy activities. Facilities are available for handling between 30 and 50 convalescent children, with outdoor fresh and salt water pools and special facilities for physical and occupational therapy. The project will comprise a part of the child health program of the University of Texas Medical Branch as supported by the William Buchanan Foundation of Texarkana (THE JOURNAL, February 19, p. 520).

VIRGINIA

Dr. Riggan Reappointed State Health Officer.—Dr. Irl C. Riggan, state health commissioner since 1937, has been reappointed to the office for another four year term.

Robert Hudgens Named Medical Director at Virginia Medical College.—Mr. Robert Smith Hudgens, superintendent, Emory University Hospital, Emory University, Ga., has been appointed medical director of the Medical College of Virginia, Hospital Division, Richmond, effective August 1. He succeeds Dr. Lewis E. Jarrett, who accepted a position as superintendent of Touros Infirmary, New Orleans (THE JOURNAL, May 27, p. 297).

WEST VIRGINIA

Elkins Gives Service in Tornado.—The Davis Memorial Hospital and the staff of the Golden Clinic Elkins, gave complete services, free of charge including X-rays, medication and crutches, to victims of the recent tornado. The OCD blood bank in the hospital served all calls. It is reported that the emergency U. S. Public Health unit sent out a detachment to the Montrose area to function there. Credit is given to Col. O. I. Holeman, commandant of the West Virginia Maneuver Area, for the cooperation he gave during the catastrophe, setting up emergency stations and turning his station hospital to civilian use as necessary while corps men of the medical division assisted in the emergency.

Changes in Health Officers.—Dr. James A. Dolce, health commissioner at Wilmington, Del., has been appointed county health officer at Fairmont, succeeding Dr. Joseph W. Davis, who resigned to join the Baltimore City Health Department. Dr. Herbert Duncan, health officer for district number 2 at Lewisburg, has resigned to accept a residency in eye, ear, nose and throat at the Nashville General Hospital, Nashville, Tenn. Dr. Albert M. Price, Charleston, has resigned as health officer of Kanawha County to enter private practice. Dr. Price was formerly director of the state division of communicable diseases. Dr. Walter J. Riley, health officer for district number 4 at Weston, has been given an indefinite leave of absence on account of ill health.

Activities in State Health Department.—A five member advisory committee, composed of directors of various bureaus, has been set up in the state department of health by Dr. John E. Offner, Weston, state health commissioner. Members who were selected on the basis of seniority will consider personnel problems, interdivisional relationships, intradepartmental poli-

cies, legislative needs, budgeting, departmental morale and merit system qualifications. Members of the committee include J. B. Harrington, B. E., Miss Katherine E. Cox, Miss Laurene C. Fisher, R. N., Dr. Norman G. Angstadt and Dr. Charles S. McKinley. Miss Evelyn Yokum Fortney, vocational home economics teacher at the Shinnston High School, Harrison County, for the past five years, has been appointed nutrition consultant in the division of maternal and child hygiene of the state department of health.

GENERAL

Special Society Election.—Dr. Edward A. Schumann, Philadelphia, was chosen president of the American Gynecological Society at its meeting in Hershey, Pa., in June. Drs. Norris W. Vau, Philadelphia, and James C. Masson, Rochester, Minn., are vice presidents, Dr. Howard C. Taylor Jr., New York, secretary, and Dr. Philip F. Williams, Philadelphia, treasurer.

Officers of Board of Pathology.—Dr. Arthur H. Sanford, Rochester, Minn., was reelected president of the American Board of Pathology at its meeting, June 7-8, in Chicago, and Drs. Frederick H. Lamb, Davenport, Iowa, and Frank W. Hartman, Detroit, were reelected vice president and secretary-treasurer, respectively. Dr. Robert A. Moore, St. Louis, was appointed assistant secretary. Drs. Howard T. Karsner, Cleveland, Alvin G. Foord, Pasadena, Calif., and Roy R. Kracke, Birmingham, Ala., have finished their two terms of service with the board and have been succeeded by Drs. Shields Warren, Boston, James B. McNaught, San Francisco, and Frederick William Sunderman, Philadelphia. Dr. Nathan Chandler Foot, New York, was elected to succeed himself.

Program on Premedical Education.—On September 14, during the annual meeting of the American Association for the Advancement of Science in Cleveland, Alpha Epsilon Delta, a national honorary premedical fraternity, will hold a special program on premedical education. Among the speakers will be Dr. Victor Johnson, Secretary, Council on Medical Education and Hospitals of the American Medical Association, Carlos I. Reed, Ph.D., professor of physiology, University of Illinois College of Medicine, and Hugh E. Scatterfield, Ph.D., premedical adviser, Ohio State University, Columbus, and president of Alpha Epsilon Delta. An informal round table discussion of problems and questions from the audience will follow the talks. It is hoped that this meeting will be the beginning of similar sessions held at various national and regional meetings throughout the country.

Meeting of Obstetricians and Gynecologists.—The American Association of Obstetricians, Gynecologists and Abdominal Surgeons will hold its annual convention at the Homestead, Hot Springs, Va., September 7-9, under the presidency of Dr. Willard R. Cooke, Galveston, Texas. The preliminary program lists the following speakers:

Dr. W. Wayne Babcock, Philadelphia, An Operation for Exstrophy of the Bladder—report of 5 cases
Dr. William S. Bainbridge, New York, Surgery of Uterine Cancer
Dr. Bender Z. Cashman, Pittsburgh, Hysterectomy with Preservation of Ovarian Tissue in the Treatment of Endometriosis
Dr. David P. Findley, Omaha, End Results in the Treatment of Cervicitis
Dr. James R. Goodall, Montreal, Canada, The Defensive Mechanism of the Uterus
Dr. Robert A. Johnston, Houston, Texas, A Critical Analysis of Twenty Two Years Experience with Cesarean Section
Dr. Frederick J. Lynch, Boston, Rupture of the Pregnant Uterus
Dr. Joe V. Meigs, Boston, The Wertheim Operation for Cancer of the Cervix
Drs. William F. Mengerl, Dallas, Texas, and Charles Rodney Stoltz, Iowa City, Total Abdominal Hysterectomy in a Series of 1,921 Patients
Dr. James R. Miller, Hartford, Conn., Repair of Prolapse of the Urethra
Dr. Russell J. Moe, Duluth, Minn., Duplication of Right Kidney Pelvis and Ureter with an Extracavitary Opening
Drs. Robert D. Mussey and Charles R. Mayo, Rochester, Minn., Pregnancy Following Myomectomy
Dr. James F. Norton, Jersey City, N. J., Maternal Mortality—An Analysis Based on More Than Sixty Thousand Births
Dr. Milton G. Potter, Buffalo, Observations of Breech Deliveries in a General Hospital
Dr. Jean P. Pratt, Detroit, Sex Precocity—Report of 4 Cases
Dr. James K. Quigley, Rochester, N. Y., Habitual Abortion
Dr. William A. Scott, Toronto, Canada, Surgical Complications of Pregnancy and Labor

Dr. Cooke will deliver his presidential address on "The Differential Psychology of the American Woman." Dr. Abraham R. Abarbanel, Washington, D. C., will present "The Spasmodic Action of Magnesium Ions on the Tetanically Contracting Human Gravid Uterus," the paper that has been awarded the annual Foundation Prize of the association.

Congress of Physical Therapy.—The American Congress of Physical Therapy will hold its twenty-third annual session at the Hotel Statler, Cleveland, September 6-9, under the presidency of Dr Kristian G Hansson, New York. The program will include an instruction course and, in addition, the following will speak, among others:

Dr Miletus B Jarman, Hot Springs, Va., Mineral Water Therapy
An Appraisal
Dr Louis J Regan, Los Angeles and John S Hubben, Pasadena, Calif., Medical Legal Aspects of Physical Medicine
Dr Carl M Peterson, Secretary Council on Industrial Health, American Medical Association, Chicago, Industrial Rehabilitation
Dr Frank H Ewerhardt, St Louis, A Plea for a More Uniform Terminology
Dr Miland E Knapp, Minneapolis, Education of the Medical Student in Physical Therapy
Basil O Connor, LL D, New York, The Work of the National Foundation for Infantile Paralysis
Dr Donald J Erickson, Rochester, Minn., Physical Therapy in Geriatrics
Capt Charles F Behrens (MC), Activities of the Committee on Rehabilitation of the Baruch Committee
Dr Robert F Dow, Battle Creek, Mich., Treatment of Military Amputees
Dr Arthur L Watkins and Mary A B Brazier, Ph D, Boston, Studies on Muscle Innervation
Dr Robert L Bennett Jr, Warm Springs, Ga., Recognition and Treatment of Common Deformities Found in Convalescent Poliomyelitis

The Ohio chapter of the American Physiotherapy Association will offer a special presentation Thursday. Dr John S Coulter, Chicago, will discuss "A Rehabilitation Center for the Injured Worker" and Catherine Graham, chief physical therapy technician, Mount Sinai Hospital, Cleveland, will give a practical demonstration in walking reeducation. Guest speakers at the annual dinner Thursday evening will be Major General George F Lull, deputy surgeon general, Major General David N W Grant, air surgeon, and Rear Admiral Luther Sheldon Jr (MC). Groups meeting during the annual congress will include the Society of Physical Therapy Physicians, September 6, and the American Registry of Physical Therapy Technicians, September 7.

LATIN AMERICA

Health Activities in Latin America.—*Shipments of Penicillin.*—Shipments of penicillin for treatment of venereal diseases in Puerto Rico have been entirely stopped, according to Dr Ernesto Quintero, San Juan, health department specialist. The report announcing this did not give a reason for the cessation of the shipments.

San Juan Divided Into Zones for Sanitary Improvements.—Dr Antonio Fernos-Isern, commissioner of health, plans to divide the San Juan area into eighteen zones, each zone to be supervised by a local inspector to be in charge of inspecting milk, food and drugs and check up on all sanitary regulations. The plan is a part of a program to increase the efficiency in inspecting and enforcing sanitary regulations in the metropolitan area of San Juan.

Nutrition for Crippled Children.—Crippled children of Puerto Rico are receiving special treatment and diets free through district hospitals and visiting nurse service, it was reported recently.

Society News.—The first Congress of the Mexican Faculties and Schools of Medicine was held in Monterrey City, April 2-7. Resolutions were adopted to permit local government hospitals at the disposal of the medical schools to establish a system of exchange professors at the schools and to establish requirements of the faculties to assist in their recognition as constituents of the National Federation of Medicine, according to *Medicina*.—The first National Congress of Pediatrics of Peru convened in Montevideo, July 4.—The fifth Cuban congress against tuberculosis was held in Santiago, Cuba, in May under the auspices of the National Council of Tuberculosis and the Cuban Society of Phthisiology.

Health in Puerto Rico.—In 1942 there were 32,220 deaths reported for Puerto Rico, giving a crude death rate of 161 per thousand of estimated population as compared with the rate of 186 in 1941. The 1942 rate was the lowest ever reported since the possession was admitted to the registration area in 1932. The seven principal causes of death and their death rates per hundred thousand of estimated population were diarrhea, enteritis and ulceration of the intestine 321, tuberculosis 237.3, pneumonia (all forms) and influenza 143.2, diseases of the heart 108.5, nephritis 95.9, malaria 94.9 and cancer and other malignant tumors 52. This group accounted for 65.6 per cent of all deaths. Eighty-six per cent of the deaths from diarrhea, enteritis and ulceration of the intestine were of infants and children of preschool age. A report from the U S Bureau of Census emphasizes the relatively large number of suicides, particularly in the age group from 15 to 24, in which 183 were recorded, giving a rate of 7. The general

rate was 24.5 per hundred thousand of population. The report says that the suicide problem in Puerto Rico appears to be of about the same order of magnitude as deaths from motor vehicle accidents in the United States.

Scholarships.—Applications for scholarships to study poliomyelitis, cancer and leprosy in the United States through the Alfredo Hirsch Foundation, Buenos Aires, are now being accepted from Argentine physicians. The scholarships are awarded every two years through the Academia Nacional de Medicina of Buenos Aires, Las Heras esq Coronel Diaz, Buenos Aires, from which additional information may be obtained.

Anniversary of Medical School.—On May 10 the Faculty of Medicine of the University of La Plata, La Plata City, Argentina, observed its twenty-fifth anniversary. The school now has about 1,476 students and graduates about 90 annually.

Personal.—Dr Dennis F Recder, Panama City, has been elected president of the Panama Rotary Club for the ensuing year.—Dr Fernando E Triccerri, chief of the department of thoracic surgery of the Rosario University Medical School, Argentina, has gone to the United States to study surgery under a Commonwealth Fund scholarship.—Dr Felipe F Carranza was recently appointed a corresponding member of the Academia de Cirurgia of Rio de Janeiro.

FOREIGN

Sir John Ledingham Retires as Director of Lister Institute.—Sir John C G Ledingham, who retired as director of the Lister Institute of Preventive Medicine, London, has been made professor emeritus of the institute.

Memorial to Cecil Rowntree.—Plans are under way to establish a Cecil Rowntree Medical and Surgical Reference Library at the Queen Victoria Hospital, East Grinstead, in memory of Dr Rowntree, who was honorary surgeon to the hospital for about twenty-five years. According to the *British Medical Journal*, gifts of books or funds will be appreciated to help forward the project.

Personal.—In the king's honor list recently knighthood was bestowed on Dr Alexander Fleming, London, Howard W Florey, Ph D, Oxford, and Percival Hartley, D Sc, Hampstead.—Dr Harry L Parker, a native of Ireland who graduated at the University of Dublin School of Physics, Trinity College, Dublin, in 1918 and who was a member of the Mayo clinic staff from 1925 to 1934, has been elected president of the Royal Academy of Medicine in Ireland and of the Dublin University Biological Association.

Medical Nobel Institute for Research.—The Royal Caroline Institute, Stockholm, in charge of the Nobel Fund for Medicine, has decided to build a Medical Nobel Institute for research in anatomy, biochemistry and physiology, according to *Science*. The institute will consist of three departments in one building to be erected on the premises of the new medical center at Norrbacka in the northwest region of the city. The Biochemical Nobel Institute was founded in 1937 and is directed by Dr Axel Hugo T Theorell. The physiologic department will be a Neurophysiological Research Laboratory, privately endowed in 1940 for Professor Ragnar Granit, who will also be in charge of the new institute. The anatomic department will be associated with a new chair in cell research to be founded for Dr Torbjorn Caspersson.

Russia Provides Premium for Motherhood.—An Associated Press Dispatch from Moscow July 9 announced provisions by the supreme soviet to encourage large families ranging from up to 5,000 rubles, or \$950, at birth of an eleventh child, plus a monthly payment of 300 rubles, or \$57. It was reported that state aid begins with a grant of 400 rubles (\$76) at birth of a third child. A fourth child brings \$247 and \$15.20 per month, with lump sums and monthly aid increasing thereafter. Monthly payments continue until children are 5 years old. A decree issued by the soviet also created honors for mothers, the highest one, "mother heroine," for women rearing 10 or more children, revised family taxes to encourage births, tightened laws against abortionists, liberalized aid for pregnant women and ordered increased production of baby clothes. The order of "Mother's Glory" of first, second and third class will go to women who rear 9, 8 and 7 children. The medal of motherhood first and second class will be presented to women rearing 6 and 5 children. New exemptions for pregnant women include the extension of their leave from work from 63 to 77 days, 35 before birth and 42 afterward. Mothers whose marriages are not registered will receive state relief until the children are 12 years old, and if they want to send the child or children to a state boarding school, this will be done at state expense.

Pathology and the National Health Service

A group of pathologists under the chairmanship of Prof. S. P. Bedson have drawn up a statement on pathology in relation to the proposed national health service—a subject which has not received attention previously. They advocate the closest relationship between academic and applied pathology. The former, mainly concerned with teaching and research, must be centered in the medical departments of the universities, the group believes, but should not be confined to them. The efficiency of laboratories concerned chiefly with routine work can be ensured only if their staffs have an opportunity for independent investigations and benefit by the stimulus of teaching. Hence the staffing of hospital laboratories must be adequate to afford the pathologists time to make use of these opportunities as they arise. Clinical pathology is an important part of a general hospital service but is so closely related to public health bacteriology as to make division unprofitable, it is pointed out.

The university departments of pathology should retain their primary functions of teaching and research and act as training centers for pathologists to supply the needs of the service, the pathologists say. The professors should act as the friends and advisers of the pathologists in their regions and in some cases as national advisers on special subjects and research problems. The public health bacteriologic service can function as a separate administration only at its main centers and even there must be closely associated with the universities and larger hospital laboratories, if only to avoid uneconomic duplications. At the periphery there must be complete fusion. A town serving an area of 100,000 inhabitants cannot support more than one laboratory, it is held. In larger towns the hospital and public health laboratories should be under the same roof, though under separate administration. The clinical laboratories must be situated in hospitals under the disciplinary and financial, but not professional, administration of the owning authorities. Laboratory facilities must be freely at the disposal of the general practitioners in the area, but there should be no isolated, small laboratories staffed only by technicians or by a solitary pathologist. The present hospital laboratories have provided only a skeleton service for the country, the group claims, and a larger number is needed. While the professional freedom of pathologists must be maintained, some central control of the whole service of pathology will have to be exercised if it is to be conceived as one complete section of medical service to the community.

Thiouracil in the Treatment of Thyrotoxicosis

Prof. H. P. Himsworth opened a discussion on thiouracil in the treatment of thyrotoxicosis at the Royal Society of Medicine. Being much safer, thiouracil had replaced thiourea, Professor Himsworth said, though the action of the two is similar. Thiouracil does not produce the vomiting, conjunctivitis or halitosis so commonly found with thiourea, he added. Treatment is in two stages—initial and maintenance. Initial treatment is continued until there is definite regression of signs and symptoms, which takes an average of twenty-nine days, with a dosage of 0.2 Gm. five times a day. All Himsworth's cases showed considerable improvement in this stage and none became drug resistant. The first change was usually disappearance of the skin flush and the last a fall in pulse rate. The average gain in weight was 3.5 Kg. (7 $\frac{7}{10}$ pounds). The basal metabolic rate fell from an average before treatment of +39.7 to +8.6 per cent, while the pulse rate fell from an average of

100 to 80. These improvements occurred in all cases, but other manifestations of improvement were not so consistently apparent. Exophthalmos was seldom diminished, and in most cases there was no reduction in the size of the thyroid. In other words, thiouracil controls only the manifestations of thyrotoxicosis due to the thyroid itself. It acted neither uniformly nor immediately; effects were not usually noticed until after a fortnight's treatment and the maximum effects in about four weeks. For maintenance, the smallest daily dose that would prevent remissions, usually 0.1 to 0.05 Gm., was given. Most of the patients were back at work in three months, Professor Himsworth said.

Toxic manifestations due to overdosage may appear early, when the goiter enlarges, he warned. Later they are insidious and recognizable by fatigue, depression and a bloated appearance. The toxic manifestations of idiosyncrasy are more serious and include fever, rashes, swelling of lymph glands and legs, and blood changes, of which agranulocytosis is the most serious. This proved fatal in 1 case.

A National Maternity Service

The latest manifestation of the trend toward socialization or state control of medical services is a report of the Maternity and Infant Health Services Committee of the Royal College of Obstetricians and Gynecologists, which recommends the formation of a national maternity service that would control all existing services and be controlled by a single administrative authority. Integration is regarded as absolutely essential for efficiency. It is laid down that a maternity service should have three principal aims: to bring the mother safely through pregnancy, labor and the puerperium, to secure the birth of a healthy infant and to leave the mother at the end of her confinement as well as she was when she became pregnant. In the opinion of the committee the fall in maternal mortality is by no means commensurate with the great improvements in medical science. Better use of our medical resources, the committee believes, would still further lower it. It proposes therefore that for purposes of a national service the country should be divided into areas having a population of about a million and yielding about 15,000 births a year and further divided into large "health regions."

In these regions the service would be based on key or primary centers consisting of not less than 100 lying-in beds (at least a third of them to be antepartum), antepartum and other clinics, a department for infants under a pediatrician, laboratories and teaching and research facilities. These key centers would, where possible, be part of a university medical school and have at their head a whole time professional obstetrician. In the areas the service would be based on divisional maternity centers closely associated with key centers. At the periphery would be small local centers. The whole service would act as a single unit with all parts integrated and should be actuated by the principles of continuity, completeness and cooperation.

To overcome the present difficulty, the shortage of a well trained staff, it is suggested that the university centers should be the undergraduate schools and some of the divisional centers the postgraduate schools and schools for midwives. The whole process would have to be evolved gradually until the standard of practice had been considerably raised. General practitioners should take an important share in the national service, but only those with special experience. Some improvements in postpartum treatment are urged. Hospital treatment is seldom required after childbirth, but peace and quiet and freedom from anxiety are essential. Two weeks or more in a postpartum hostel would make all the difference to the health and happiness of mother and child. Good as the work of midwives is, it would be improved by training in large maternity centers, the committee believes.

The Argentine Quintuplets

Some months ago the daily papers announced the birth of quintuplets to a couple in Buenos Aires. The parents of the quintuplets wished to keep information on the matter private. Dr. José A. Beruti, professor of the obstetric clinic of the Faculty of Medicine of the University of Buenos Aires, who investigated the case, found that quintuplets were actually born. The grandmother had had one delivery of triplets and one of twins. A sister and sister-in-law each had two deliveries of twins. A history of twins in the father's family was not determined. Deliveries of single pregnancies during the first and second marriages were spontaneous and normal, and three children from those deliveries are normal. Five years ago the mother had an abortion of triplets at the third month of pregnancy.

During pregnancy and delivery of the quintuplets she was under the care of a midwife. The pregnancy was normal at the beginning. Edema of the legs and the abdomen and severe visual disturbances occurred from the fourth month of pregnancy on. The mother did not stop her daily work as a housewife. The midwife made a diagnosis of twins in the seventh month of pregnancy. In the course of the last month of pregnancy the mother made two excursions of twelve hours each by railroad. According to the midwife, by the end of pregnancy, which went to full term, the abdomen was large; fetal heart beats were "heard in several parts of the abdomen." The symptoms of parturition began on July 14, 1943, when the patient was transferred from her home to the midwife's house. Signs of moderate uterine contraction appeared occasionally on July 15. Subcutaneous administration of 1 cc. of posterior pituitary injection was followed by labor, which started within an hour. The infants were delivered at intervals of ten, twenty, twenty and fifty-five minutes. The bags of water ruptured spontaneously for every fetus except the third one. Delivery was spontaneous in all cases. Vertex presentation and normal delivery of normal infants occurred in 3 cases. Incomplete pelvic presentation and delivery with manual aid (delivery of the arms) occurred in 2 cases. All the infants were eupneic and cried loudly immediately after birth, except the fifth one. This last baby was born in blue asphyxia, but she was treated successfully. Every infant had the proper care and ligation of the cord before the next one was delivered. Two placentas of equal size and weight (700 Gm.) were spontaneously eliminated after delivery of the third and last infants. There were two boys and three girls. The mother had two attacks of lipothymia after delivery of the first and last babies and hypotonia of the uterus before delivering the last baby. A second subcutaneous administration of posterior pituitary injection was done before delivery of the fifth baby. Five hundred cc. of isotonic solution of sodium chloride, injections of proper doses of ergotone and caffeine and stimulants were administered to the mother after parturition. She was put in the Trendelenburg position with an ice bag on the abdomen (uterus). Total duration of delivery was nineteen hours and twenty-five minutes. The amount of eliminated amniotic fluid was about 500 cc. The amount of blood lost was about 1,000 cc. The weight of the infants twenty-four hours after birth was, in order of delivery, 1,300, 1,200, 1,150, 1,500 and 1,250 Gm. (300 Gm. more for the whole group than for the Dionne sisters). The mother never permitted the midwife to call a physician. The puerperium was normal.

The children were not premature. They showed great vitality. On the second day they began to have a mixture of colostrum from the mother, cow's milk and water. The infants were not put in incubators. Oxygen and carbon dioxide were not

administered. The infants were not put in a bath for the first three months of life. The weight of the infants at the age of 8 months and 10 days was 8,800, 8,800, 7,500, 8,400 and 7,500 Gm. They are healthy and beginning to cut teeth.

Interrelation of Hypophysis and Adrenal Glands
Demonstrated by Parabiosis

Drs. B. A. Houssay and R. M. Pinto recently read papers before the members of the Sociedad Argentina de Biología. They said that there is a functional correlation between the anterior part of the hypophysis and the adrenal glands. The former forms and eliminates adrenotropin, which stimulates the cortical functions of the latter and the production of which is regulated by certain substances produced by the adrenal cortex. Removal of the adrenal glands results in an increased production of adrenotropin. The union in parabiosis of a normal rat to another rat which has previously been deprived of the adrenal glands results in the production of adrenal hypertrophy of the normal rat, which hypertrophy is more pronounced if the parabiotic adrenalectomized rat is castrated before adrenalectomy. Sex glands and thyroids have no role in the production of adrenal hypertrophy of parabiotic rats, which is accompanied by increased secretion of hormones which produce atrophy of the thymus. The administration of large doses of desoxicorticosterone to adrenalectomized rats results in regeneration of the adrenal glands, with consequent diminution of the secretion of adrenotropin.

Use of Fish in Antimalarial Crusade

Dr. Alfredo Correas was appointed some time ago by the General Department of Malaria, which is a branch of the Argentine Department of Public Health and Social Assistance, to carry on studies which aimed to find out whether or not autochthonous fishes of the northern section of Argentina are larviphagic. Dr. Correas recently gave his report on the subject. He said that the larviphagic properties of autochthonous fishes of that section of the country are so mild that the fishes are of no value in the antimalarial program. He recommended the transplantation and breeding of voracious larviphagic species, such as gambusia fishes (*schizothorax*) of the southeastern section of the United States; the colisa, macropodus, trichogaster and beta species of the southeastern part of Asia, South Africa, the Nile River and the Congo; and also *Debistes reticulatus* Peters of South America.

Marriages

JOHN JUNIOR THOMPSON, Winona, Minn., to Miss Jewell Stanford of Willard, N. C., in Winston-Salem, N. C., June 24.
JAMES W. REAGAN, Warren, Ohio, to Lieut. Angelyn B. Boezeman of De Motte, Ind., in Fort Custer, Mich., June 1.

WESLEY HARVEY STONEBURNER, Wooster, Ohio, to Miss Mary Elizabeth Banks of Winchester, Tenn., July 3.

ANTHONY F. CARAVELLI, Haddon Heights, N. J., to Miss Olga F. Grellner of University City, Mo., June 29.

LOUIS FABIAN PINE, Burlington, Vt., to Miss Anita Evelyn Du Guay of Worcester, Mass., June 24.

ARTHUR J. HEWETT, Newbury, Mass., to Miss Mary Elizabeth Hogan of West Newbury, June 28.

HALLOWELL DAVIS, Boston, to Miss Florence Eaton of New York in Waterville, Maine, June 29.

JAMES J. MATEJKA JR., Chicago, to Miss Marie Agnes Murphy of Beloit, Wis., June 3.

HARLOW F. BANFIELD, Wellsville, Ohio, to Miss Geneva McCaulla of Springfield, July 8.

FORREST R. MARTIN, Paris, Ill., to Mrs. Cauline McKinney Staley of Decatur, June 20.

WILLIAM HENRY SHULL to Miss Cecelia Day Nuchols, both of Charlotte, N. C., June 1.

Deaths

Robert Morton Smith ♂ West Warwick, R. I.; College of Physicians and Surgeons, Baltimore, 1889; formerly member and president of the state board of health; instrumental in organizing the Kent County Medical Society, serving as its first president; one of the founders of the Pawtuxet Valley Visiting Nurse and Anti-Tuberculosis Association in 1908 and served continuously as chairman of the tuberculosis committee of the association; during World War I an examiner for the local draft board and chairman of the disaster relief unit of Pawtuxet Valley Branch of Providence Chapter, American Red Cross; formerly medical examiner for the State Sanatorium at Wallum Lake; member of the Pawtuxet Valley Chamber of Commerce, Rhode Island Historical Society, National Geographic Society and the Museum of Natural History; died July 10, aged 80, of general arteriosclerosis and cerebral thrombosis.

Clarence James McMullen, Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1912; member of the Illinois State Medical Society; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; served as assistant professor of medicine at Northwestern University Medical School, Chicago, as professor of internal medicine at the Illinois Post-Graduate Medical School and as assistant clinical professor of medicine at Rush Medical College, Chicago; formerly attending physician, Cook County Hospital and the Washington Boulevard hospitals, Chicago, and the City of Chicago Municipal Tuberculosis Sanitarium; died May 24, aged 54, of hypertensive heart disease.

William Edward Nesbit ♂ San Antonio, Texas; Johns Hopkins University School of Medicine, Baltimore, 1913; Army Medical School, 1918; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; chairman of the Procurement and Assignment advisory committee for Bexar County during World War II; served as chairman of the Selective Service System at San Antonio for two years and as civilian examiner at Induction Center, Camp Dodd, since its inception, served during World War I; a charter member of the Texas Club of Internists, of which he had been one of the organizers and past president; on the staffs of the Nix and Santa Rosa hospitals; died April 5, aged 55, of encephalitis.

Joseph Boardman Noble, Waukesha, Wis.; Rush Medical College, Chicago, 1886; member of the State Medical Society of Wisconsin; past president of the Waukesha County Medical Society; at one time owner of a hospital in Tower, Minn.; appointed city physician of Waukesha in 1902; for many years medical examiner for the New York, Mutual, Penn and Northwestern Life Insurance companies, formerly member of the library board and alderman; served as physician for the Wisconsin Industrial School for Boys, for twenty-five years surgeon for the Northwestern Railway; on the staff of the Waukesha Memorial Hospital, where he died May 7, aged 85, of cerebral arteriosclerosis.

Reeve Beecher Howland ♂ Elmira, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1895; past president of the Chemung County Medical Society; in 1897 joined the New York National Guard and served as assistant surgeon with the third New York Volunteer Infantry, assigned to duty in Virginia, during the Spanish-American War; later battalion surgeon and assistant regimental surgeon with the rank of captain; served as medical examiner for the U. S. Army recruiting office; for many years health officer of Elmira; on the staffs of the Arnot-Ogden Memorial and St. Joseph's hospitals; died in New York May 12, aged 74, of coronary thrombosis.

Farrar Cobb, Hyannis, Mass.; Harvard Medical School, Boston, 1893; member of the Massachusetts Medical Society and the New England Surgical Society; fellow of the American College of Surgeons; at one time lecturer on surgery at his alma mater; served on the staff of the Massachusetts General Hospital and as superintendent of the Massachusetts Eye and Ear Infirmary in Boston; chief surgeon from 1930 to 1935 and on the consulting staff from 1930 to 1944 of the Cape Cod Hospital, where he died May 30, aged 77, of cerebral and general arteriosclerosis and uremia.

John Bunyan Acken, Griggstown, N. J.; University of the City of New York Medical Department, New York, 1885; formerly on the staffs of the Blackwell's Island Hospital, the Northwestern Dispensary and Bellevue Hospital in New York; died May 16, aged 88 of chronic myocarditis and arteriosclerosis.

Clifford William Andrews, Waupaca, Wis.; Bennett Medical College, Chicago, 1911; at one time health officer of Beloit; served during World War I; major, medical reserve corps of the U. S. Army, not on active duty; on the staff of the City Hospital; died May 4, aged 62, of coronary thrombosis.

Jabez Eldridge Armstrong ♂ Greenwich, N. Y.; University of Buffalo School of Medicine, 1904; for many years health officer of the town of Greenwich; member of the associate staff of the Mary McClellan Hospital, Cambridge; died June 3, aged 74, of arteriosclerosis and coronary disease.

Charles Harper Baker, Bay City, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882; member and in 1919 president of the Michigan State Medical Society; life member and past president of the Bay County Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Mercy and General hospitals; died July 7, aged 84, of carcinoma of the stomach.

George Edward Baldwin ♂ Green Lake, Wis.; University of the City of New York Medical Department, New York, 1890; an Affiliate Fellow of the American Medical Association; died May 10, aged 78, of coronary thrombosis, cardiorenal disease and hypertension.

John Henry Becker Jr., Port Jefferson Station, N. Y.; Long Island College Hospital, Brooklyn, 1907; died April 25 of cerebral hemorrhage, hypertension and arteriosclerosis.

Pierre Bergeron, Manchester, N. H.; Laval University Faculty of Medicine, Quebec, Que., Canada, 1904; member of the New Hampshire Medical Society; served during World War I; died May 7, aged 62, of chronic myocarditis, myocardial decompensation and coronary thrombosis.

Thackery Louis Berry, Frankfort, Ky.; Meharry Medical College, Nashville, Tenn., 1915; died June 7, aged 54.

Walter Day Biggs, Lometa, Texas (licensed in Texas by years of practice); health officer; died May 11, aged 71, of carcinoma of the throat.

Harry Bock, Ossining, N. Y.; Bellevue Hospital Medical College, New York, 1898; died April 10 of generalized arteriosclerosis.

John C. Boyle, Medical Lake, Wash.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; assistant superintendent and later assistant physician of the Eastern State Hospital; died May 7, aged 66.

Charles Edward Brain, Salt Lake City; Jefferson Medical College of Philadelphia, 1910; member of the Utah State Medical Association; served during World War I; member of the senior staff, St. Mark's Hospital; died June 4, aged 57, of coronary occlusion due to coronary sclerosis.

Jennie Nicholson Browne, Baltimore; Woman's Medical College of Baltimore, 1902; formerly professor of physiology at her alma mater; died June 21, aged 68, of coronary occlusion, chronic myocarditis and arteriosclerosis.

John Harold Buffum ♂ Wallingford, Conn.; University of Vermont College of Medicine, Burlington, 1898; died in the Meriden Hospital, Meriden, May 28, aged 69, of pneumonia.

Ervin M. Campbell, Ferriday, La.; Memphis (Tenn.) Hospital Medical College, 1906; served as coroner; died May 16, aged 68, of myocarditis.

Quinn C. Cantrell, McMinnville, Tenn.; University of Tennessee Medical Department, Nashville, 1908; for many years health officer of Warren County; died June 7, aged 64, of cerebral hemorrhage.

Benjamin Franklin Chambers, Port Arthur, Texas; Memphis (Tenn.) Hospital Medical College, 1901; member of the State Medical Association of Texas; on the staff of St. Mary's Hospital, Gates Memorial; died May 18, aged 70, of myeloma.

William Levi Clark, Hoosick, N. Y.; University of Vermont College of Medicine, Burlington, 1885; member of the Medical Society of the State of New York; served in the medical corps of the U. S. Army during World War I; served as health officer of Hoosick; died in a hospital at Albany June 16, aged 80.

Marsden Treutlen Cleckley, Augusta, Ga.; Hahnemann Medical College and Hospital of Philadelphia, 1895; died May 8, aged 73.

Edward Moody Cook ♂ York Harbor, Me.; Harvard Medical School, Boston, 1924; diplomate of the National Board of Medical Examiners; served overseas during World War I; died in May, aged 44, of periarthritis nodosa.

Orris Graem Cruikshank, Terre Haute, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1898; surgeon for the Chicago, Milwaukee and St. Paul Railroad; died June 17, aged 83, of cerebral hemorrhage.

George Washington Götter, Prescott, Ariz.; Harvard Medical School, Boston, 1892; died June 3, aged 78.

Homer J. Davidson Ⓢ Seattle; Johns Hopkins University School of Medicine, Baltimore, 1905; fellow of the American College of Surgeons; on the staffs of the Swedish Hospital and the Columbus Hospital, where he died May 28, aged 66, of uremia.

Lafayette Millard Davis, Roanoke, Va.; Kentucky School of Medicine, Louisville, 1904; medical examiner for the Norfolk and Western Railway Company; died May 6, aged 62.

Harry W. Dechert, Orwigsburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; served on the staff of the Pottsville Hospital, Pottsville; for many years examining physician for the Reading Railroad; died in the Schuylkill County Hospital, Schuylkill Haven, May 29, aged 71, of diabetes mellitus, arthritis and disease of the prostate.

Robert W. Dixon, Dixon, Ky.; Kentucky School of Medicine, Louisville, 1896; died May 29, aged 74.

Michael Joseph Dowd Ⓢ Thompsonville, Conn.; Baltimore Medical College, 1901; examiner for the Metropolitan Life Insurance Company for many years; served as examiner for the Connecticut State Boxing Commission; on the staff of the Mercy Hospital, Springfield, Mass., where he died April 4, aged 75, of prostatitis and acute cardiac failure.

Sylvester A. J. Ennis Ⓢ Shullsburg, Wis.; Milwaukee Medical College, 1910; president of the LaFayette County Medical Society; served during World War I; owner of Dr. Ennis' Hospital; organizer of the LaFayette County Tuberculosis Clinic at Darlington; surgeon for the Chicago, Milwaukee and St. Paul Railway; president of the Shullsburg Park Commission since the park was established; died in the Wisconsin General Hospital, Madison, May 19, aged 58, of arteriosclerotic heart disease.

Samuel Clyde Fittz, Winnfield, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1907; member of the Louisiana State Medical Society; served as parish coroner; medical examiner for Winn Parish Selective Service Board during World War I and II; senior member of the Fittz-Faith Clinic; died May 14, aged 63.

Maurice Monroe Fleagle, Hanover, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1896; past president of the board of health; on the staff of the Hanover General Hospital; died May 30, aged 72, of coronary thrombosis.

Andrew H. Frankel, Chicago; Wisconsin College of Physicians and Surgeons, Milwaukee, 1906; senior lieutenant in the U. S. Naval Reserve during World War I, serving later with the same rank in the regular navy; on the staffs of the American and John B. Murphy hospitals; died May 29, aged 61, of cerebral hemorrhage, arteriosclerosis and chronic nephritis.

Robert Lionel Gordon, Woodside, La.; Tulane University of Louisiana School of Medicine, New Orleans, 1922; member of the Louisiana State Medical Society and the American Urological Association; served an internship at the U. S. Marine Hospital number 14 in New Orleans; on the staffs of Hotel Dieu, Mercy, Baptist and French hospitals, New Orleans, serving at one time as president of the staff of the last; died May 5, aged 44, of diabetes mellitus and coronary thrombosis.

Middleton Howard Hagood Ⓢ Brewton, Ala.; Medical College of Alabama, Mobile, 1898; for many years secretary of the Escambia County Medical Society; served in France during World War I; member of the board of education; died in a hospital at Montgomery May 21, aged 70, of coronary occlusion.

Charles Huse Hale, Boswell, Okla.; Kentucky School of Medicine, Louisville, 1908; member of the Oklahoma State Medical Association; served as president of the Choctaw County Medical Society; examiner for the Frisco Railroad; died April 25, aged 70, of heart disease.

Frederick A. Hayes, Buffalo; Niagara University Medical Department, Buffalo, 1892; member of the Medical Society of the State of New York; died April 30, aged 78, of coronary sclerosis and arteriosclerotic heart disease.

Arthur Hebb, Baltimore; Baltimore Medical College, 1898; member of the Medical and Chirurgical Faculty of Maryland;

served on the staff of the Johns Hopkins Hospital; died April 24, aged 66, of hypostatic pneumonia, cerebral thrombosis, general arteriosclerosis and diabetes mellitus.

James Burch Joyce, Baltimore; University of Maryland School of Medicine, Baltimore, 1894; formerly member of the city health department; died May 21, aged 72, of subarachnoid hemorrhage and hypertensive cardiovascular disease.

Benjamin Edward Kaplan, Newark, N. J.; University and Bellevue Hospital Medical College, New York, 1905; died May 21, aged 60, of coronary thrombosis and arteriosclerotic heart disease.

Andrew Edward Kepert, Calumet City, Ill.; Jenner Medical College, Chicago, 1905; also a pharmacist; died in St. Margaret Hospital, Hammond, Ind., May 26, aged 65, of carcinoma of the liver.

John Jay Kinney, Wooster, Ohio; University of Wooster Medical Department, Cleveland, 1889; member of the Ohio State Medical Association; on the staff of the Community Hospital, formerly known as the Kinney Hospital, of which he had been the founder, and physician in charge of the Kinney-Knestrick Hospital and the Kinney Memorial Emergency Hospital; died in the Flagler Hospital, St. Augustine, Fla., May 14, aged 79, of coronary thrombosis.

Harry Wadsworth Long Ⓢ Escanaba, Mich.; Northwestern University Medical School, Chicago, 1900; served during World War I; on the staff of St. Francis Hospital; died May 30, aged 65, of coronary thrombosis.

William J. McKown, Albany, N. Y.; Albany Medical College, 1894; member of the Medical Society of the State of New York; a captain in the New York National Guard from 1905 to 1911; on the staff of the Memorial Hospital; died May 23, aged 72, of carcinoma of the throat.

Orville Bruce Moon Ⓢ Bisbee, Ariz.; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; city and county health officer; for many years a member of the staff of the Copper Queen Hospital; member and past president of the Kiwanis Club; died in Warren May 22, aged 54, of coronary thrombosis.

Charles Arthur Mooney, Ferndale, Mich.; University of Michigan Medical School, Ann Arbor, 1916; member of the Michigan State Medical Society; first lieutenant in the medical corps of the U. S. Army during World War I; health officer of Ferndale; a member of the board of trustees of the Oakland County Tuberculosis Sanatorium, Pontiac, from 1938 to 1940, when he became chairman of the board; on the staff of the Mount Carmel Mercy Hospital, Detroit, where he died May 30, aged 54, of pneumonia and heart disease.

Joseph Sauter Muller, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1905; member of the Louisiana State Medical Society; served with the U. S. Immigration Service during World War I; died in the Hotel Dieu, Sisters' Hospital May 19, aged 60, of acute myocarditis.

Frank Edward Murphy, St. Louis; St. Louis University School of Medicine, 1920; died in the Missouri Baptist Hospital May 18, aged 51, of lobar pneumonia.

John H. Neary, Detroit; Michigan College of Medicine and Surgery, Detroit, 1900; member of the Michigan State Medical Society; active in the founding and on the staff of St. Joseph's Mercy Hospital, where he died May 21, aged 68; of cardiac failure and carcinoma of the sigmoid.

Martin Landis Nissley Ⓢ Hummelstown, Pa.; Medico-Chirurgical College of Philadelphia, 1905; for many years member and president of the school board; served as director and president of the Hummelstown National Bank; president of the Hummelstown Mutual Fire Insurance Company; physician for the Paxtang draft board during World War I; medical superintendent of the Dauphin County Hospital, Harrisburg; died May 26, aged 62, of heart disease.

James Albert Northeross, Chicago; Meharry Medical College, Nashville, Tenn., 1919; found drowned May 27, aged 54.

John Hanly O'Connell Ⓢ Topeka, Kan.; St. Louis University School of Medicine, 1909; treasurer and past president of the Kansas Medical Society; served during World War I; on the staffs of Christ's Hospital, St. Francis Hospital and the Stormont Hospital, where he died May 22, aged 59, of coronary thrombosis and arteriosclerosis.

Carolyn L. Olendorf Ⓢ Cobleskill, N. Y.; Woman's Medical College of Pennsylvania, Philadelphia, 1899; died May 23, aged 69, of cerebral hemorrhage.

Walter Peter Prudhomme, Pineville, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1906; member of the Louisiana State Medical Society; served overseas during World War I; served on the staff of the Central Louisiana State Hospital; died April 4, aged 62.

Bert E. Purell \oplus Iowa Falls, Iowa; State University of Iowa College of Medicine, Iowa City, 1898; member of the city council; died May 15, aged 70, of coronary occlusion.

John Willard Robinson, Grand Rivers, Ky.; Kentucky School of Medicine, Louisville, 1897; member of the Kentucky State Medical Association; died June 1, aged 78, of cirrhosis of the liver.

Samuel Theodore Roeder Jr., Baltimore; University of Maryland School of Medicine, Baltimore, 1891; died April 26, aged 75, of chronic myocarditis, nephritis and arteriosclerosis.

Rupert Reed Rogers, Warren, Ohio; Columbia University College of Physicians and Surgeons, New York, 1914; member of the Ohio State Medical Association and the American Academy of Pediatrics; a member of the staff of the Warren City Hospital; died April 20, aged 56, of multiple myeloma.

William Frederick Saybolt, Forest Hills, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; member of the Medical Society of the state of New York; fellow of the American College of Surgeons; served on the staffs of the Mary Immaculate Hospital, Jamaica, St. Catherine's and the Lutheran hospitals, Brooklyn, and the Doctors Hospital, New York; died in St. Francis Hospital, Port Jervis, June 20, aged 65.

Charles Edward Schoff \oplus Sacramento, Calif.; Cooper Medical College, San Francisco, 1908; specialist certified by the American Board of Dermatology and Syphilology; member of the state board of medical examiners from 1929 to 1940; served on the staffs of the Sacramento County and Sutter General hospitals; died May 28, aged 59, of cerebral embolism.

Winthrop Davis Seudder, West Hartford, Conn.; Harvard Medical School, Boston, 1920; member of the Connecticut State Medical Society; specialist certified by the American Board of Surgery; fellow of the American College of Surgeons; on the staff of the Hartford Hospital, Hartford; died in the New England Deaconess Hospital, Boston, May 13, aged 50, of glioblastoma multiforme of one cerebral hemisphere.

Edwin J. Siegmund, Wabash, Ind.; Chicago Homeopathic Medical College, 1901; served as health officer of Wabash County and as school doctor; died May 25, aged 68, of heart disease.

Albert French Storke, Oak Park, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1890; member of the Illinois State Medical Society; formerly health officer of Oak Park and secretary of the department of health; died in the West Suburban Hospital May 28, aged 75, of chronic myocarditis and cerebral embolism.

Clifford William Walden, Beatrice, Neb.; John A. Creighton Medical College, Omaha, 1896; died in the Bishop Clarkson Memorial Hospital, Omaha, May 11, aged 67, of pneumonia.

Silas Anderson Walker, La Follette, Tenn.; Tennessee Medical College, Knoxville, 1894; died in a Knoxville hospital May 21, aged 79, of cerebral hemorrhage.

Samuel Arthur Watts, Marlin, Texas; Medical Department of Grant University, Chattanooga, Tenn., 1902; member of the State Medical Association of Texas; urologist, Torbett Clinic and Hospital; died April 21, aged 69, of chronic bronchitis and acute pneumonia.

Karl Robert Werndorff, Council Bluffs, Iowa; Medizinische Fakultät der Universität Wien, Austria, 1902; member of the Iowa State Medical Society, Clinical Orthopedic Society and the American Academy of Orthopaedic Surgeons; fellow of the American College of Surgeons; on the staff of the Jennie Edmundson Memorial Hospital; died May 28, aged 66, of coronary thrombosis.

Lyle Livingstone Wyse, Hamburg, N. Y.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1931; member of the Medical Society of the State of New York; interned at the Toronto General Hospital and the Hospital for Sick Children in Toronto; served as resident in otology, laryngology and rhinology at the Buffalo General Hospital; on the staffs of Our Lady of Victory Hospital in Lackawanna, Buffalo General, Children's and Mercy hospitals in Buffalo; died May 21, aged 38, of coronary occlusion.

DIED WHILE IN MILITARY SERVICE

Frederick Henry Dieterich \oplus Miami, Fla.; Columbia University College of Physicians and Surgeons, New York, 1910; specialist certified by the American Board of Pathology, Inc.; formerly on duty at the Peking Union Medical College, Peking, China; served as an instructor in surgery at his alma mater, director of pathology at the Creighton University Medical School, Omaha, and later served at the Rockefeller Institute in New York; formerly professor of pathology at the Medical College of the State of South Carolina, Charleston, where he had been consultant pathologist at the State Hospital; formerly director of laboratories at the Good Samaritan Hospital, Cincinnati, and on the staffs of the James M. Jackson Memorial Hospital, Miami, and St. Francis Hospital, Miami Beach; formerly pathologist for the department of welfare in New York City and director of bureau of laboratories, department of public health at Yonkers, N. Y.; served during World War I; commissioned a major in the medical corps, Army of the United States, on April 28, 1942; U. S. Army laboratory officer at the AAF Regional Station Hospital, Barksdale Field, La., where he died February 16, aged 56, of coronary occlusion.

Roland Nikolaus Klemmer \oplus Lancaster, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1922; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Internal Medicine; member of the American Heart Association; fellow of the American College of Physicians; served as chief of the medical staff, Lancaster General Hospital; commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve on Aug. 11, 1941 and began active duty on Dec. 29, 1941; later promoted to commander; died aboard ship in the Pacific area May 9, aged 46, of chronic myocarditis.

Leo Hartney McMahon \oplus Breckenridge, Minn.; St. Louis University School of Medicine, 1925; served on the staff of St. Francis Hospital; commissioned a lieutenant commander in the medical corps of the U. S. Naval Reserve on Nov. 18, 1943; a medical officer at the Great Lakes Naval Training Center, Great Lakes, Ill.; died in Waukegan, Ill., May 29, aged 42.

Ross Mayberry Newman \oplus Kansas City, Mo.; Washington University School of Medicine, St. Louis, 1931; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; assistant in surgery at the University of Kansas School of Medicine, Kansas City, Kan.; attending surgeon in urology at the Kansas City General Hospital; chairman of the department of urology, St. Joseph Hospital; member of the executive staff in urology at the Research Hospital; member of the visiting staff in urology at St. Luke's Hospital and St. Mary's Hospital; on May 22, 1942 commissioned a captain in the medical corps, Army of the United States, beginning extended active duty on May 31, 1942; later promoted to major; died in Chicago June 10, aged 38.

John Joseph Whoriskey Jr., Cambridge, Mass.; Tufts College Medical School, Boston, 1942; diplomate of the National Board of Medical Examiners; served an internship at the Newton Hospital, Newton; first lieutenant, medical corps, Army of the United States; died on board ship en route to the American area April 13, aged 26.

Robert James Wilson \oplus Lieutenant Colonel, M. C., U. S. Army, Buffalo; University of Buffalo School of Medicine, 1931; Army Medical School, 1933; commissioned a first lieutenant in the medical reserve corps of the U. S. Army in 1931; entered the medical corps of the U. S. Army in 1932; promoted to captain in 1934, major on July 1, 1943 and later to lieutenant colonel; interned at the Walter Reed General Hospital, Washington, D. C., where he served as assistant chief ward officer in the surgical service; later assigned to the Army and Navy General Hospital at Hot Springs National Park, Ark.; in 1941 became associated with the Office of the Surgeon General Finance and Supply Division; later chief of the Civilian Personnel Division; staff officer of the U. S. Army Bruns General Hospital, Sante Fe, N. M., where he died July 1, aged 38.

Bureau of Investigation

STIPULATIONS

Agreements Between Federal Trade Commission and Promoters of Various Products

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products.

Black-Draught, Syrup of Black-Draught and Black Draught (Granulated)—That these preparations contain a tonic, help to tone lazy intestinal muscles or the digestive system, or have any effect on a sallow complexion were misrepresentations which the Chattanooga Medicine Company and Nelson Chesnut Company, an advertising agency, both of Chattanooga, Tenn., agreed to eliminate from the advertising, in a stipulation that they entered into with the Federal Trade Commission in August 1943. They agreed, further, not to publish any advertisement which fails to reveal that these products should not be used when abdominal pain, nausea, vomiting or other symptoms of appendicitis are present, provided, however, that such advertisement need only contain the statement, "Caution Use only as directed if the label instructions for use bear a warning to the same effect."

Crysta-Jell and Reducers Skin Lotion—These are put out by Eugene Schiff, trading as Schiff Bio Food Products, Detroit. In September 1943 he entered into a stipulation with the Federal Trade Commission in which he agreed to discontinue the following advertising misrepresentations: That Crysta-Jell will restore energy or health, preserve health, youth or appearance, cure obesity, satisfy hunger, or effect a loss of 3 to 4 pounds of weight per week or in any other definitely stated amount within any given period of time, that it contains no drugs or chemicals, that it is a vegetable gelatin compound or a vegetable compound or that Reducers Skin Lotion will keep the skin firm.

Hanovia Alpine Sun Lamp—The Hanovia Chemical & Manufacturing Company, Newark, N. J., entered into a stipulation with the Federal Trade Commission in September 1943 in which it agreed to discontinue the following misrepresentations in the sale of this device: That the rays from the lamp are equivalent to those of the sun in physical or therapeutic properties, and that through its use a person may enjoy all the health giving benefits of sunshine, that because of its quartz burner the lamp possesses all the healing and tonic qualities of ultraviolet lamps, that the use of the lamp will clear the complexion of blemishes, build resistance against colds and disease, assure sound teeth, stabilize the nerves, kill bacteria, shorten a period of convalescence, and be an indispensable means to beauty, and that it is endorsed by the medical profession the world over for unsupervised home treatment. The concern further stipulated that it would discontinue any advertisement or trade literature which failed to reveal clearly that exposure to the lamp with respect to either proximity or length of time may result in injury to the user, that the device should not be used in cases of pellagra, lupus erythematosus, or certain types of eczema, and that it should never be used unless goggles are worn to protect the eyes. The stipulation provided, however, that such advertising need contain only the statement, "Caution Use only as directed" when the directions on the label include a warning to the same effect.

Histeen Tablets—On Aug. 23, 1943, the Histex Corporation, Chicago, entered into a stipulation with the Federal Trade Commission, agreeing to discontinue any advertisement which did not reveal that Histeen Tablets should not be taken by persons having heart or kidney ailments, except on competent medical advice, and that the product may cause serious blood disturbances if taken frequently or continuously. It was provided, however, that such advertisements need contain only the statement, "Caution Use only as directed if the directions for use contain a warning to the same effect." This preparation is sold as a hay fever treatment, and an earlier stipulation was entered into in February 1938 by the promoters, in which they agreed to discontinue representing that Histeen will give relief for hay fever sufferers in a radically different way, that it works like magic and eliminates every trace of hay fever suffering for an entire season, that it is the fastest acting cold remedy and will relieve other miseries unless this latter claim is qualified so as to show the therapeutic limitations of the product.

Mistol Drops and Mistol Drops with Ephedrine—In September 1943 Stanco Incorporated, New York, which puts out these products, and McCann Erickson, Inc., which handles the advertising, stipulated with the Federal Trade Commission to discontinue any advertisements which failed to reveal that the preparations should not be administered to undernourished infants, abnormally weak children or debilitated elderly persons, that frequent or excessive use of Mistol Drops should be avoided and that such use in the case of the other Mistol product might cause nervousness, restlessness or sleeplessness, and that persons suffering from high blood pressure, heart disease, diabetes or thyroid trouble should

not use the ephedrine product except on competent advice. The stipulation provided, however, that such advertising need contain only the statement, "Caution Use only as directed" if and when the directions for use are given on the label and carry a warning to the same effect.

Pomade Gonzalez—This is put out by one Espiridion Gonzalez, Laredo, Texas, who stipulated with the Federal Trade Commission in August 1943 that he would cease representing that the product may give excellent results in cases of ringworm, warts or skin sores, or will remove all kinds of skin eruptions. He further agreed to discontinue any advertisements which failed to reveal that the Pomade contains 50 per cent of salicylic acid and that a product of this strength, when repeatedly applied to the skin (other than two or three applications for hard corns and calluses) will cause local irritation. It was provided, however, that such advertisements need only contain the statement, "Caution Use only as directed" if the label directions bear a warning to the same effect.

Posture-Aid—This alleged health device is put out by J. W. Cole, trading as Posture Aid Company, Dallas, Texas. In August 1943 Cole, with John and Evelyn Brough, who conduct the agency handling the Posture Aid advertising, stipulated with the Federal Trade Commission that they would discontinue the following advertising misrepresentations: That the device relieves constipation, headache, backache, nervousness, fatigue or tenseness, pulls muscles into place, relaxes or strengthens them, relieves tired or cramped muscles or trains them to hold the body erect, corrects misplaced vertebrae, double chin, round shoulders, swayback or flat chest, lifts the chest or gives greater room for lung expansion, flattens the stomach, promotes health, appetite, well being, new energy, beauty of figure or improved posture, exercises the muscles of the neck or tones, relaxes, straightens or stretches the spine.

S P S Scalp Food—In August 1943 Samuel P. Shokunbi, trading as the S P S Chemical Company, Chicago, entered into a stipulation with the Federal Trade Commission in which he agreed to discontinue the following advertising misrepresentations: That the product will feed or nourish the scalp, promote the growth or improve the grade of hair, or be a cure or remedy for itching scalp eczema, conditions which cause falling hair or dandruff, except in so far as its use will facilitate the mechanical removal of loose scales of dandruff. The respondent further agreed to cease representing, through the use of the term "Scalp Food" or any other expression of similar meaning, that the product will feed or nourish the scalp.

Vita Fluff, Lovih and Glamour—These are put out by Donald H. and Matilda Miller, trading as Northern Research Industries, Dayton, Ohio. In a stipulation which they entered into with the Federal Trade Commission in August 1943, they agreed to discontinue the following advertising misrepresentations: That Vita Fluff adds natural sheen or any sheen or luster to the hair, that Lovih is not similar to Vita Fluff, and that the two are not identical, except for a small content of synthetic oil added to Lovih, that Lovih creates a true sheen which will last indefinitely or for any longer time than that produced by ordinary oil shampoos that Glamour is made from actual lemon, or that, as an acid free product, it may be relied on to accomplish results equivalent to those obtained from a lemon rinse. They further agreed to discontinue any statements to the effect that nonlathering oil shampoos do not rinse out of the hair, that they have little, if any, cleansing action and will not cleanse the hair or alter the natural stretch of human hair, and to cease making any other unwarranted statement which might tend to disparage or discredit competitors or their products. Further, they agreed to discontinue use of the trade designation "Northern Research Industries" for their business, or the word "Research," either alone or in combination with other words, in any manner that might give the impression that their business is a research undertaking.

Wade's Wonder Worker—That this product will remove corns or calluses instantly or afford immediate relief from them, or that it contains ingredients not found in other preparations and is an effective treatment for bunions, chilblains, ingrowing nails, warts, rusty nail wounds, poison oak, or all skin diseases and disorders, is an adequate treatment for all deep-seated cases of athlete's foot or ringworm, or for bites or stings of poisonous insects or can be depended on to relieve all types of toothache were misrepresentations which Claren Richard Wade, trading as C. R. Wade Medicine Company, Hot Springs, Ark., agreed to remove from his advertising in a stipulation that he entered into with the Federal Trade Commission in August 1943. He further stipulated to discontinue any advertisement which did not clearly reveal the potential danger in using the product. It was provided, however, that if the directions for use, whether appearing in or on the labeling, contain adequate and specific warnings as to the potential danger, the advertisement need bear only the statement, "Caution Use only as directed."

Western Medical Corporation's Treatment—This has been promoted for years to the public, chiefly by mail. In May 1943 the Federal Trade Commission reported that it had accepted a stipulation from the Western Medical Corporation of Chicago, in which the latter agreed to discontinue the following misrepresentations: That the method of treatment it offers for epilepsy is new or uncommon and that methods followed in general are "old fashioned," that its method of treatment will "do something more" than simply hold down epileptic attacks or that it may be expected to reach and treat the underlying causes of such attacks, that the cases of epilepsy are usually known to the physician employed by the Western Medical Corporation and that in general such cases are inherited, but that diseases from ancestral disorders or diseases, injury, fright, overexertion, a permanent weakening of the system by such ailments as glandular diseases, typhoid, influenza and pneumonia, and that from written answers to questionnaires the respondent corporation can obtain sufficient information for the adequate and effective treatment of epilepsy.

case of epilepsy. According to the Commission, the preparations sold by the respondent contained such drugs as thyroid extract, zinc phosphide, bromides, laxatives or phenobarbital, which, the stipulation states, are dangerous to health if used in too frequent or too large doses or for extended periods of time. The corporation agreed to discontinue any advertising which failed clearly to reveal that such ingredients are potentially dangerous to the health of the user. It was provided, however, that it would be sufficient for the advertising to warn: "Caution, Use Only as Directed" when the directions on the labels contained an adequate and specific warning as to the potential dangers mentioned above.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the Examining Boards in Specialties were published in THE JOURNAL, July 29, page 931.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, Oct. 24-26. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery.

ALASKA: Juneau, September 5. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

DELAWARE: Dover, Oct. 10-12. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: * Washington, November. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

INDIANA: Indianapolis, Jan. 3-5. Exec. Sec., Board of Medical Registration and Examination, Miss Ruth V. Kirk, 301 State House, Indianapolis 4.

IOWA: * Iowa City, Sept. 25-27. Dir. Division of Licensure and Registration, Mr. H. W. Greif, Capitol Bldg., Des Moines.

KANSAS: Nov. 2-3. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City.

KENTUCKY: Louisville, Sept. 11-12. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville.

LOUISIANA: Sept. 7-9. Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

MINNESOTA: * Minneapolis, Aug. 29-31. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul.

MISSOURI: St. Louis, Sept. 18-20. Sec., State Board of Health, Dr. James Stewart, Smt Capitol Bldg., Jefferson City.

MONTANA: Helena, Oct. 2-4. Sec., Dr. O. G. Klein, First Nat'l Bank Bldg., Helena.

NEBRASKA: * Omaha, Sept. 26-28. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Bldg., Lincoln.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. D. G. Smith, 77 Main St., Nashua.

NEW MEXICO: * Santa Fe, Oct. 9-10. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.

NORTH CAROLINA: Raleigh, Sept. 11-12. Sec., Dr. W. D. James, Hamlet.

OHIO: Examination. Columbus, Sept. 26-29. Endorsement. Columbus, Oct. 3. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA: * Oklahoma City, Sept. 16. Sec., Dr. J. D. Oshorn, Jr., Frederick.

SOUTH CAROLINA: Charleston, Sept. 11-13. Sec., Dr. N. B. Heyward, 1329 Blandena St., Columbia.

UTAH: Salt Lake City, Sept. 20-22. Asst. Dir., Department of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

VERMONT: Burlington, Sept. 12-14. Sec., Dr. F. J. Lawless, Richford.

VIRGINIA: Richmond, Sept. 19-22. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WEST VIRGINIA: Charleston, Oct. 2-4. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

DISTRICT OF COLUMBIA: Washington, October. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.

FLORIDA: Gainesville, Nov. 4. Final date for filing application is Oct. 20. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.

MICHIGAN: Ann Arbor and Detroit, Oct. 13-14. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

OREGON: Portland, Nov. 4. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, Aug. 16. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

WISCONSIN: Madison, Sept. 23. Sec., Prof. R. N. Bauer, 152 W. Wisconsin Ave., Milwaukee 3.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Federal Food, Drug and Cosmetic Act: Marmola Tablets for Obesity Misbranded.—The United States filed a libel in the federal district court, western district, Wisconsin, for the condemnation of a shipment in interstate commerce of Marmola Prescription Tablets, marketed as a cure for obesity, on the ground that the preparation was misbranded within the meaning of the Federal Food, Drug and Cosmetic Act. The Raladam Company, which marketed the preparation to wholesale and retail outlets, intervened in the proceedings. The trial court ordered that a decree of condemnation issue (*United States v. 62 Packages More or Less, of Marmola Prescription Tablets*, 48 F. Supp. 878; J. A. M. A. 122:702 [July 3] 1943) and the Raladam Company appealed to the circuit court of appeals, seventh circuit.

The libel filed by the federal government alleged that the preparation was misbranded within the meaning of the Federal Food, Drug and Cosmetic Act because (1) it was dangerous to health when used in the dosage or with the frequency prescribed in its labeling and (2) the labeling was false and misleading by reason of its failure to reveal facts with respect to consequences which may result from its use under the conditions of use prescribed on the label. There was present in each tablet of the preparation $\frac{1}{2}$ grain (0.03 Gm.) of desiccated thyroid, containing approximately 0.3 per cent organic iodine, which is about 50 per cent more organic iodine than is present in desiccated thyroid U. S. P., producing consequently greater physiologic effect than equivalent amounts of a U. S. P. product of desiccated thyroid. It was the failure of the label adequately to conform to the provisions of the act because of the presence of the desiccated thyroid in the preparation that formed the real basis of the government's libel. According to the labeling of the preparation, it is intended as a cure for obesity and is for use only by obese persons who are otherwise normal and healthy and whose obesity is caused by hypothyroidism with accompanying subnormal metabolism. The labeling further represented that hypothyroidism is the basic cause of obesity, which results from a lack of a substance which Marmola supplies, and recommended a dose, where indicated, of four tablets daily. This daily dosage recommended is equivalent to 2 grains (0.13 Gm.) of desiccated thyroid containing 0.3 per cent organic iodine, or to 3 grains (0.2 Gm.) of desiccated thyroid containing 0.2 per cent organic iodine in a U. S. P. product. The trial court found under the circumstances that the Federal Food, Drug and Cosmetic Act had been violated because Marmola tablets, when used in the dosage and with the frequency, and for the duration prescribed, recommended or suggested in their labeling are dangerous to health. The circular accompanying each bottle of Marmola recommended that the user take one Marmola tablet before each meal and one at bedtime over a period of sixty to ninety days—if needed that long. The circular advised the user to stop taking Marmola if he or she lost abnormal excess weight if later weight was redeemed and to resume the taking of Marmola tablets until conditions are corrected and to consult the user's physician if any unusual circumstances or conditions arise.

The essential question in this case, said the circuit court of appeals, is whether the evidence before the trial court is such as to justify us in saying as a matter of law that the trial court's finding that the Federal Food, Drug and Cosmetic Act had been violated because Marmola Tablets when used in the dosage and with the frequency and for the duration prescribed, recommended or suggested in their labeling are dangerous to health is erroneous. Obviously, said the court, the trial court's finding should not be set aside unless clearly against the weight of the evidence. The Raladam Company has sold this concoction for more than thirty years as a reducing aid for persons whose obesity is supposed to be caused by hypothyroidism and

who have an accompanying subnormal metabolism. "Hypothyroidism," resulting from underfunctioning of the thyroid gland, is accompanied by a subnormal metabolic rate and such symptoms as dryness of the skin, scarcity of hair and eyebrows, sluggishness of physical and mental reactions, decreased appetite, slower pulse rate and characteristic changes in the composition of the blood, and, in advanced stages, by a puffy and swollen appearance of the face and other parts of the body due, not to increased fatty tissue, but to mucoid fluid deposited beneath the skin. "Metabolism" denotes the sum total of all processes of the human body by which food is transformed into chemicals in turn absorbed into the blood stream and lymphatic system for the purpose of so nourishing the body that it can continue to function. In other words, it is the aggregate of all processes whereby food is digested, heat and energy created, the body built up or repaired and waste matter excreted. By examination of the rates at which normal persons give off heat, scientists have established the normal rate of metabolism from which, experience has revealed, most persons deviate by not more than 10 per cent. To enjoy good health, one's body must maintain a proper balance of essential chemicals; the thyroid gland is the primary agency in achievement of this end. Excess of the thyroid hormone in the blood stream results in hyperthyroidism and too little in hypothyroidism. The only ingredient of the condemned drug with which the proceeding was concerned is the desiccated thyroid included in the formula. This is derived from the glands of hogs and sheep and has the same effect on one's physical makeup as the hormones produced by a human gland. The potency of desiccated thyroid is roughly proportional to its iodine content. The product here contains approximately 0.3 per cent of organic iodine and thus possesses one and one-half times the potency of that made in accord with the standard of the U. S. Pharmacopeia.

At the trial, continued the court, qualified authorities and specialists in medicine, chemistry and nutrition supplied testimony, somewhat in conflict, relating to the cause and "cure" for obesity, hypothyroidism and hyperthyroidism and to metabolism, as well as proof of the effect of thyroxin on persons suffering from Graves' disease, heart disease, amenorrhea and psychoneuroses. The evidence disclosed that an overdosage of desiccated thyroid produces hyperthyroidism. Indeed, as to this there can be no question, since such medication supplies an excess of the hormone. The record also reveals that medical men are in agreement that one person's tolerance for the drug may be a great deal less than another's. The Raladam Company recognizes this too, since in the circular it warns "No food, drug or other substance which has any physiological effect may be taken internally or applied externally without the possibility of unpleasant or harmful results in some persons if they happen to be constituted so that they do not tolerate the food or other substance. . . . If any unpleasant effects are experienced stop taking Marmola until they disappear." Medical witnesses testified as to further effects of overdosage, such as increased metabolism of the patient, injuriously affecting the functioning of the endocrine glands, kidneys and liver; impairment of bodily functions because of the extra burden placed on human organs; symptoms which cannot be distinguished from those peculiar to hyperthyroidism, such as rapid heart, heart pains, nervous and emotional instability, nausea, menstrual disturbances and serious aggravations which result in persons who consider themselves normal and healthy but are actually subject to such latent diseases as heart disease, diabetes or tuberculosis, when they use desiccated thyroid. Indeed, their testimony is largely to the effect that a daily dosage of 2 grains a day is dangerous to health. Lay witnesses gave vivid reports of the effect of the tablets on their health. Weakness, heart palpitations, amenorrhea, emotional nervous states and domestic difficulties were described as aftereffects of the use of the tablets.

We think, continued the court, that the evidence adduced before the trial court was such as to justify only the conclusion reached by that court and we certainly are not justified in saying that the finding is erroneous as a matter of law. Admittedly, taking four tablets a day is not dangerous to the health of all users, since tolerance for the drug varies; but the

experience of various witnesses, all of whom took tablets according to the directions on the label, as well as the testimony of a number of medical experts, inevitably impels one to the finding that use of the tablets as prescribed is dangerous to the health of the public. The fact that some users may be able to tolerate greater quantities does not militate against the conclusion for the Federal Food, Drug and Cosmetic Act does not require that the drug be dangerous to the health of all who take it in the dosage and for the duration prescribed or recommended. It devolved on the trial court to determine only whether it was proved that the drug is dangerous to the public health at large if used as recommended by its vendors.

The trial court, said the appellate court, further found that the Marmola tablets were subject to condemnation in that they were misbranded because they were falsely represented to be a safe and appropriate remedy for obesity, when in fact they are not, because obesity is not caused by the lack of any substance which Marmola supplies, and in that the labeling did not reveal facts material with respect to possible consequences of use of the tablets under the conditions prescribed, since the instruction to discontinue use of the tablets on appearance of "unpleasant effects" does not prevent the occurrence of more serious symptoms as a result of the hyperthyroidic condition previously precipitated.

The Raladam Company, said the court, attempts to make much of the proposition that the legislative history of the Federal Food, Drug and Cosmetic Act discloses that Congress had no intent to deprive individuals of the right of self medication. This we think beyond the point, for the decision of the lower court deprives no one of this right. It merely determines that Marmola tablets are dangerous to the public health when used in the dosage and with the frequency prescribed by its manufacturers. What would be a nondeleterious prescription was not agreed on by the experts testifying at the trial and was not within the province of the court to decide.

Accordingly, the judgment of condemnation was affirmed—*United States v. 62 Packages, More or Less, of Marmola Prescription Tablets*, 142 F. (2d) 107 (1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Diseases of Children, Chicago

67:341-428 (May) 1944

Deficiency Anemia in Infants: Report of 2 Cases, with Associated Temporary Deficiency of Antianemic Factor in 1 and Allergic and Abnormal Digestion of Protein in the Other. M. H. Bass.—p. 341. Serum Phosphatase Activity and Clinical Rickets in Children in Jerusalem. R. Klammer.—p. 348.

*Cystic Fibrosis of Pancreas: Report of 18 Proved Cases. Maud L. Menten and T. O. Middleton.—p. 355.

Fatal Effects of Prolonged Complete Curarization. M. A. Perlstein and A. Weinglass.—p. 360.

*Studies on Control of Acute Infections of Respiratory Tract: III. Results of Sulfadiazine Therapy from May 3, 1942 to May 2, 1943. M. Siegel.—p. 365.

Serum Tocopherol: Its Relation to Failure of Vitamin E Therapy for Pseudohypertrophic Muscular Dystrophy. A. S. Minot and Helen E. Frank.—p. 371.

Ascorbic Acid, Riboflavin and Thiamine Content of Cow's Milk. A. D. Holmes, C. P. Jones and Anne W. Wertz.—p. 376.

Poliomyelitis: II. Results of Treatment During Acute Stages of Disease. J. A. Toomey and P. M. Kohn.—p. 393.

Cystic Fibrosis of Pancreas.—According to Menten and Middleton children suffering from cystic fibrosis of the pancreas show failure to gain weight, wasting, vomiting, diarrhea or constipation, protuberant abdomen, bulky fatty intestinal contents, cough and terminal bronchopneumonia. They report 18 cases in which diffuse definite dilatation of the pancreatic acini and associated pneumonia were observed at necropsy. A clinical diagnosis of cystic fibrosis of the pancreas was made in 1 child. The 18 cases were gleaned from 640 necropsies performed at the Children's Hospital in Pittsburgh from Jan. 1, 1936 to June 1, 1943 and represent 2.8 per cent of the total number. During the same period celiac disease was diagnosed in 15 cases. Cystic fibrosis of the pancreas was diagnosed in only 3 of the cases during life, largely because of lack of presenting symptoms. No definite causes for the pancreatic changes have been found. It is probable that pancreatic lesions precede the atresia and are the cause and not the result of these rare abnormalities. The theory of fetal inflammation fails because of the absence of inflammatory cells and the presence of normal islet tissue. Congenital syphilis may produce a pathologic picture in the pancreas approximating cystic fibrosis, but other characteristics of this disease are absent. Congenital malformations of the acini or alterations in the pancreatic secretions have not been demonstrated. The fact that there are pathologic changes in accessory pancreatic tissue in the jejunum which are identical with the changes in the main organ argues that intrinsic biochemical alterations in the acinar epithelium are probably a fundamental etiologic factor.

Sulfadiazine in Acute Infections of Respiratory Tract.—Siegel made his observations in an institution for feeble-minded patients among children highly susceptible to infections of the respiratory tract and to secondary bacterial complications. The children varied in age from 2 to 15 years, the average being 8.1 years. A group of about 130 girls lived in cottage Y and an approximately equal number of boys in cottage Iota. New admissions to each cottage replaced withdrawals at the rate of about 1 per week. The duration of residence varied considerably. The children were assigned to the control or to the sulfadiazine treated group in alternate order of admission. The groups were comparable with regard to age, weight, frequency of mongolism and past incidence of pneumonia and other acute infections of the respiratory tract. The children in the two groups were managed alike, except for the use of sulfadiazine in the treated group at the onset of clinical infections of the

respiratory tract. The period of observation lasted from May 1942 to May 1943. During these periods 250 acute infections of the respiratory tract were studied in 130 patients. The results obtained are similar to those noted during the first six months of the study, which were reported previously. The illnesses were milder in the drug treated groups than in the untreated groups, with the exceptions noted in outbreaks of infections presumably of virus origin and in sporadic infections. The beneficial effects were attributed to the bacteriostatic action of sulfadiazine. The differences observed between the untreated and the treated groups varied considerably. Although the severity of the illnesses in the control group fluctuated with the year to year variations in severity of infections prevalent at the time, the infections in the treated group appeared to be relatively mild. The drug seemed to exert a stabilizing effect on the course of acute infections of the respiratory tract. Such an effect might prove to be of value during severe outbreaks of influenza and other respiratory diseases in which drug susceptible bacteria may be primarily or secondarily implicated.

Depressor Effects of Cold on Static Receptors of Labyrinth. E. Spiegel.—p. 404.

Effect of Sodium Thiocyanate on Pressor Action of Renin-like Substance. J. W. Dalton and F. R. Nuzum.—p. 415.

Effect of Sodium and Potassium Chloride on Renal Clearance of Ascorbic Acid. E. E. Selkurt and C. R. Houck.—p. 423.

Mechanism of Sucrose Damage of Kidney Tubules. H. A. Wilmer.—p. 431.

Copper and Hemopoiesis in Experimental Hemorrhagic Anemia.—Maass and his collaborators report studies on young growing dogs which were kept on a raw milk diet supplemented with crystalline B vitamins and manganese and rendered anemic by bleeding. Blood analysis showed a characteristic picture of secondary anemia. The anemia showed no response to dietary supplementation of iron in the absence of copper. The daily administration of 3 mg. of copper brought about an immediate and rapid increase in hemoglobin, hematocrit and red cell counts to normal values. An iron deficiency in the presence of adequate (3 mg.) copper caused a nutritional anemia and a concomitant decrease in mean corpuscular volume. The administration of 10, 20 or 30 mg. of iron with 3 mg. of copper gave the characteristic remission in the anemic dogs.

Gelatin and Saline Solution as Plasma Substitutes.—Swingle and his associates found that the application of a Duncan-Blalock press to one hind leg of a deeply anesthetized dog for seven hours at 750 pounds pressure induced fatal shock in 25 of 26 untreated control animals. The average survival period following release of the press was eleven hours. The shock is characterized by intense hemoconcentration, progressive fall in arterial pressure and loss of plasma. There is an average decline in plasma volume of 48 per cent. The greatly swollen leg indicated that most if not all of the plasma volume decline could be accounted for by plasma loss into the injured area. A

single massive intravenous infusion of gelatin, representing 40 cc. per kilogram, given immediately after removal of the leg press, failed to prevent fatal shock in 10 of 11 dogs. The gelatin was apparently not retained in the circulation but rapidly passed through the injured capillaries of the limb. Six intermittent gelatin infusions of 6.6 cc. per kilogram each, administered over an eight hour interval from the time of removing the leg press, prevented shock in 19 of 26 animals. Intermittent infusions of 0.9 per cent saline solution, administered in equal dosage and over the same time interval as the gelatin, proved to be less effective. Eight of 23 dogs survived, whereas 15 died. Small intermittent infusions of pooled, heparinized dog plasma administered in the same dosage and over the same time interval proved no more effective in preventing shock than similar infusions of gelatin. The authors conclude that intermittent infusions of plasma or plasma substitutes, when given in small amounts over a period of hours, are more effective in preventing shock than is a single massive infusion.

Malaria and Chemotherapy in Neurosyphilis.—Dattner and his associates stressed in a previous report the importance of spinal fluid examinations as the most reliable criteria for determining the activity of a syphilitic process in the central nervous system. Symptoms and signs usually associated with dementia paralytica or tabes dorsalis may occasionally be due to other causes than syphilis. In the presence of positive specific tests for syphilis the best available guide to determining the activity of a syphilitic infection of the central nervous system is increase in the cells and protein of the spinal fluid. It has been the policy at Bellevue Hospital since Jan. 1, 1939 to treat all patients whose spinal fluid is actively syphilitic, regardless of the presence or absence of clinical signs and symptoms, with some form of fever in addition to chemotherapy, unless fever is definitely contraindicated by the general condition of the patient. Fever was induced with malaria in all the patients. The number of malarial paroxysms was limited to eight. This was followed immediately by chemotherapy. At first patients were given alternate courses of weekly injections of arsenical drugs followed by bismuth for a period of six months after malaria. Later the authors shortened the period of treatment by giving one injection of 0.06 Gm. of mapharsen daily for ten days following the last fever, while the patient was still in the hospital ward. No significant differences were noted in the two groups. The spinal fluid was examined six months after the completion of therapy. If this showed no more than 4 cells per cubic millimeter and definite reduction in protein content, no further antisyphilitic treatment was given. The patients were kept under observation, and spinal fluids were examined every six months. Patients whose spinal fluids still showed signs of activity six months after treatment were either returned to the hospital wards for retreatment or given some type of chemotherapy. Of the 419 patients who received 424 treatment courses 10 died, 62 are lost and 54 have been treated too recently for evaluation. The report of the results of therapy is limited to 293 patients, or 298 treatment courses. Of the patients who were followed from six to forty-eight months 85.9 per cent showed satisfactory results.

Triple Typhoid Vaccine in Treatment of Syphilis.—According to Lawrence, arsenical toxicity is diminished when fever is given with chemotherapy. The combination of fever and intensive chemotherapy requires less arsenic for the same

therapeutic efficiency than does chemotherapy unaccompanied by fever. Patients who have had arsenical exfoliative dermatitis can tolerate further arsenicals if these are given in combination with fever therapy. The technic employed consisted of a continuous infusion of typhoid vaccine in a saline suspension as described by Solomon and Somkin. The infusion was prepared by adding the selected amount of army triple typhoid vaccine to 1 liter of saline solution, which was then shaken thoroughly. The solution was administered intravenously by an Abbott drip infusion apparatus. When it was clear that fever produced by this technic was well tolerated even when combined with chemotherapy, 0.06 Gm. of mapharsen was given intravenously with every paroxysm of fever in all subsequent treatments. Twice a week, on days on which fever was not given, 0.13 Gm. of bismuth subsalicylate in oil was injected intramuscularly. Forty hours above 104 F. was considered to be the optimum amount of fever for a course. Approximately ten treatments of four hours each above 104 F. was the method by which this was obtained. To date 10 patients have been treated by the infusion of triple typhoid vaccine without serious complication. No manifestations appeared of tetany, cerebral edema, dehydration or cardiac failure. The two instances of vasomotor collapse responded readily to corrective measures. Antisyphilitic therapy with arsenicals can be given at the height of the fever; this is not possible in malaria therapy. The necessity of continuously administering oxygen, as recommended in the use of a fever cabinet, was eliminated. It was gratifying to be able to maintain a patient for eight hours between 104 and 106 F. during the day and see him up and about the ward that evening. Because of its simplicity this technic of inducing fever is especially suited to army facilities.

Radioactive Iodine in Thyroid Carcinoma.—Frantz and his associates reported in 1942 an instance of storage of radioactive iodine in a metastasis from a thyroid carcinoma. They now present a completed report of this case, observed until death. When the radioactive isotope of iodine became available, it afforded an easy method of checking iodine storage in metastases from thyroid carcinoma. The radioactive iodine produced by the cyclotron is mixed with inert iodine compounds such as potassium iodide and is usually administered by mouth. The patient, a Negro woman aged 39, first complained of swelling of the neck of seven years' duration in 1934. At this time a vascular tumor was removed from the isthmus of the thyroid. In 1941, seven years after operation and fourteen years after the tumor was first noticed, the patient sustained a pathologic fracture of the left humerus. A roentgenogram showed areas of bone destruction in the shaft of the humerus near the deltoid tubercle, and a small fracture line on the medial border. There was a soft, pulsating oval tumor about 8 cm. in diameter projecting 4 cm. above the scalp in the region of the left parietal bone. Further roentgenograms showed areas of bone destruc-

tion in the lower end of the right femur and in the left parietal bone. Roentgen irradiation was applied to the lesion of the humerus and later to the thigh and to the tumor of the parietal bone. Roentgen treatment of the latter two regions was interrupted for the administration of a tracer dose of radioactive iodine, which was given orally in water. The substance was taken up, as shown by the Geiger counter, in considerable quantity by the metastasis in the right femur and by the thyroid but not by the other bony metastases. It was suggested that a larger dose might afford selective therapeutic "internal irradiation," and 10 millicuries was given. The right femoral metastasis showed no change in radioactive iodine content during the first week, but when measured again at the end of three weeks it showed loss of 85 per cent of its radioactive iodine. A tracer dose given a few days later showed no further uptake by the metastasis, although there was new localization in the thyroid. This was interpreted at the time as evidence of the effectiveness of this "internal irradiation." The patient died. At necropsy the bulk of the metastatic tissue was undifferentiated. The metastasis which showed consistent uptake of iodine was the only one which grossly resembled thyroid tissue and which microscopically showed well differentiated tumor. The authors know of no evidence that external irradiation of thyroid carcinoma may change the microscopic character of the tumor. They believe that two types of tumor were present. There was no uptake of radioactive iodine in most of the lesions. Since some well differentiated tumors of the thyroid are capable of storing iodine, it is thought that in selected cases therapeutic internal irradiation of metastases may be achieved with large enough doses of radioactive iodine. Tracer doses of iodine may be valuable diagnostically. Failure of uptake does not mean that the tumor is not of thyroid origin.

Primary Hemangiomatous Tumors of Skeletal Muscle.—Shallow and his associates report 2 cases of primary hemangiomatous tumors of skeletal muscle. A woman aged 35 noted over a period of five years a slowly growing mass on the lateral aspect of her left thigh which pulsated, had a bruit and was unassociated with any symptoms except slight pain. Temporary ligation of the left common iliac artery was followed up by wide excision of a partially circumscribed hemangioendothelioma involving three contiguous muscles. Postoperative high voltage roentgenotherapy was given. Complete recovery ensued without loss of function. The second patient was a boy aged 10 years who noticed a lump on the inner aspect of his right arm following trauma. The lump increased in size and became painful. Physical examination revealed a soft, tender, walnut sized mass over which a bruit could be heard. A cavernous hemangioma involving the medial head of the triceps muscle was removed at operation. During the next two years a mass gradually appeared on the posterior aspect of the arm, accompanied by pain and limitation of extension of the forearm. Wide excision was followed by primary wound healing and complete restoration of function. The author presents an analytic review of 335 cases of primary hemangiomatous tumors of skeletal muscle. The disease occurs about equally in the two sexes and most frequently (85 per cent) during the first three decades of life. The prevailing view is that hemangiomas are congenital tumors originating from abnormal embryonic sequestrations of vascular tissue. Trauma and systemic infection, acting as secondary factors, may modify subsequent growth. The lesion arises in the vascular plexus of the muscle or in the perimysium between the muscle fibers and often resembles a muscle containing varicose veins. The tumor consists of vascular elements in a connective tissue stroma and is classified as cavernous, capillary, venous or arterial. Although pure types seldom exist, the cavernous variety is the most common. Growth is by a multicentric proliferation of endothelial cells forming vascular channels with practically no tendency to anastomose with the normal vessels in the invaded tissue. There are no proved cases of metastasis from a primary muscle hemangioma. The diagnosis was correctly made in only 19 per cent of the cases. The history usually reveals a clinical onset early in life, often following trauma to the part. The thigh is most commonly involved, especially the quadriceps femoris muscle.

The diagnosis may be confirmed by aspiration of blood from the tumor and by the presence of phleboliths on roentgenologic examination. Angiography may also be employed as an adjunct in diagnosis. The procedure of choice in treatment is early complete surgical excision well beyond the confines of the tumor. This was the treatment employed in 79 per cent of the cases, with improvement or cure in 90 per cent. In cases in which malignant degeneration is suspected, postoperative high voltage roentgenotherapy is advocated. There was no surgical mortality. Local recurrence or lack of improvement was reported in 6 per cent of the cases and postoperative deformity in 4 per cent.

Annular Pancreas Producing Obstruction.—A newborn infant with evidence of duodenal obstruction came recently under the care of Gross and Chisholm. Roentgenologic examination with the child in the recumbent position showed some dilatation of the stomach and a bubble of gas in the right upper quadrant of the abdomen, which was assumed to be air in a dilated first portion of the duodenum. No gas could be found in any other part of the abdomen. These findings were interpreted as representing a complete obstruction of the duodenum. The malformation was found at operation. The authors left the local abnormality undisturbed and performed a side to side duodenojejunostomy. The jejunum was brought upward and laid against the anterior wall of the dilated first portion of the duodenum so that an isoperistaltic type of anastomosis could be established. The baby was discharged from the hospital on the sixth postoperative day. There was no vomiting; she was taking her feedings well. Subsequent development of the child has been normal. The constriction of the duodenum is not always sufficient to cause clinical symptoms. If symptoms of duodenal obstruction appear they should be relieved by surgical correction. Operative alleviation of the obstruction has been practiced by (1) division of the pancreatic ring, (2) posterior gastroenterostomy or (3) duodenojejunostomy. The authors believe that the first procedure is the least desirable and that the last one is the operation of choice. The case described is the only one which has ever been treated by this method.

Cerebral Metabolism in Hypoxia. E. S. Gurdjian, W. E. Stone and J. E. Webster.—p. 472.

Torular Granuloma Simulating Cerebral Tumor.—Swanson and Smith state that, although meningitis is emphasized as a common lesion of torular infections, it is not generally recognized that torulosis of the brain may simulate an intracranial tumor. The authors describe 2 cases of this type. A woman aged 49 was admitted to the hospital in the terminal stage of a progressive disease suggestive of an expanding intracranial lesion. She died before operation could be carried out. Necropsy showed three distinct, large, isolated tumor masses in the brain which grossly suggested metastatic colloid carcinoma. Microscopic studies revealed the true nature of the disease process. The second patient, a white man aged 36, had a history of proved torular infection of the lung. He presented the clinical picture of increased intracranial pressure, with localizing signs pointing to the posterior fossa. The presence of an infection of the central nervous system similar to that in the

preceding case was considered, but repeated studies of the spinal fluid showed that the cell count and the sugar content were normal and cultures negative for the organism. This indicates that changes in the spinal fluid may not appear for weeks after the onset of symptoms. In 2 typical instances of meningitis recently encountered the organisms were grown with ease from the spinal fluid as well as from the blood, urine and sputum. Roentgenographic examination of the chest showed no demonstrable lesions in either of these cases or in case 1 of this report. Roentgenographic examination of the chest is advisable in all cases in which cerebral tumor is suspected, and it may occasionally give a clue to torular infection. The cerebral lesion of torulosis may resemble a glial tumor; only section of the "tumor" reveals the characteristic appearance of a multiloculated cyst filled with gelatinous material. This "tumor" is unlike true cystic tumors in that the cavities do not empty themselves when opened. This is the most striking feature of the torular granuloma. The tendency to isolation and sharp demarcation from the adjacent cortex, together with the absence of reaction in the surrounding tissue, is another striking feature of torular granuloma, but there exists the danger that the cyst will be opened unawares and meningitis initiated. The authors believe that this was done in case 2.

Treatment of Psychosis Due to Estrogen Deficiency.—Danziger presents an analysis of 164 cases of involuntional melancholia in which estrogen therapy was employed. Among these 164 women there were probably many in whom the psychosis developed either before or many years after the onset of the menopause. Such patients could not reasonably be supposed to be suffering from a psychosis due to estrogen deficiency and could not reasonably be expected to recover with estrogen therapy. The author classifies the patients into two groups, depending on whether estrogen deficiency was or was not involved. With patients whose psychosis was due to estrogen deficiency large doses of estrogen gave better results than small doses. Where psychosis was not clearly attributed to endocrine disturbances, the results did not vary with the dose. With patients in the first group, large doses gave results of the order of magnitude to be expected from specific therapy. With patients in the second group, results to be expected from specific therapy were never attained regardless of the dose. Although the two groups were not homogeneous as to the cause of their psychosis, they were both grouped according to the Statistical Manual of the National Association for Mental Hygiene under "involuntional melancholia." The author suggests that the term "involuntional melancholia" be replaced by "psychosis due to estrogen deficiency." In the absence of accurate evidence of disturbances in the climacteric immediately preceding the psychosis, the chances of recovery with estrogen therapy are not better than even, although the clinical picture may be that of involuntional melancholia. If such patients are given estrogen therapy, their chances of prompt improvement are much better than if they do not receive special treatment.

Tuberculosis in Routine Examinations for Induction.—Marcy points out that the requirement of a routine chest roentgenogram by military authorities has resulted in the biggest tuberculosis case finding program ever attempted. The government has set a high standard of disqualifying lesions in its determined effort to keep tuberculosis at a minimum in the armed forces. The disqualified men are reported to the state health departments and then referred to their family physicians or to tuberculosis clinics for further observation and treatment. The rejectees fall into three groups. The first group includes those with minimal healed disease, probably not of clinical significance but of a degree not acceptable to the Army. In most instances they can return to their regular occupations. Such a diagnosis of tuberculosis without a detailed explanation of its significance is unfair to the men examined. In order to dispel any undue fear, they must be given an explanation of their condition. The second group is made up of men with a disease of undetermined stability. A history must be taken in order to discover whether the patient is being exposed to tuberculosis. Also previous unexplained hemoptysis or recurring pleurisy is of possible significance. Cough, expectoration, fatigue, lack of endurance and gradual loss in weight must be taken into account. Localized rales in the upper lung areas are important. Age is extremely important. Apparently healed primary tuberculosis is less significant in a man beyond 40 than it is in a youth of 18 years. Nutrition, social status, environment, habits of living and the nature of his employment together with the amount of rest must be considered. Some may need a preliminary period of hospital study, but most of them can continue at home under the guidance of their own physician. In many cases it is merely a question of establishing their work tolerance. The third group is composed of those with active tuberculosis. The majority are in an infectious stage and should have hospital care. Unless the medical profession takes an intelligent interest in the men disqualified by the military authorities because of tuberculosis, this effective case finding procedure will lose much of its value as applied to the prevention and control of tuberculosis in the civilian population.

Effect of Liquid Petrolatum, Lanolin-like Substances and Killed Tubercle Bacilli on Immunization Procedures.—Freund and Bonanto found that when rabbits receive injections of diphtheric toxoid incorporated in a lanolin-like substance, antitoxin formation is enhanced and prolonged as compared with antitoxin production after the injection of plain toxoid. The lanolin-like substance sustains antitoxin formation more effectively than alum. When an aqueous suspension of

killed typhoid bacilli is mixed with a lanolin-like substance and liquid petrolatum the bacteria are found in microscopic water droplets surrounded by oil. Preparations of this kind are stable. Liquid petrolatum enhances and sustains antibody formation against typhoid bacilli for a remarkably long time. Killed tubercle bacilli have an additional synergistic effect. Peanut oil has scant or no effect when compared with liquid petrolatum.

Prophylactic Use of Sulfanilamide in Inactive Rheumatic Fever.—Dodge and her associates administered sulfanilamide at Bellevue Hospital to 88 patients ranging in age from 6 to 18 years during the fall, winter and spring months for a total of 181 patient-seasons. Seven children received the drug for four seasons, 19 for three seasons, 48 for two seasons and 30 for one season. The children were given from 1 to 2 Gm. of sulfanilamide daily. One hundred and one rheumatic children were observed as controls for 138 patient-seasons. Toxic drug reactions were minimal. The drug was not discontinued permanently in any case for such a reaction. During the period of the study there were in the control group 54 hemolytic streptococcus infections, an incidence of 39 per cent. There were 19 definite major rheumatic relapses (with two deaths) and 7 mild or possible relapses. In 3 children the rheumatic process remained active throughout the period of observation, and there was one death from subacute bacterial endocarditis. In contrast to this, only 5 hemolytic streptococcus infections occurred in the group of children receiving sulfanilamide prophylaxis, an incidence of 2.7 per cent. Two children, or 1.1 per cent of the patient-seasons of prophylaxis, developed definite rheumatic relapses while taking the drug regularly. Two other children with severely damaged hearts died of congestive failure without evidence of streptococcal infection or active rheumatic disease. Two children with recently active rheumatic fever

showed signs of increasing rheumatic activity within two weeks of starting the drug. The authors concluded that the effectiveness of sulfonamide prophylaxis in quiescent rheumatic fever is established and that it should be applied more widely among groups of highly susceptible individuals.

Single Dose of Sulfadiazine in Pneumonia.—Alternate children admitted with pneumonia were treated with single doses of sulfadiazine, while the others were treated with a regular course of sulfadiazine. Twenty-five children ranging in age between 8 months and 10 years were treated with a single dose. With one exception, sulfadiazine was given by mouth in a single dose of not less than 0.15 Gm. per kilogram of body weight. Smaller children weighing up to 20 Kg. received relatively higher doses, from 0.2 to 0.3 Gm. per kilogram of body weight. The maximal dose was 5.0 Gm. of sulfadiazine. Fluid was forced during the days after the administration of the drug, but no sodium bicarbonate was given. The control group of 23 children were treated with 0.2 Gm. of sulfadiazine per kilogram of body weight for the first days, followed by 0.1 Gm. per kilogram of body weight daily in divided doses and continued until the temperature was normal for two days. The authors found that uncomplicated pneumococcal pneumonia in children seems to respond as promptly to a single dose of sulfadiazine as to continued doses of this drug. The temperature dropped to normal in from four to ninety-six hours, or an average of 38.4 hours, following the single dose, and in from six to one hundred hours, or an average of 40.1 hours, when a full course of sulfadiazine was given. No toxic manifestations appeared following the single dose treatment. It is simpler and less expensive, and it may decrease the risk of toxic manifestations and sensitization to the drug. Three patients with pneumonia complicated by otitis media did not respond to the single dose treatment. The single dose treatment is not recommended for hospitalized, serious or complicated cases of pneumonia, but as an expedient for ambulatory cases or occasions when proper care is lacking.

Cancer of Prostate. A. R. Sugg.—p. 206.
Congenital Defects of Sternum, with Report of a Case. J. F. Burton.—p. 210.

Clinical Observations in Use of Penicillin.—In accordance with a suggestion of the Surgeon General's Office, a board of medical officers consisting of men from the medical, surgical and orthopedic services and the hospital bacteriologist was appointed for the purpose of selecting patients for treatment with penicillin and for evaluating its effect. Denny and his collaborators found it most practicable to treat the majority of patients in a special penicillin ward. The drug is kept in the ward in refrigerators, the temperatures of which are maintained at approximately 4 C. Fresh solutions are made up each day with pyrogen free isotonic solution of sodium chloride. The intramuscular administration is the method of choice in most cases because of its simplicity. A technician can be trained to give the treatments, less supervision is required, and the majority of infections respond satisfactorily. For local application a solution containing 100 to 250 units of penicillin per cubic centimeter is prepared with isotonic solution of sodium chloride as a solvent. When practicable, wet dressings are applied to the wound and are overlayed with an impervious material. The authors analyze 276 cases treated by them. Penicillin appears to be highly effective in the treatment of sulfonamide resistant gonorrhea, as evidenced by the fact that 98.7 per cent of 243 patients were cured with 50,000 and/or 100,000 units. There was a satisfactory response to penicillin in all patients suffering from infections caused by streptococci of the beta and alpha types, and pneumonia caused by the pneumococcus. Infections due to *Staphylococcus aureus* responded satisfactorily in those whose lesions were superficial, in whom adequate drainage was instituted or in whom the disease was relatively acute, but in those in whom drainage was incomplete or in whom a foreign body or sequestrum existed the results have been unsatisfactory. No conclusion can be drawn from the authors' observations in the treatment of acute rheumatic fever in view of the fact that relatively small doses were used in 4 patients. Clinical and bacteriologic observations indicate that penicillin is highly effective in the treatment of Vincent's infection.

*Studies in Trichinosis: XVI. Epidemiologic Considerations Based on Examination for Trichinae of 5,313 Diaphragms from 189 Hospitals in 37 States and District of Columbia. W. H. Wright, L. Jacobs and A. C. Walton.—p. 669.

Epidemiologic Aspects of Trichinosis.—Wright and his associates reported in a previous communication the findings of trichinae in the examination of diaphragm material from 5,313 necropsies in various parts of the United States. Of these, 855, or 16.1 per cent, were positive for this parasite. They find no correlation between trichina infection and sex, civil or military status, past military service, occupation, mental hospitalization, urban or rural residence, or social-economic status. The 5,313 cases included 769 persons of foreign citizenship or whose names indicated foreign extraction, of whom 181, or 23.5 per cent, were infected. Persons in the German and Italian groups totaled 380, of whom 109, or 28.7 per cent, were infected. A comparison of these figures with an incidence of 15.6 per cent in 4,219 American Negroes and white persons of English-Scotch-Irish descent would seem to indicate that persons of foreign extraction are more frequently exposed to trichinosis.

This applies only to persons in the German and Italian troops, since the infection rate in other foreigners was not significantly different than that for the group as a whole. Represented were 235 Jews, of whom only 5, or 2.1 per cent, were infected. Of the 855 positive cases 245, or 28.7 per cent, exhibited infections with live larvae, 142, or 16.6 per cent, infections with mixed live and dead larvae and 468, or 54.7 per cent, infections with dead larvae. There is evidence that death of the larvae may occur within a few years after infection. Within the continental limits of the United States exposure to trichinosis is nearly uniform in degree regardless of geographic or environmental factors. Control measures therefore must be enacted on a nationwide basis.

*Congenital Absence of Lung Diagnosed Before Death. E. R. Dewees and J. C. Howard Jr.—p. 389.

Congenital Absence of Lung.—Agenesis of the lung is a definite clinical entity. Its early recognition will give the patient a much better chance for life. Diagnosis may be made on the basis of x-ray examination, injection of iodized oil and bronchoscopy. Schneider has differentiated three main types of pulmonary agenesis. The first type is a true aplasia with no trace of lung, bronchus or vascular supply on the affected side. The second type is characterized by a small outpouching from the trachea, with rudimentary bronchus. In the third type the bronchus is fully formed but ends in a fleshy mass of areolar tissue of varying amount. The different types of pulmonary agenesis may be explained on an embryologic basis. The left lung seems to be absent more frequently than the right lung. The incidence of the condition is about the same in the two sexes. The authors report a case of pulmonary agenesis which represents the second one of this type of congenital defect seen at their hospital during the last six years. The patient was a boy aged 6 months. The admission diagnosis was atelectasis of the right upper lobe. Roentgenographic and bronchographic examination revealed that no air was entering the right lung, but the findings were considered not inconsistent with a true agenesis of the right lung. The child's condition became much worse and death occurred. Necropsy revealed no lung at all on the right side.

Serum Colloidal Gold Reaction as Liver Function Test.
—MacLagan found that the serum colloidal gold reaction is greatly influenced by the reaction and the ionic strength of the medium. The technic has therefore been modified by the introduction of a buffer solution, which permits the test to be performed in a single tube in a reproducible manner without preliminary standardization of the gold sol. The conditions chosen give a final serum dilution of 1 in 60, a pH of 7.8 and an ionic strength of 0.01. The results obtained in 200 jaundiced and 200 nonjaundiced patients suggests that the test is a valuable indicator of liver damage. The almost uniformly negative results in obstructive jaundice give it a particular value in distinguishing this condition from infective hepatitis or hepatic cirrhosis. The results in arsenical jaundice (40 per cent positive) were strikingly different from those in infective hepatitis (95 per cent positive), suggesting some essential pathologic difference in the two groups.

Pathology of Human Immersion Foot.—Blackwood reports observations on 14 specimens of immersion foot studied at the Department of Pathology of the University of Edinburgh. The specimens varied in type from a digital nerve to a whole foot and leg, and they have varied also in the interval which has elapsed between the period of exposure and the removal of the specimen. All the material has come from severe cases with the result that gangrene and bacterial infection have often been present. The large arteries showed no severe narrowing. Slight intimal and medial fibrosis was sometimes present, also edema. The smaller arteries showed narrowing only immediately proximal to chronic infection. No significant changes were seen in the capillaries, but there were pericapillary foci of chronic inflammatory cells in the cases complicated at some time by infection and/or gangrene. Fibrous narrowing of small veins, with evidence of old hemorrhage into and around their walls, was seen either near gangrenous extremities, in chronically infected leg stumps or near an old amputation. The large veins showed significant narrowing due to patchy recanalized thrombus only when the leg stumps were chronically infected. Stasis of blood on the venous side, with diapedesis, thrombosis and intimal fibrosis, did occur, but such changes

were restricted to areas close to gangrenous or chronically inflamed extremities. Involvement of muscle fibers increased peripherally. From four months onward the muscle picture was one of variation in fiber caliber, with relatively little fibrosis. These changes were indistinguishable from those due to denervation and were associated with degeneration of muscle nerves. In addition there were occasional small areas of replacement of peripheral muscle fibers by fibrous tissue. At twelve months there was evidence of reinnervation of proximally situated muscles in the lower limbs. At twenty-six months after exposure, restoration to normal had spread farther down the limb, but changes indistinguishable from prolonged denervation were still present. In all patients surviving exposure, some degree of nerve degeneration was present. In uninfected patients when bone was available for study there was new bone formation subperiosteally and around the haversian canals. This was evidence of repair of the initial osteoporosis, which is a clinical feature of early survivors. The microscopic studies on patients with immersion foot demonstrate that damage is done to all tissues of the extremity.

Fat Embolism in War Surgery.—Wilson and Salisbury think that a definition of fat embolism as a state in which globules of fat are present in the circulation of sufficient size to cause blockage of the intimate vascularities of various organs may be accepted in principle, though there is evidence that local action of the fat particles on the capillary walls may be a feature of the condition. Their study is based on 1,000 consecutive battle casualties admitted to the surgical wards of a military hospital. No attempt was made at selection; the only proviso made was that for patients who recovered the injury should have been serious enough to warrant their stay in hospital for at least a week. These patients suffered from all types of war injury, but 119 had fractures of the long bones only. There were 8 patients with clinical fat embolism among the 1,000 and 6 of the 8 died. The pathogenesis of this condition and the actual mechanism involved are not clear. There is no definite laboratory examination which can always be relied on for early diagnosis. Sputum examination is of doubtful value. Fat in the urine is diagnostic, but it appears rather late in the condition. Darkground illumination of the blood would appear to be the most helpful examination. The blood picture is important. The treatment of fat embolism is empirical. The authors suggest venesection if the blood pressure allows it, followed by intravenous administration either of whole blood or of dextrose in saline solution. Working on the fact that insulin may aid the liver to remove fat from the blood, the authors have used this and consider it helpful, although the results are by no means dramatic. Care must be taken not to increase the pulmonary edema. For the dyspnea and cyanosis the administration of oxygen is extremely helpful. Sedatives may be necessary in the irritative stage of cerebral embolism. When pneumonia develops, treatment is along the usual lines.

Sex Ratio of Pneumonia Mortality.—According to Martin an excess of male over female mortality has been a feature of the respiratory diseases, particularly of pneumonia. He analyzes the average male mortality expressed as a percentage of the average female mortality from pneumonia for the fifteen

years from 1924 to 1938 for the areas of London, the county boroughs, urban and rural districts and for four age groups. A table shows that urbanization had little effect on the mortality sex ratio at the younger ages and only to a slight extent in the oldest age group, but at ages from 15 to 65 years there was, excluding London, a distinct progression with urbanization. In each age group the males experienced a higher mortality than the females, and the males were at a greater disadvantage during infancy than in childhood or old age, but the striking difference between the sexes occurred at ages of 15 to 65, when the males had a mortality twice as large as the females. The large mortality sex ratio found at ages 15 to 65 suggests that the differences between the mortality of the sexes may be caused by occupations with a high pneumonia risk. There is little evidence of an occupational risk for males; however, some occupations, such as furnace tending, involve a direct risk of pneumonia. The liability of these men to respiratory diseases was attributed by Vernon to the abrupt changes in the temperature to which the men were exposed by the conditions under which they worked, i. e. hot, heavy and exhausting spells of work alternated with periods of rest. Other occupations involve a more indirect risk; these include innkeepers, hotelkeepers, bartenders and makers of alcoholic drinks. The prognosis of pneumonia is affected by previous indulgence in alcohol, and the aforementioned occupations have a higher proportion of heavy drinkers than does the general population, and these occupations have a high mortality from pneumonia. A greater susceptibility among males than among females to infection or a greater power of recuperation possessed by females may be a possible explanation of the general excessive male mortality. During the working years of life a considerable part of the large male excess must be attributed to an indirect occupational risk, the general conditions of life that an occupation involves, rather than to the type of occupation.

Epidemiology of Q Fever.—According to Derrick investigations in Brisbane revealed that Q fever is a rickettsiosis and that it occurred also among farm workers and others. It was named Q fever and the causative organism *Rickettsia burneti*. In seven years 176 cases of Q fever have been diagnosed in Queensland. Nearly all the 129 patients who lived in Brisbane were associated with meat works. Most of the 47 country patients worked on dairy farms. Investigation of native animals, cattle and ticks has indicated in outline the natural history of Q fever. Several steps in this outline need confirmation, and much detail remains to be filled in. First there is a basic cycle of infection with the bandicoot and probably other bush animals as reservoir, and *Haemaphysalis humerosa* and probably *Ixodes holocyclus* as vector. A bush worker may interrupt this cycle and get Q fever from the attack of *Ixodes holocyclus*. Cattle become infected probably through *Ixodes holocyclus* and perhaps through other ticks. It is possible that there is a secondary cycle: cattle—*Haemaphysalis bispinosa*—cattle. Ticks on the cattle (*Boophilus annulatus microplus* or *Haemaphysalis bispinosa*) are probably the source of human infection. It is suggested that inhalation of tick feces is the likely mode of entry of *Rickettsia burneti*.

Corneal Vascularity as Sign of Ariboflavinosis.—Of 536 Europeans, according to Scott, 37 per cent had corneal vascularity. Of 1,700 Africans, 5 per cent presented corneal vascularity. Judged by perleche, cheilosis and glossitis, the Africans had double the European numbers of ariboflavinosis. Corneal vascularity therefore cannot be taken as a guide to avitaminosis in the African. Of 136 Europeans who were examined by slit lamp, 70 took a course of riboflavin while

50 acted as controls. This therapeutic test was negative. The degree of vascularity fluctuates with or without riboflavin. Corneal vascularity cannot be accepted as a guide to avitaminosis in Europeans. All the Africans examined had a rim of pigment at the corneoscleral junction. It is possible that this rim of protective pigment explains the striking difference in African and European corneal vascularity.

March Fracture.—Salmon points out that diagnosis of march fracture may be missed because of absence of a history of direct trauma and the comparatively few physical signs. The fracture is most commonly seen in the third or fourth metatarsal bones. Always transverse, it occurs across the neck or distal end of the shaft and typically without displacement. The x-ray appearance is a "fine hairlike crack" and in consequence is easily missed. There is usually no history of direct trauma, more often a gradual onset of pain in the metatarsal region. Examination of the patient often reveals little apart from slight edema over the dorsum of the foot and tenderness over the metatarsal involved. The earliest x-ray sign is a slight raising or thickening of the periosteum around the neck or shaft. This is accompanied by all ill defined osteoporosis of the cortex. A fine transverse crack may be detected. The periosteal elevation becomes fusiform with an increasing density, forming the pre-callus stage. Callus formation then occurs, finally to be absorbed leaving a thickened cortex. If the patient is first examined during the periosteal reaction a mistaken diagnosis may result, the most important of which is a sarcoma, but in the absence of cortical disturbance subperiosteal spiculation and further x-ray investigation should exclude this. March fracture must also be differentiated from Köhler's disease and from syphilitic periostitis. The author saw 5 cases of march fracture at a naval hospital, and of these 2 are described. The great importance of the x-ray investigation of patients complaining of slight pain and swelling over the dorsum of the foot is stressed. Further films should be taken during the following fortnight in the absence of positive findings in the first. Treatment is that of any other fracture, namely immobilization and rest.

Epidemic of Hepatitis.—McArthur reviews 46 cases of hepatitis which occurred among the personnel of a hospital ship numbering 244. There was a hospital staff of 110 and a ship's staff of 134. There were 45 cases of epidemic hepatitis among the hospital staff and only 1 among the ship's staff. All patients had received yellow fever vaccine on the same day, and jaundice appeared thirteen to twenty-three weeks later. There was a remarkable uniformity in the mode of onset. The symptoms were those usually associated with so-called catarrhal jaundice. There were no fatal cases, but debility was severe. Laboratory investigations in the more severe cases revealed a secondary anemia and hyaline and granular casts in the urine. A vaccine contaminated by the virus of epidemic hepatitis seems the most probable source of the epidemic. Certain of the cases may have been the result of contact infection, as it is otherwise difficult to explain the selective way in which the hospital staff was affected.

Cardiac Output and Forearm Flow in Posthemorrhagic Fainting.—Barcroft and his associates think that vasovagal fainting reactions with acute fall of blood pressure and slow pulse demand detailed study because they constitute one manifestation of hemorrhagic or oligemic shock. They become increasingly frequent as hemorrhage increases in magnitude. Fainting occurs in 3.8 per cent of donors bled 440 cc., and the incidence rises to 8.5 per cent when the bleeding is increased to 540 cc. Studies of the effects of larger venesections on normal male volunteers show that of those bled 800 to 1,000 cc. 11 out of 28 fainted, and of those bled 1,000 to 1,200 cc. 15 out of 29 fainted. Some authors have ascribed fainting to lack of blood supply to the brain, others to vasodilatation in the peripheral vascular system and to bradycardia, a combination to which the term vasovagal syndrome was applied. The authors report studies on healthy young male volunteers. Cardiac output by a direct Fick method and mean right auricular pressure were measured by cardiac catheterization. Forearm blood flow was measured with the Levis and Grant plethysmograph, the arm being immersed in a water bath at 35 C. When cardiac output and arterial pressure are known, an estimate of the resistance to flow imposed by the peripheral arterioles may be made. During fainting after hemorrhage cardiac output and right auricular pressure are often substantially unchanged. The acute fall in blood pressure cannot be explained by bradycardia and decreased cardiac output; it is due to peripheral vasodilatation. Forearm blood flow is approximately doubled; since the blood pressure is about halved, this indicates pronounced vasodilatation. The vasodilatation cannot be in the skin, which is pale; it is in the arterioles of the underlying muscle. If vasodilatation of the same order occurred throughout the body musculature there would be a considerable drop in the blood pressure, possibly great enough to explain the fall in fainting. The vasodilatation is mediated by vasomotor nerves.

Vitamin K as Prophylactic in 13,000 Infants.—According to Lehmann, synthetic analogues of vitamin K appeared on the Scandinavian market in 1940 and prophylactic treatment of newborn infants was then started. He investigated the physiologic hypoprothrombinemia in 90 newborn infants by daily determinations during the first week after birth. For this purpose he used a micro modification of Quick's method. Forty of the 90 infants in which determinations were made belonged to the summer series, that is, they were born during July and August. The other 50 infants were spring births (March and April). It was found that during spring low prothrombin values were more common than in summer. The minimal but optimal dose of a vitamin K analogue for prophylactic treatment of newborn infants after birth was found to be 0.5 to 1 mg. and was as effective when given by mouth as by injection. A comparison of deaths from bleeding in 13,250 full term infants receiving vitamin K analogue with 17,740 untreated cases showed that 1.6 per thousand could be saved by the treatment and that general prophylaxis can be recommended, since the cost is low. Hemorrhagic disease of the newborn was found to include all forms of bleeding, and especially intracranial bleeding.

Sulfonamide Hemolysis Resembling Blackwater Fever.—Foy and his associates show that the intravascular hemolyses in blackwater fever, incompatible transfusions, hemolytic jaundice and hemolysis from various drugs resemble one another. They report a case in which benzyl sulfanilamide had been given. Complete quantitative pigment estimations in blood and urine were made and correlated so that a comparison between the pigment metabolism in this condition, blackwater fever, and the other intravascular hemolyses was possible, bringing out the resemblances and differences between them. Intracorporeal methemoglobin occurs after sulfonamides, plasmochin and acetanilid but does not occur in blackwater fever. Oxyhemoglobin, methemalbumin and hemobilirubin are common to all the intravascular hemolyses. It appears that p-aminophenol or one of its derivatives is responsible for the methemoglobinemia after aniline and acetanilid; it seems uncertain whether or not similar metabolites are responsible in the case of sulfonamides and plasmochin. In the case described there existed an acute massive intravascular hemolysis accompanied by the presence of plasma oxyhemoglobin, methemalbumin and hemobilirubin, as well as intracorporeal methemoglobin and a profound fall in the red cell count. Urinary methemoglobin may be present in the intravascular hemolyses, but its presence in the urine is not related to plasma methemalbumin or intracorporeal methemoglobin; nor is its formation entirely dependent on urinary pH or ionic concentration. Both oxyhemoglobin and methemoglobin were found in the urine. There was an almost complete anuria that was not associated with blockage of the renal tubules with precipitated products of hemoglobin. There were, however, changes in both the tubules and the glomeruli, such as are characteristic in blackwater fever and incompatible transfusions. It is suggested that the anuria and azotemia are secondary to more fundamental changes that occur in the blood stream and which lead to upsets in glomerular filtration, tubular reabsorption, anuria and azotemia, and that blockage is a secondary phenomenon. In the present case there was a great difference in the microscopic appearance of the kidney tubules and glomeruli in the paraffin and frozen material. It is felt that the distortion brought about by the dehydration consequent on the paraffin method makes this technic unsatisfactory for correctly assessing the changes that take place in these delicate structures in the anuric condition. The great increase in the osmotic resistance of the red cells to saline solution and to lysolecithin was not related to changes in the cell volumes, thicknesses, diameters or ratios, and the Price-Jones curve was within normal range. The authors feel that changes in the environment of the cells, perhaps in the nature of circulating hemolysins, are more fundamental than physical changes in red cell structure.

Infantile Rickets.—Wieland's experience in the pediatric clinic in Basel suggests that craniotabes in the form of supraoccipital softening not only is pathognomonic of rickets but also represents the primary positive clinical sign of rickets. Isolated localizations of rickets in the skeleton may continue for a long time and may disappear temporarily or permanently since rickets is a chronic, remittent disorder of metabolism. That is why supraoccipital softening of the cranium may be observed in healthy infants. This symptom may be overlooked

for the same reason and its nosologic importance may be misunderstood. For many years incipient craniotabes had been mistaken for congenital defect of the cranium culminating in a soft cranium. All congenital disturbances of ossification of the cranium prior to and after birth subside spontaneously and become normal within the first four to six weeks after birth. Any recent supraoccipital softening or any increase in congenital supraoccipital softening in infants regardless of the interval between its occurrence and birth is rickety in character and requires specific therapy. Recovery will take place on administration of vitamin D (irradiated ergosterol or Vi-De) in any instance of uncomplicated rickets. Massive doses of vitamin D for a short time are not superior to small doses for a longer period but may be preferred in rapidly advancing cases, in those complicated by pneumonia and in cases of premature birth.

Ineffectiveness of Sulfonamide Therapy for Severely Infected Wounds.—Paschoud states that local sulfonamide therapy by application of dusting powder, crystals or solution in severely infected or contaminated wounds failed since diffuse phlegmons, erysipelas and gas gangrene present a continuous threat. Three factors are responsible for this failure: 1. Any drying effect with tendency of diminishing the secretion of the infected wound, instead of increasing its lymphorrhea must be deleterious. 2. The determination of the p_{H_2} at intervals of two hours in 11 cases revealed the ineffectiveness of the local application of sulfonamide dusting powders in the control of the acidosis which develops in the deep recesses of the purulent layer of the wound. 3. It is Paschoud's experience that the normal course of an infected wound may be favorably influenced by a surface temperature up to 45 degrees (by contact with the potentiometer). Potentiometric determinations in those 11 cases demonstrated that the local application of sulfonamides does not prevent a progressive local drop in temperature.

Problems of Military Insurance. E. Bachmann, M. Kartagener and W. Löffler.—p. 789.

Primary Group Infection with Tuberculosis.—Löffler and Zwiugli report two endemics of primary group infections with tuberculosis. The person whose primary infection indicates a source of infection is referred to as the indicator. The person who transmits the infection is a donor and all the other members of the same group with tuberculosis are receptors, each of whom may have likewise served as an indicator. One of the groups consisted of 13 adults in a military unit. The donor was a man aged 24 with pulmonary cavernous tuberculosis. Primary tuberculosis developed within two years in these cases from contact with the donor. The receptors probably acted as donors for some of the cases. Open tuberculosis was demonstrated on examination of some of the receptors, and chain infection was caused by the donor and transmitted by some of the receptors. A primary complex was revealed in 10 of the 13 cases. Three of them presented the picture of phthisis with primary focus. Associated pleuritis was demonstrated in 10. The pleuritis in 9 resulted from contact at the same time as the primary complex or within a short time after its development. Fatal hematogenous infection secondary to

the primary complex occurred in only 1. The second group consisted of 9 persons, 3 adults and 6 children between the ages of 4 and 14 years living in the same household. The severe course of primary tuberculosis in 6 of these cases within a closed community suggested that the donor was to be found within the household. The examination of the members of the household demonstrated as donor a man aged 48 with tuberculosis of both upper lobes, with a large subclavicular cavity on the right side and aspiration foci in both inferior lobes. The sputum was positive for bacilli on repeated examinations. The infectivity of tuberculosis is emphasized and immunization experiments with BCG vaccine are suggested. The majority of the cases presented primary infections which were demonstrated on examination in the postprimary stage. Exogenous infection, therefore, should be considered in each case. The source should be sought not only after the demonstration of the last case but immediately after that of the first case in order to prevent further spread of the disease.

Coronary Sclerosis in Youths.—Arteriosclerosis of the type of isolated malignant stenotic sclerosis occurs in young persons. The specific inflammatory character of coronary stenosis resembles that of thromboangiitis obliterans (von Winiwarter-Buerger's disease). There is a consensus that the latter represents an inflammatory process. The resemblances of the two diseases are demonstrable by microscopic studies and by the clinical and anatomic sequences of coronary insufficiency, angina pectoris and myocardial infarcts, on the one hand and intermittent claudication, circulatory and trophic disturbances of the extremities, necrosis and gangrene on the other. Both diseases occur almost exclusively in men. There is also conformity with regard to age. Coronary stenosis represents Buerger's disease of the coronary arteries. Secondary arteriosclerosis occurs at a later stage of both conditions. This condition develops from the scar that was left in the wall of the vessel by the primary inflammation. Cholesterol is not the etiologic factor. Factors causing mild inflammation with little destruction of tissue play a part in the causation of Buerger's disease. The tendency toward recovery is predominant. The patient suffers chiefly from cicatrization. The concept of focal infection of mild virulence is suggested.

*Transfusion of Suspensions of Blood Globules. A. M. Romero Alvarez.—p. 805.

Pregnancy and Atelectasis. J. Melfi and A. Molina.—p. 812.

Transfusion of Suspension of Blood Corpuscles.—Romero Alvarez prepares corpuscle suspensions as follows: Five hundred cc. of blood is placed in a flask and left in the ice box for twenty-four or forty-eight hours, after which the plasma is removed. A volume of a 5.4 per cent of dextrose solution in isotonic solution of sodium chloride equal to that of the removed plasma is added. The solution is then ready for use. It can be stored for from one to four days. The indications for its use are posthemorrhagic anemia and anemia of cardiac insufficiency. Hemoconcentration, shock, burns and hypoproteinemia constitute contraindications. The author transfused suspensions of blood corpuscles to 36 patients with posthemorrhagic anemia. The number of transfusions varied from one to eighteen. The amount for each transfusion varied from 100 to 500 cc. Corpuscle suspensions are tolerated better than total blood, for which they are a good substitute. The importance of administering cell suspensions to the wounded in war, as well as to the victims of various catastrophes among civilians, is emphasized.

Book Notices

Allergy in Practice. By Samuel M. Feinberg, M.D., Associate Professor of Medicine and Chief of the Division of Allergy, Northwestern University Medical School, Chicago. With the collaboration of Oren C. Durham, Chief Botanist, Abbott Laboratories. Cloth. Price, \$8. Pp. 798, with 36 illustrations. Chicago: Year Book Publishers, Inc., 1944.

The author has succeeded in writing a book in simple language, easy to read and to understand. The arrangement of the subject matter, using normal type in the presentation of the generally accepted material and smaller type for the more controversial aspects, is to be commended. The chapter on allergy to fungi is complete and includes Dr. Feinberg's special studies in this field. The chapter on pollen and pollen allergy was written by Oren C. Durham, whose many years of experience with botanic surveys in various sections of the United States makes his contribution a valuable addition to the book. Every section of the country is mapped botanically, a great help to practitioners in their respective localities. The major portion of the book is, as expected, devoted to the diagnosis and treatment of hay fever and asthma. This phase of the subject is fully covered. However, the other allergies are not neglected, fully one fifth of the book concerning itself with allergic coryza, urticaria and angioneurotic edema, the dermatoses, migraine and gastrointestinal allergy. Diagnosis and differential diagnosis are sufficiently detailed, and the treatment outlined is very practical. Each chapter is summarized. The bibliography is fairly complete. The use of the term adrenalin instead of the more appropriate epinephrine hydrochloride is an oversight. All in all, this book may be used profitably by both the beginner and the specialist in allergy and is recommended highly.

Pollinosis. Por Leopoldo Herranz Ballester, doctor en medicina, y Juan Victor Monticelli, doctor en ciencias naturales. Prólogo del Profesor Carlos Jiménez Díaz. Paper. Pp. 227, with 2 illustrations. Buenos Aires: Librería Hachette S. A., Palacio del Libro, 1943.

The authors, a physician and a botanist, present their closely integrated efforts over a period of four years in digesting the literature on pollen allergy, particularly from North and South America, and in carrying out comprehensive field, atmospheric and clinical pollen research. The book is not offered as a monograph on pollen disease but as a general preliminary study of the local Argentine problem, which will be followed shortly by a long series of articles which are listed by title in the bibliography. Emphasis is placed on the basic importance of recognition of the local qualitative and quantitative differences in the exposure of sensitive persons to pollens, and the authors strongly advocate the method of parallel clinical evaluation of pollen species while the seasonal and geographic incidence of these species is being determined.

The first half of the book is devoted to the anemophilous flora and air borne pollen of eight of the most populous provinces and territories of central Argentina as compared with similar data from other parts of the world. Three floral zones are mapped. Two of these are made by dividing the pampas region into an eastern area where rainfall is more abundant and a western area of scant rainfall. The Andean zone is a narrow strip between the dry pampas and the continental divide. Daily tests of atmospheric pollen concentration have been carried out in eleven cities over a three year period. The botanic data are embodied in numerous tables supplemented with condensed comments.

The second half of the book covers the results of clinical work in Argentina and stresses the regional characteristics of pollinosis as related to the botanic studies already made. In matters of skin testing and preseasonal, coseasonal and perennial treatment the technic described is much the same as that followed by American authors, but the stock combinations of pollen extract described in the section entitled "Desensibilización Específica" would hardly meet the approval of allergists in this country.

The practical value of this book to physicians of the United States and Canada is obviously limited by the relatively small number of allergic persons who change their residence from North America to Argentina or vice versa.

Homicide Investigation: Practical Information for Coroners, Police Officers, and Other Investigators. By LeMoyne Snyder, Medical Legal Director, Michigan State Police. With chapters by Captain Harold Mulbar, Chief of the Identification Bureau of the Michigan State Police, Charles M. Wilson, Director, Chicago Police Scientific Crime Detection Laboratory, and C. W. Muehlberger, Director, Michigan Crime Detection Laboratory. Cloth. Price, \$5. Pp. 287, with 116 illustrations. Springfield, Illinois & Baltimore: Charles C Thomas, 1944.

The object of this book is to aid policemen, coroners and other officials in the investigation of deaths from unnatural causes. Special and detailed attention is given to the proper examination where and when the dead body is first found. Information of essential significance may be lost and the solution of vital problems prevented if this first examination is not done in the right way. The language is suitable, and the illustrations are instructive and realistic. The book will be of great value to all who must investigate apparently violent deaths, including practitioners who may be called on to make examinations in such cases. "Never touch, change or alter anything until identified, measured and photographed. Remember that when a body or an article has been moved it can never be restored to its original position." This is the golden rule for investigation in cases of suspected homicide, but the principle has wide application.

Parálisis infantil en Colombia. Por Luis Betaneur Araugo. Tesis de grado presentada a la Escuela de medicina para optar el título de doctor en medicina y cirugía, Universidad de Antioquia, Facultad de medicina y ciencias naturales. Paper. Pp. 138. Medellín, 1942.

Sporadic epidemics of subacute but typical poliomyelitis have been observed during the last twenty-five years in Colombia. Epidemic outbreaks occurred in Colombia at the same time at which epidemics occurred in several other countries. An epidemic among children under the age of 12 years was observed in the departments of Cauca, Valle del Cauca, Antioquia and Santander del Sur between October 1939 and August 1941. The patients in the department of Valle del Cauca acquired the disease from contagion during their stay in the department of Cauca. The author points out the importance of passing national laws for control of the disease. The therapy used in the 1939 and 1941 epidemics consisted of a daily dose of potassium chlorate by the mouth for two or three consecutive weeks. The patients had also 5 cc. of antistreptococci serum daily up to a total dose of 20 cc. and a dose of 5 mg. of vitamin B every three days up to a total of 25 mg. The treatment had no effect on the course of the disease.

A Catalogue of the Medieval and Renaissance Manuscripts and Incunabula in the Boston Medical Library. Compiled by James F. Ballard, Director, Boston Medical Library. Cloth. Privately printed. Pp. 216. Menasha: George Banta Publishing Company, 1941.

The growth of the collection in the Boston Medical Library of incunabula and manuscripts is described in the introduction by Henry R. Viets, librarian. The compiler of the catalogue, James R. Ballard, has just completed fifty years of service to the library. He has had "a lifelong interest in manuscripts and the early printed medical books." Mr. Ballard lists 674 incunabula and 52 manuscripts. The list appears to include some edition or other of nearly every book of medical interest published before 1501. Scholars, librarians and bibliographers will appreciate the appended indexes of subjects, names, manuscripts, printers, publishers and patrons as well as the concordances to the lists of incunabula by Stillwell, Klebs and Osler. The illustrations are of singular interest. Special congratulations are extended to the Boston Medical Library and to Mr. Ballard on this contribution to bibliographic scholarship.

Elimination Diets and the Patient's Allergies: A Handbook of Allergy. By Albert H. Rowe, M.D., Consultant in Allergic Diseases, Alameda County Hospital, Oakland, California. Second edition. Cloth. Price, \$3.50. Pp. 256. Philadelphia: Lea & Febiger, 1944.

The author states in the preface that the purpose of this book is twofold: "first to emphasize the importance of food allergy and, second, to discuss the other causes of clinical allergy with present day methods for their diagnosis and control." The second of these stated purposes is taken up in the first hundred and fifty pages of this book. The work is poorly done. The general physician without special training in allergy would have a confusing and incomplete picture of the allergic conditions and their methods of diagnosis from this part of the

book. The physician with only a limited but guided experience in allergy would have no need for the superficial remarks on many subjects contained in this first half of the book.

To clarify this statement are the following: Only three pages are given to contact dermatitis, its causes and methods of diagnosis; the entire subject of "sensitization" covers only one page; injectants, including serum sickness, drug allergy and vaccines, two pages; physical allergy, a brief paragraph; bronchial allergy and allergic bronchitis, eight pages; seasonal and perennial hay fever is treated in three pages. In a book with this title, the author might well have limited himself to a presentation of the principles of allergy in one hundred pages and presented the rest of his limited subject in the additional hundred pages.

The second part of this book, as in the first edition, is devoted to a thorough presentation of many useful elimination diets to fit a variety of diagnostic needs, together with sample menus and many useful and practical recipes. Additional recipes, information regarding various food components in mixed food preparations and much other useful information are contained in a loosely organized fashion in the final fifty pages of the book. The second part contains excellent material and much practical information for the reader who is able to organize such data.

Principles and Practice of Aviation Medicine. By Harry G. Armstrong, M.D., F.A.C.P., Colonel, Medical Corps, United States Army. Second edition. Cloth. Price, \$6.50. Pp. 514, with 87 illustrations. Baltimore: William Wood & Company, 1943.

The second edition of this now universally accepted textbook on aviation medicine has no change in the purpose, scope or arrangement of the subject matter from that in the first edition, which has been reprinted four times. Colonel Armstrong is recognized as an authority on aviation medicine. He has been largely responsible for keeping development in aviation medicine concurrent with development in aviation industry. This edition will undoubtedly increase the widespread interest in aviation medicine in the United States and abroad. Information has been added on the effects of centrifugal force and on the emotional reactions to flight. The importance of taking oxygen at altitudes as low as 5,000 feet at night in order to avoid reduction of night vision is stressed, and diagrams of the correct and incorrect manners of looking at objects in dim illumination are presented. The main sections of the book are those that deal with the selection and care of the flier, physical factors in flight, anoxia in aviation, altitude sickness, mechanical effects of decreased atmospheric pressure, including acrobolism and ear distress, pressure cabins, speed and acceleration and emotional reactions to flight. Naturally, a considerable portion of recent work in aviation medicine is classified as confidential and will not be available for publication until after the war; however, the inclusion of the unrestricted information available and the revision of several chapters, with addition of a number of illustrations and tables, are sufficient to make it mandatory for all persons interested in aviation medicine to read this book carefully.

Occupational Lead Exposure and Lead Poisoning. A Report Prepared by the Committee on Lead Poisoning of the Industrial Hygiene Section of the American Public Health Association. Paper. Price, 75 cents. Pp. 67. New York: American Public Health Association, 1943.

For some time there has been misconception of the etiologic factors, diagnosis, control and treatment of lead poisoning, as the result of enthusiastic publication of isolated procedures. This committee report is a practical authoritative statement on occupational lead exposure and poisoning which will clarify the situation. It is divided into five parts:

1. The recognition of hazardous lead exposures. This section covers the occurrence of lead poisoning in industry and the recognition and measurement of the exposure.
2. Safe limits of occupational lead exposure. This includes safe limits as shown by air analysis and clinical tests of blood and urine of workmen exposed.
3. Control of occupational lead exposure. This is a description of control by engineering features and the steps required in medical supervision of workers exposed to lead.
4. Occupational lead poisoning. A rather detailed description is given of the diagnostic procedure plus the management and treatment of lead poisoning.

5. Appendix and classified bibliography. The committee has not attempted to discuss completely all controversial points but has included this comprehensive bibliography, which gives the reader an opportunity to refer to any source material on specific points.

Introduction to Exceptional Children. By Harry J. Baker, Ph.D., Director, Psychological Clinic, Detroit Public Schools. Cloth. Price, \$3.50. Pp. 496, with illustrations. New York: Macmillan Company, 1944.

By "exceptional children" the author means not only the physically or mentally handicapped but also those in the outer ranges of normal, such as the excessively tall, unusually strong or specially gifted. Part I of the book correlates the education of the exceptional child with the purposes of all education, namely training for "self realization," "human relationships," "economic efficiency" and "civic responsibility." Part II is devoted to the problems of children with visual, auditory, lingual and orthopedic defects. Part III considers the subnormal and the intellectually superior. Part IV deals with neurotic behavior abnormalities, and the following two sections again take up the general problems of the educationally retarded and the difficult child. Obviously, so great a variety of topics can be dealt with only superficially in a single book. Unfortunately too, for a volume intended as a textbook the style is frequently slipshod (p. 71: "Louis Braille . . . lost his eyesight with a knife at the age of 5 years while imitating his father, who was a saddler by trade") and too many careless statements are made (p. 51: "Guy de Maupassant . . . had diplopia due to paralysis of the extraocular muscles, and his death resulted from the general paresis caused by it"). Nevertheless, the material is well organized, and certain sections such as those on visual defects are clear and informative. Behavior is approached dynamically and in relation to physical, social, economic and other factors as well as purely pedagogic influences. The book should serve well as an introductory textbook for students of elementary education; perhaps later revisions and additions will expand its usefulness to social workers, psychologists and physicians.

Virus Diseases in Man, Animal and Plant. By Gustav Siefert. A Survey and Reports Covering the Major Research Work Done During the Last Decade. [Translation by Marion Leo Taylor, Ph.D.] Cloth. Price, \$5. Pp. 332, with 7 illustrations. New York: Philosophical Library, Inc., 1944.

In 1938 this book appeared in its original German edition. In its 221 pages it filled a definite need for a concise digest of the general characteristics of viruses and specific consideration of the different diseases. A brief chapter on methods pointed out the basic technics. This book has now been published as a translation into English with the added endorsement that it is published on recommendation of the National Research Council. No attempt has been made to produce a new edition revised so as to include studies since 1938. Probably the present volume will serve as a source book for reference. It is well annotated. The English of the translation is, however, unbelievably awkward. Much of the German terminology and construction are preserved to the point that whole sections are ridiculous. There are numerous mistakes in spelling, and the proof reading has been badly done. It is shameful that a book of such inherent value should have been so mistreated.

Laboratory Methods of the United States Army. Edited by James Stevens Simmons, B.S., M.D., Ph.D., Brigadier General, United States Army, and Cleon J. Gentzkow, M.D., Ph.D., Colonel, Medical Corps, United States Army. Approved by the Surgeon General of the United States Army. Fifth edition. Fabrikoid. Price, \$7.50. Pp. 823, with 111 illustrations. Philadelphia: Lea & Febiger, 1944.

The fifth edition of this well established work on laboratory technic indicates further progress in a book that has had a long and enviable record. The first edition appeared during the first world war, and other editions have been issued from time to time since that date. The present volume represents a composite work in which many distinguished investigators have cooperated. Every phase of clinical pathology is covered. The directions are explicit, the illustrations, particularly those on the distribution of tropical disease, most informative. References to the periodical literature which accompany the various chapters indicate that the work is quite up to date.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HYPERSENSITIVITY TO SULFONAMIDE

To the Editor:—I have been using a combination of powdered sulfanilamide and sulfathiazole for nasal insufflation in the treatment of head colds and sinus conditions. Is there any danger from prolonged therapy? What are the possibilities of sensitization to the sulfonamides? What tests determine whether or not a patient is sensitive to sulfonamides prior to their internal administration? In the event of sensitivity how can a patient be desensitized in order that the drug may be administered? Does sensitization eventually disappear if the patient abstains from using the drug over a period of time?

M.D., New York.

ANSWER.—In discussing the effect of topically applied sulfonamides on human tissues, a distinction must be made between reactions resulting from toxicity of the compounds and a true type of induced hypersensitivity. This distinction is not too apparent at times. There is danger that a localized and, more rarely, a generalized type of hypersensitivity to sulfanilamide, and more particularly to sulfathiazole, may result from prolonged nasal insufflation of these compounds. Other than these, possibilities there does not appear to be any danger, although some authorities are opposed to the use of solutions of sodium sulfathiazole for such purposes because of the possibility of producing tissue necrosis. Leftwich has recently proposed the thesis that hypersensitivity to the sulfonamides is an allergic reaction similar to serum sickness (An Intradermal Test for Recognition of Hypersensitivity to Sulfonamide Drugs, *Bull. Johns Hopkins Hosp.* 74:26 [Jan.] 1944). Therefore, hypersensitivity to the sulfonamides may be detected by injecting intradermally serum which is obtained from a patient who is receiving a sulfonamide in doses so that a serum level of 2 mg. or more per cubic centimeter is present. An immediate type of reaction will be obtained in the patient who is hypersensitive to the drug. Before such a test can be accepted by the profession, confirmation of this work is necessary. A more commonly used procedure in patients suspected of being sensitive is to administer 0.5 Gm. of the drug by mouth and keep the patient under observation for ten to twelve hours. Patients who are sensitive to the compound will exhibit such reactions as fever, skin eruptions and nausea and vomiting. In the event that a patient does exhibit signs of sensitivity to one sulfonamide, it would be more practical to try another sulfonamide. While desensitization to a sulfonamide has been attempted, it is a time consuming and dangerous procedure. This has been accomplished, according to some reports, by the oral administration of a small dose of the drug, and then increasing the doses gradually. In general, real hypersensitivity to a particular sulfonamide has been shown to persist for as long as two to three years.

MANAGEMENT OF PATIENTS WITH AURICULAR FIBRILLATION AND CONGESTIVE FAILURE

To the Editor:—A patient has chronic bronchial asthma, is 63 years old and has developed congestive heart failure. His pulse was rapid but regular until he was fully digitalized; then his heart began fibrillating, but his signs of congestion began to improve. On discontinuing digitalis the pulse became regular but signs of congestion increased. The only other therapy has been four doses of mercuriprin. If I continued digitalis therapy in spite of the fibrillation which developed would the ventricular rate, which is rapid even during fibrillation, slow down and become more regular? Incidentally, the fibrillation was occasionally replaced by short periods, say thirty seconds, of slow, regular pulse. The only sign of digitalis toxicity was partial loss of appetite.

Bernard Marcus, M.D., Bronx, N. Y.

ANSWER.—It is impossible to answer the specific question raised, but the principles underlying a proper answer can be outlined in detail. The ranges of digitalizing doses of digitalis and of maintenance doses are now recognized to be wider than has hitherto supposed. An occasional patient will become digitalized on as little as 5 cat units, will require only 2 units a week as a maintenance dose and will become toxic if 3 units a week is given. On the other hand, an occasional patient can take as much as 30 units during the course of a massive dose technic of digitalization and will require 2 units a day as a maintenance dose and may not show toxic signs on 3 units a day.

It is impossible to say whether the patient described had too much or too little digitalis, but it would seem probable that it was the former. Without an electrocardiogram it would be clinically impossible to determine whether during the periods of fibrillation his rapid ventricular rate was the result of beats all of which were of supraventricular origin or some of which were ventricular extrasystoles. Furthermore, the ST and T changes in the electrocardiogram would give some clue as to possible digitalis intoxication. It should be added that a few patients develop serious toxic digitalis rhythms without even a loss of appetite as a clinical guide to the nature of the trouble.

A relatively small initial dose of digitalis may be given at a time when the patient has had none for some three weeks (approximately 5 cat units). If the signs of congestion begin to improve, 1 unit every other day might be tried as a maintenance dose, modifying this as seems indicated by the progress of the congestive heart failure. If there is no evidence of clinical improvement eight hours after the first dose of 5 cat units, 2 or 3 cat units might be given every twelve hours until the patient begins to improve. A diuresis is one of the frequent early signs of clinical improvement. When this begins, the large doses should be discontinued immediately and smaller ones started, their frequency to depend on the total amount given by the foregoing technic. If, for example, a diuresis begins after 11 cat units has been given in three divided doses, it is probable that the patient cannot tolerate 1 cat unit a day but will do better on something like 5 a week. If, however, a total of 23 cat units has been given in seven divided doses before any evidence of improvement occurs, it is probable that he will require more than 1 cat unit a day as a maintenance dose—probably 9 or 10 units a week.

It is not likely that the patient will develop fibrillation if the digitalis is administered as described. However, if this does occur before signs of clinical improvement occur, two alternatives are open: Maintenance doses of quinidine may be given simultaneously with the digitalis therapy or another preparation may be tried such as squill or strophanthin, of which the former would seem to be the method of choice.

DEXTROSE CONTENT OF POSTMORTEM BLOOD

To the Editor:—For how long after death and how accurate are blood sugar determinations obtained from cadavers?

M.D., Massachusetts.

ANSWER.—The dextrose content of postmortem blood is gradually reduced from the time of death. Many factors influence the rapidity of this reduction, such as temperature, enzymatic action and pH of the blood. Hill estimated that at 37.5 C. the rate of reduction lies between 10.1 and 16.5 mg. per hour; with an average of 12.8 mg. in 100 cc. of postmortem blood. At 27.5 C. the reduction rate was between 4.14 and 6.94 mg. per hour, with the average 5.98 mg.

Disease processes also influence glycolysis. For example, in anemia and leukopenia disorders glycolytic action is retarded, whereas in the leukemias and erythremia there is an acceleration of the process. Furthermore, the dextrose content of postmortem blood at the time of death varies in different conditions. High values are occasionally found in asphyxia, shock, acute coronary occlusion, increased intracranial pressure, diabetes and certain poisons, especially those causing anoxemia. Low postmortem blood sugar is found in starvation, insulin shock, certain liver diseases, such as acute yellow atrophy, and in debilitated and cachectic subjects.

Under the circumstances it is not possible to express an opinion as to the fixed time interval when glucose will disappear. The sugar has been found thirty-six or more hours after death and in favorable cases probably persists until decomposition destroys it.

It is generally recommended that the blood be taken from the left side of the heart as soon as possible after death. Hypoglycemia may be suspected if the tests fail to show dextrose or the substance is present in minimal amounts within two hours after death.

Generally considered, it is the writer's opinion that these tests are of limited value in legal medicine from the point of view both of the cause of death and of the estimation of the postmortem interval.

For a more comprehensive discussion of the subject with the literature, the inquirer is referred to the article on the significance of dextrose and non-dextrose reducing substances in postmortem blood by E. V. Hill in the *Archives of Pathology* 32:452 (Sept.) 1941.

ALLERGY AND ALBUMINURIA

To the Editor:—I have heard recently of studies on the relationship of allergy to albuminuria. A patient is sensitive on scratch and intradermal tests to a large variety of foods, household contacts and grass, tree and plant antigens (26 out of 45 tested) although he now has only fall hay fever. He had stubborn eczemas in childhood, and is still prone to contact dermatitis. His albuminuria, which began after an attack of massive hematuria, is still quite heavy, eleven months later. He has had several flare-ups of hematuria during the past year following physical strains or colds. However, his blood pressure is never over 130/90 and was 124/84 five years ago. He has never had any anasarca or other manifestations of glomerulonephritis. His plasma proteins, sedimentation rate and nonprotein nitrogen are all normal. Would I be justified in attempting to desensitize this patient with streptococcus vaccine on the basis of attributing his nephritis to abnormal sensitivity to *Streptococcus haemolyticus*?

M.D., Indiana.

ANSWER.—In acute allergic reactions, such as serum sickness, a severe prolonged attack of asthma or following an acute anaphylactic reaction, albuminuria is apt to occur as part of the general clinical picture. In the ordinary atopic manifestations, such as rhinitis, asthma or eczema, albuminuria is certainly not found with any degree of frequency. It has been shown experimentally in animals that kidney inflammation may result from bacterial sensitization. Presumably the same phenomenon might occur in man. Bacterial allergy, however, is difficult to prove in the individual case, and in the particular instance cited no data are presented which would give evidence for that possibility. If a focal infection, such as infected tonsils or teeth, is present the proper procedure would be to eliminate the infection. Even when a source of bacterial allergy can be proved, "desensitization" with the bacteria or their products still remains a highly experimental procedure.

PSYCHOMETRIC RATING TESTS

To the Editor:—Could you give me information concerning suitable psychometric tests for adults? When time is limited, the Stanford revision of the Simon-Binet test and some of the other longer ones are not appropriate. I have been using the Kent test with fairly good results. Recently its reliability was questioned by some of my associates; for instance, it was pointed out that the answer to question 20, whose picture is on a two cent stamp? Washington's, is wrong. Of course that may not affect the validity of the rest of the questions and answers. I wonder if there is a revised edition of this test which has been found useful because of its brevity and easy computation. Will you comment on the reliability of this test? Thank you for references on this and other short tests.

M.D., Iowa.

-ANSWER.—The reliability of the Kent EGY is fairly good; that is to say, correlative reliability is not as good as one would like to have it, but it is sufficiently high to obtain trustworthy psychologic ratings. Its greatest limitation is that it is essentially an information test, thereby being a handicap to persons who have had little formal schooling. Several army units have used it and report satisfactory results.

For general purposes, the short form of the Stanford Revision of the Binet-Simon test is most satisfactory.

PREPARATION OF PERTUSSIS VACCINE

To the Editor:—Could you give me information on any difference in prophylactic value of whooping cough vaccine made with human blood and that made with animal blood?

James C. Overall, M.D., Nashville, Tenn.

ANSWER.—Whooping cough vaccine is used chiefly as a preventive, injected preferably soon after the seventh month of life. Vaccine made with human blood is not "washed" and is reported to contain all the products of the micro-organism. Other vaccines made with horse, sheep, bovine or goat blood is washed to rid it from the alien (animal) protein, injection of which might otherwise sensitize the child or, on subsequent injection of any biologic preparation prepared with the homologous blood, might elicit local or systemic reactions of one kind or another. According to some investigators, "washing" weakens the antigen.

BOXING, TRAUMA AND EPILEPSY

To the Editor:—A young man who has been a professional boxer for several months was placed in 4-F by his Selective Service board. The reason for his classification was that he had epilepsy, and it is my opinion that he should not be in that particular professional sport. I am writing to ask what the consensus is on that subject.

M.D., Wisconsin.

ANSWER.—On theoretical grounds the profession of boxing is a poor occupation for an epileptic person. Frequent blows on the head cannot be good for the integrity or the function of the brain, as witness the condition called "punch drunk." However, it is surprising but true that an epileptic patient may experience skull fracture and severe brain concussion without exacerbation of his seizures.

PROBABLE TRAUMATIC URETHRAL STRICTURE WITH
RECURRENT EPIDIDYMITIS

To the Editor:—A man aged 27, of unusually rugged type, doing the hardest kind of work in the oil fields, has just been discharged from the hospital (two days) with the diagnosis of gonorrheal epididymitis. He has three healthy children; the youngest, 14 months, does not suggest syphilis. He denies venereal disease and, after talking to him and his wife, I am inclined to believe this. There is no urethral discharge; therefore there is nothing to examine there. The hospital chart states "No laboratory work necessary," so I do not know on what the diagnosis was based. The patient gives the following history: At 10 years of age he fell astraddle of something and passed blood for a few days. At 14 years of age he began to have attacks of swelling and pain in the scrotum, apparently involving the epididymis, from his description. He has had such attacks for twelve years up to the present time on an average of once a month, he says. Fourteen months ago his wife was delivered by cesarean section because of placenta previa. To avoid another pregnancy the patient had vasectomy done a year ago. He has continued to have his attacks of pain and swelling in the scrotum, and the present is the most severe attack he has had. The right testis is much swollen—about the size of a goose egg—and is moderately tender. The epididymis can be felt, is enlarged and is exquisitely tender. The swelling of the testis is not a hydrocele. He has one enlarged inguinal gland on the left. His temperature is 100 F. The white blood count is 6,000. He had mumps when a child. The mild attacks at frequent intervals have continued since the vasectomy. On account of these recurring attacks I would be inclined to advise removal of the right testis but for the fact that, as he tells, two of the mild attacks have been on the left side. To palpation the left testis is normal at present. One detail that puzzles me is why, if this is a gonorrheal infection arising from infected seminal vesicles, it should continue after vasectomy with the same frequency as before.

M.D., California.

ANSWER.—The diagnosis made on the discharge from the hospital in this case seems highly questionable. In the first place, the diagnosis was not made by following any scientific examination, and the clinical history as presented here is not one of a chronic gonorrheal infection. It would appear that the most pertinent fact in this man's history is that he had a straddle urethral injury ten years ago. The complication resulting from such trauma is, of course, traumatic urethral stricture. One of the most common causes of spontaneous intermittent epididymitis is urethral stricture. On the basis of the available facts this man most certainly should have a careful investigation of his anterior urethra for stricture and careful investigation of his prostate and seminal vesicles for infection.

To be sure, an adequate vasectomy should protect the epididymis from descending infection, but in the presence of continued epididymitis one must think of the possibility that the vas was not resected on one or both sides or that residual infection remains on one or the other epididymis even after the subsidence of acute local symptoms.

Under no consideration should orchiectomy be thought of in a case like this, but occasionally there are indications for epididymectomy under similar circumstances.

THE CHEMICAL REACTION OF PERSPIRATION
ON PEARL ARAGONITE

To the Editor:—Relative to the answer given to Dr. Putnam's inquiry as to the effect of skin secretions on pearls (May 20, 1944 issue of The Journal) I wish to state that an erroneous statement is made when it is said that perspiration will not harm pearl aragonite. During the past five years, as director of the Bureau of Natural Pearl Information, an organization supported by forty retail and wholesale jewelry firms, I have handled, inspected, and tested thousands of pearl necklaces of both cultured and natural origin. Among the many necklaces tested, samples of pearls have been found which had lost their original sphericity through strictly chemical processes. This particular problem was first investigated when I was an incumbent on the Pearl Fellowship, Mellon Institute of Industrial Research, 1938-1940. To cite a simple experiment, one has only to immerse a pearl necklace in distilled water and leave it there for a few days. Carbon dioxide will be absorbed from the air, with the result that the distilled water will become mildly acidic. Under certain conditions the pH of the water may get to be as low as 5. On removing the pearls after their submersion, one finds that they are completely white, having lost their original luster and orient. Solution of the calcium carbonate of the pearl has ensued as a result of chemical reaction. Since distilled water is not perspiration, let us consider the analyses of human sweat, as made by Mosher (*J. Biol. Chem.* 99:781, 1932) and by Vass and McSwiney (*J. Soc. Dyers & Col.* 46:190, 1930). Sweat was obtained from 4 obese women and the pH of each sample determined. Mosher found the pH to be 5.52, 5.48, 5.39 and 5.77 respectively. Since a neutral solution is taken as pH 7, the figures here given are definitely on the acid side. Vass and McSwiney collected 583, 540, 470, 440, 534, and 498 cc. of perspiration from as many individuals. The pH of these solutions was 5.42, 5.65, 5.02, 5.18, 5.17 and 5.47. The pH values are again those of an acid medium. These authorities give complete chemical analyses of the perspirations examined and should be consulted for the exact acid constituents found. Incidentally, the amount of sweat exuded by stout persons may be twice that formed by normal individuals under the same conditions. The evidence presented here is the real answer to Dr. Putnam's inquiry.

ABUSE OF REST AS A THERAPEUTIC MEASURE FOR PATIENTS WITH CARDIOVASCULAR DISEASE

CHAIRMAN'S ADDRESS

TINSLEY R. HARRISON, M.D.
DALLAS, TEXAS

Rest of injured parts and of diseased bodies is probably the oldest and most valuable of all methods of treatment, with the possible exception of psychotherapy. Nevertheless we seem from time to time to forget that this therapeutic method—like all others—may lead to untoward results when utilized either injudiciously or excessively. Within the past three decades there has developed a tendency to regard prolonged rest in bed and complete abstinence from normal economic activity as the sine qua non of the proper management of the more serious forms of heart disease. My purpose in the present report is to review certain experimental and clinical observations which seem to indicate that this concept may be unsound.

During the eighteenth and nineteenth centuries, while the basic framework for our present understanding of heart disease was being fashioned, little emphasis was placed on the desirability of rest as it is now employed. Such astute observers as Withering¹ and Heberden² scarcely mentioned it in their works. Indeed, Heberden cites a patient with angina pectoris "who set himself the task of sawing wood for half an hour every day and was nearly cured." Similarly, William Stokes³ utilized graduated exercise for patients with various cardiac disabilities. His contemporaries were apparently not in entire agreement with him on this point, but if any of them advocated prolonged and rigid rest in bed as a method of treating heart disease I am not aware of it.

In view of the plans of therapy often employed at present in the treatment of diseases of the coronary arteries, the personal case histories of two famous physicians are of interest. In 1773 John Hunter had, at the age of 45, an attack of severe epigastric pain. This could have represented myocardial infarction, but from the description given by his brother-in-law Everard Home⁴ the diagnosis seems doubtful. In 1785 he began to have severe anginal attacks at rest and within a few weeks experienced more prolonged periods

of pain which were in all probability caused by myocardial infarction. From this time until his sudden death in 1793 he had numerous seizures induced by effort or by emotion. At autopsy he had extensive disease of the coronary arteries, calcification of the aortic valves and two large scars which presumably represented old infarcts. During his later years he continued to be quite active, did much of his best work and apparently never remained in bed for any long period of time. Nevertheless he lived at least eight and possibly twenty years after the onset of symptoms indicating serious heart disease. Is one to assume that he would have lived longer if he had lived the life of semi-invalidism to which we so often condemn the modern patient with "coronary symptoms"? Would his happiness have been decreased or increased by such a regimen?

The case history of Sir James Mackenzie⁵ is perhaps even more striking. He began to have minimal attacks of angina of effort in 1907 and had severe attacks which probably represented infarction in 1908. He lived until 1925 and during this time had many seizures of mild pain and several severe and prolonged attacks. The autopsy revealed extensive atheroma of coronary branches and several healed infarcts. During the first fifteen years after the onset of his anginal attacks he continued to play golf until finally forced to desist by the progressive decline in exercise tolerance. Even so he led an active and useful life for seventeen years after myocardial infarction and, as far as I am aware, never spent more than a few days in bed at any time. Are we justified in assuming that he would have lived longer or enjoyed more happiness if he had been forced to remain in bed for several months after his infarction and if his permanent plan of living had been drastically restricted? Was the father of modern cardiology a poor therapist in regard to his own case? Questions such as these which permit no dogmatic answers should lead one to adopt an open mind regarding the desirability of prolonged and rigid rest in patients with cardiac disorders.

My own interest in the possibility that rest might be abused as a therapeutic method began in 1927, when I had occasion to visit a number of European clinics and to observe that patients with congestive failure were often allowed to sit up in chairs and to walk about the wards. At the time this seemed to be a shocking practice, but doubts so aroused were later strengthened when I learned that Sir James Mackenzie had handled patients in a similar manner.⁶ During the next several years a large group of patients—both Negro and white—were under observation in the cardiac clinic at the Vanderbilt University Hospital. The scarcity of ward beds for Negroes forced one to treat all except the most urgent cases of heart failure in this race in the out-

patient department, while most of the white patients were admitted to the wards as soon as evidences of heart failure were observed. After several years had elapsed I began to gain the impression that the number of old friends and familiar faces was greater in the Negro than in the white group. The matter was never studied statistically, but a little later the same general problem was approached somewhat differently by Williams and Rainey,⁷ who analyzed the records at the Vanderbilt University Hospital for the immediate causes of death as found at autopsy in the patients with heart diseases during a ten year period. These authors found that relatively few patients were dying of an uncomplicated cardiac failure and that the three great causes of death in patients who were admitted to the hospital with this disorder were infarction of the lungs, pneumonia and uremia. Their work suggested that at least some of the chief causes of death in such patients represented conditions which tended to develop under a state of complete rest and which might have been to some extent prevented by mild muscular activity.

Following the studies of Williams and Rainey, observations were carried on during a period of several years, first at the Vanderbilt University Hospital and later in the North Carolina Baptist Hospital. In these studies an attempt was made to divide alternate cases of congestive failure into two groups, "three week cardiacs" and "three day cardiacs," the designations referring to the duration of time after admission in which a period of rigid rest was enforced. Although several hundred patients were so studied, the groups were not large enough to warrant statistical analysis, since such variables as age, sex, race, etiologic factors, severity of congestive failure and complicating diseases made accurate comparison impossible. The only information which came from the study was the conclusion that the "three day cardiacs" were happier patients and that no evidence of higher mortality was found in this group.

During the fifteen years in which the effects of rest have been studied in subjects with congestive failure, a large number of patients with myocardial infarcts have been observed, and I have been impressed with the frequency of a second myocardial infarct as well as the high incidence of pulmonary infarction occurring after two or more weeks of rigid bed rest. However, there has been no control group who have been allowed to follow the self-prescribed treatment of John Hunter and Sir James Mackenzie, in terms of forsaking the bed and resuming activity as soon as the subjects desired it. Hence, here again no definite conclusions can be drawn as to whether prolonged and rigid restriction of activity increases or decreases mortality. However, one point has become increasingly clear and that has been that the incidence of postinfarctional cardiac neurosis is decidedly greater in those subjects who have been kept in bed for several months.

The clinical studies which have been described have been inconclusive because of the difficulty in controlling all of the many variable factors. For this reason an experimental attack on the problem was undertaken two years ago at the Bowman-Gray School of Medicine in conjunction with Dr. Wilbur C. Thomas.⁸ The work has been reported in detail elsewhere and will only be summarized here. Standardized myocardial injury was

induced in rats by burning the surface of the left ventricle, and the animals were subjected to various types of postoperative care. Those rats which were treated by extreme limitation of muscular movement through the use of cages so small as almost to fit the animal and to prevent turning around exhibited much higher mortality than did the controls who were allowed to wander at will in rat cages of the usual size. (It is recognized, of course, that such an experiment is more analogous to the use of the strait-jacket than to enforced bed rest in patients.) When the spontaneous activity of rats was studied by the use of the optional treadmill, it was found that most of the animals voluntarily chose to take as much exercise per day within five to seven days after cardiac injury as they had been undertaking during the preceding control period of one or two weeks. Observations were then made on rats in which muscular activity was enforced by making the animal swim for periods of ten to fifteen minutes several times daily. It was found that if one waited as long as even a few days after cardiac injury, such relatively strenuous muscular exercise did not cause any significant increase in the mortality. Obviously, this does not mean that patients with acute myocardial injury should be allowed strenuous exercise within such a short period, because the rate of healing processes in the heart is considerably faster in the smaller animal than in man. However, the results did appear to be fairly conclusive in indicating that under controlled experimental conditions excessive restriction of muscular activity was harmful, while the return to normal activity within a few days seemed to exert no detectable injurious effects. The results, therefore, support the clinical impression previously arrived at on the basis of less carefully controlled observations and have led me to question seriously the validity of current methods of handling patients with the graver forms of heart disease. Final conclusions are not justified until further observations on patients have been made, but in the meantime one may perhaps venture to enumerate certain theoretical considerations concerning the advantages and disadvantages of prolonged and rigid rest in bed.

Among the hypothetical advantages of prolonged rest in bed following myocardial infarction are the following:

1. Decreased liability to cardiac rupture. This consideration is probably especially important during the first two weeks, because most instances of rupture occur within this period.

2. During circulatory collapse the upright position aggravates cerebral anoxia. However, in most patients circulatory collapse of serious degree has disappeared within the first week or two and likewise, from this standpoint, there is rarely need for rigid rest of more prolonged duration.

3. One might expect that prolonged rest in the recumbent position would lead to a firmer and smaller scar. This, however, can be questioned because the cardiac work per beat is probably no greater and may be somewhat less in the sitting than in the recumbent posture, the decline in blood pressure in the recumbent position being usually at least counterbalanced by the increased stroke volume in this posture.

Among the theoretical disadvantages of prolonged rest in bed in patients with myocardial infarction are the following:

1. Given a tendency toward the development of congestive heart failure, edema of the lungs will tend to occur more readily in the recumbent position.

7. Williams, R. H., and Rainey, J.: Cause of Death in Patients with Congestive Heart Failure, *Am. Heart J.* 15: 385-394, 1938.

8. Thomas, W. C., and Harrison, T. R.: The Effect of Artificial Restriction of Activity on Rats with Experimental Myocardial Injury, *Am. J. M. Sc.*, to be published.

2. Rigid restriction of activity reduces flow of blood to a minimum and may tend to favor development of thrombi either in the venous system with subsequent pulmonary infarction or in the arteries and more especially in branches of the coronary system other than the ones originally affected. Hence, both pulmonary infarction and a second myocardial infarction are frequently observed in patients subjected to unusually prolonged and rigid rest.

3. "Hypostatic pneumonia" is especially apt to occur in elderly subjects who remain in bed over a long period of time.

The discussion thus far has been centered around the physical consideration of prolonged rest and indicates that there are theoretical reasons both for and against such a method of treatment. However, not only the somatic but also the psychologic factors need to be taken into account. Once an individual has recovered from the initial phases of myocardial infarction and has reached an asymptomatic state, the normal desire to resume activity occurs and each additional week of complete rest can usually be achieved only at the expense of increased urgency on the part of the physician. Such a sequence of events leads many patients to exaggerate to themselves the seriousness of their physical condition and all too frequently results in the development of a postinfarctional anxiety state. It therefore is common to observe rather severe manifestations of "cardiac neurosis" induced not so much by the "heart attack" but by the physician's management of the heart attack. One sees many patients who live through years of psychic invalidism brought about as the result of the physician's insistence on excessive caution during a period of many months. Even if we could be certain that such excessive caution would prolong life in an occasional patient—and there is grave doubt concerning this—there still remains the question as to whether the objective so achieved merits the unhappiness produced in a larger group of patients by rigid restriction.

SUMMARY

A review of some recent experimental evidence and certain clinical considerations leads to the following general conclusions:

1. Extreme restriction of body movement causes increased mortality in animals with experimental myocardial injury.

2. There is no proof that rest in bed carried out for many weeks after symptoms have disappeared is of value in the physical management of the patient with congestive failure, angina pectoris or myocardial infarction. The available evidence, while perhaps not conclusive, points to the contrary, and more especially so if the recumbent posture is enforced while the patient is kept in bed.

3. From the psychic standpoint there is a definite disadvantage in the enforcement of a rigid regimen after the acute phase of the illness has subsided.

4. Until more definite information is available, the following tentative suggestions are offered for a plan of treatment which obviously requires modification according to the status of the individual patient:

(a) Persons with congestive heart failure should be allowed out of bed for several hours a day, as soon as severe dyspnea at rest has subsided.

(b) Following myocardial infarction, recumbency should not be prescribed for a longer period than two to three weeks after the more acute and alarming

symptoms have subsided. The recumbent position should not be enforced on patients who are more comfortable sitting. Other things being equal, it would appear wise to allow elderly patients out of bed sooner than younger ones.

(c) Rest in bed for more than a day or two at a time probably has no place in the treatment of angina pectoris except in those patients who are especially liable to develop in the immediate future myocardial infarction, as indicated by increasingly frequent and prolonged attacks at rest.

(d) In all patients with the severe forms of heart disease activity should be kept below the symptomatic threshold, i. e. should be less than that amount which induces dyspnea or pain.

THE ABUSE OF REST IN OBSTETRICS

NICHOLSON J. EASTMAN, M.D.

BALTIMORE

There are doubtless many ways in which rest may be abused in obstetrics and gynecology, ways of clinical import. But in view of the critical times through which our country is passing, it would seem particularly appropriate to consider two abuses of rest which not only bear on the health and happiness of every married woman but carry also far reaching implications in regard to the present and future welfare of our nation. I refer, first, to the abuse of rest as it affects pregnant women in industry and, second, to the abuse of rest of the female reproductive organs as it pertains to so-called "child spacing."

It has been estimated that about 18 million American women are employed today in industry, or some 36 per cent of all our women of 15 years and over. Of this group $6\frac{1}{2}$ to 8 million, or 13 to 16 per cent of all women, are being utilized by war industries alone (Hesseltine¹). Since more than 50 per cent of the women employed are married,² a substantial number of pregnancies is to be expected. But just what the actual incidence of pregnancy may be among these women is difficult to ascertain with any degree of precision because of the rapid turnover of workers, particularly if pregnancy occurs, and also because early gestations may be concealed and even denied; moreover, the statistics vary widely in different establishments. In 1941 one large industrial concern employing 20,000 women reported an annual incidence of 72.8 pregnancies per thousand women workers.² Pregnancy rates reported by some firms are much lower than this and range upward from 15 pregnancies per thousand women workers annually. Even, however, if the very minimal figure obtainable is used, it would appear that some quarter of a million women engaged in industrial work become pregnant in the course of a year, and the actual number may well be several times this.

The problems which would be presented by pregnant women in industry were anticipated by several

agencies shortly after Pearl Harbor. Thus in July 1942 the Children's Bureau and the Women's Bureau of the U. S. Department of Labor, in consultation with a group of representative industrial hygienists, women personnel directors and obstetricians, met and recommended certain standards for maternity care in industry;³ and shortly afterward the Committee on Health of Women in Industry of the Section on Obstetrics and Gynecology of the American Medical Association drafted similar recommendations.⁴ Both bodies agreed that, ideally, the pregnant woman should not be employed. But they were also unanimous in their belief that the employment of pregnant women in industrial plants was entirely feasible and safe, provided certain safeguards could be thrown about them. Among these safeguards were facilities for adequate antepartum care, avoidance of work on the night shift, rest periods, the avoidance of occupations which demand heavy lifting, continuous standing or a good sense of bodily balance and, finally, a minimum of six weeks' leave before delivery.

In whatever class of society, a sedentary, unoccupied life is not conducive to the health of the expectant mother. In World War I, when large numbers of pregnant women were employed in Great Britain in munition and other factories, medical witnesses agreed that light factory work was not prejudicial to the health of expectant mothers;⁵ moreover, in a study carried out by the Women's Industrial Council of that country on 934 women industrial workers the conclusion was reached that "there is practically nothing to choose in quality of maternity care between those who go out to work and those who stay at home."⁶ In the present war O'Sullivan and Bourne have made similar observations on a series of pregnant women in a factory doing specialized work in London and have reached similar conclusions.⁶

In view of the recommendations of the two American committees mentioned and in the light of the British experience with employed pregnant women in this and the last war, it might appear that the problem needs no further discussion since it seems to have been clearly established that it is just as safe, with certain reservations, for pregnant women to work in industrial plants as it is for them to work at home. Actually, in this country at least, the problem is far from solved for the very cogent reason that our industrial plants, in the main, will have nothing to do with pregnant women and summarily discharge them as soon as pregnancy is discovered. In a valuable recent survey of seventy industrial establishments, Charlotte Silverman² found that among the sixty-two firms which had established some kind of a maternity program the policy in 50 per cent was dismissal on notification or discovery of the pregnancy or during the first three months. The chief basis for this regulation is fear of the legal responsibility associated with the employment of pregnant women, especially the concern that the occurrence of abortion may be attributed to work done in the factory. As a matter of fact, in Silverman's entire survey she was able to learn of only 1 instance in which a worker charged

that abortion had occurred as the result of her employment.

From the point of view of the industrialist and the nation's manpower, this policy of excluding pregnant women from industrial plants eliminates from utilization a large number of willing, valuable and skillful workers. From the point of view of maternal welfare in this country it causes workers to conceal their pregnancies, whereby they forfeit the advantages of early antepartum medical attention; and, in not a few instances, it throws them into the hands of the criminal abortionist. Furthermore, it fosters an unwholesome attitude toward maternity and tends to make mandatory the use of contraceptive procedures, all at a time when our nation will be needing these babies.

This abuse of rest imposed on pregnant women by most industrial concerns is an unjust and unnecessary penalty for motherhood and stands in need of correction. As a step toward this end, Miss Caroline G. Olsen, R.N., has prepared a "Suggested Pregnancy Adjustment Plan for Women in Industry"⁷ which merits wide consideration by physicians and industrialists alike. Her program is a concrete and workable protective plan for the supervision of women in industry in such a form that industrial plants should be able to put it in force without serious difficulty. It is to be hoped that through this and other means industrialists may become aware of their responsibility in this important problem.

The second abuse of rest in obstetrics concerns itself with the purported necessity of 'several years' rest between pregnancies, if the best interests of mother and child are to be served. Based on an observation made by Woodbury⁸ in 1915 this teaching that babies are less likely to survive if born at intervals of less than two years has had wide circulation and has become both to the physician and to the public almost an axiom of maternity. It is responsible, more than any other doctrine, for the tendency to procrastinate childbearing and, in turn, this procrastination is responsible, more than any other factor perhaps, for the low birth rate among certain very desirable social and income groups. In a recent statistical study which has been reported in detail elsewhere,⁹ it has been shown that: 1. Infants born from twelve to twenty-four months after a previous viable delivery (that is, during the second year) have at least as low a stillbirth and neonatal mortality as do infants born after longer intervals. 2. The longer the interval between births, the more likely the mother is to suffer from some form of hypertensive toxemia of pregnancy. The incidence of this complication is lowest when the interval is twelve to twenty-four months, significantly higher when it is twenty-four to forty-eight months, and much higher when it exceeds four years. 3. In patients who have had a previous hypertensive toxemia of pregnancy, the likelihood of repetition becomes progressively greater as the interval becomes longer. 4. The incidence of premature labor, anemia, postpartum hemorrhage and puerperal infection is no greater when the interval is twelve to twenty-four months than when it is longer, nor are mothers in this brief interval group less able to nurse their babies. The weight of the mature babies was approximately the same regardless of the interval.

9. Eastman, N. J.: The Effect of the Interval Between Births on Maternal and Fetal Outlook, Am. J. Obst. & Gynec. 47:445, 1944.

These recent findings so contradict the old, deep rooted teaching that frequent childbearing is dangerous, as to make them seem on first consideration rather incredible. Yet they are based on two separate investigations, one covering over 5,000 cases and the other over 33,000, and their statistical validity is beyond question. Moreover, if they are considered in the light of maternal and fetal mortality rates according to the age of the mother they appear altogether logical and, indeed, are exactly what one would expect. Child spacing, by definition, means maternal aging; and after a certain optimum period, probably in the early twenties, maternal aging means inevitably somewhat higher risks both to mother and to child. All experience and all statistics support this statement. Whatever advantage is gained by a rest period of several years between births seems to be offset and in some respects more than counterbalanced by the aging factor. for it must never be forgotten that the most important talisman which a childbearing woman can possess is youth.

THE ABUSE OF REST AS A THERAPEUTIC MEASURE IN SURGERY

EARLY POSTOPERATIVE ACTIVITY AND REHABILITATION

JOHN H. POWERS, M.D.

COOPERSTOWN, N. Y.

Rest, as a therapeutic measure, is fraught with hazard. Prolonged periods of recumbency in bed are anatomically, physiologically and psychologically unsound and unscientific. Conversely, early restoration of medical and surgical patients to normal life is an essential feature of modern convalescent supervision. Prompt postoperative activity and walking provide manifest, safe and agreeable modifications in customary convalescent care by which ready rehabilitation may be achieved in the realm of surgery.

The desirability of such a program for patients of advanced years has long been recognized; surgical wounds heal firmly even though early postoperative activity is encouraged. Infants and young children cannot be kept quietly at rest in bed after operation, yet postoperative hernias are not common. Utilization of this knowledge in the management of patients between the extremes of life promotes an equally uneventful convalescence. Early rising from bed and walking preclude the protracted period of inertia which traditionally follows in the wake of surgery and encourage the prompt resumption of normal activity.¹

PRESENTATION OF DATA

My purpose in this report is to present observations on the postoperative convalescence of 100 consecutive patients who were allowed to sit in a chair and to walk on the first day after major operations, and to compare these studies with similar observations on an equal number of consecutive, unselected patients who remained in bed for the traditional period of ten to fifteen days after operations of the same type and magnitude.

For the sake of simplification the operative procedures have been limited to hernioplasty for inguinal, femoral, umbilical, epigastric and incisional hernias; appendectomy for acute appendicitis, including cases of perforation with abscess and peritonitis; cholecystectomy with and without exploration and drainage of the common duct, and hysterectomy and other major pelvic operations performed through an abdominal incision. The patients in both groups were all over 12 years of age.

The temperature and pulse rate during the postoperative convalescence, the number of days of confinement to bed, the length of time spent in the hospital and the total duration of the convalescent period have been chosen as criteria for comparison. The convalescence is considered as beginning with the first postoperative day and continuing until the patient resumed full activity at the work which was interrupted on entrance to the hospital for surgical treatment.

The comparative studies after each type of operation are presented graphically and in tabular form. The total cases are also discussed in their entirety.

1. *Hernioplasty*.—This group includes 39 patients who were up and walking on the first day after operation and an equal number who followed the traditional regimen of twelve days in bed after repair of a single rupture and fourteen or more after bilateral or ventral hernioplasty.

Presented in chart 1 are curves representing rectal temperatures and pulse rates before and during the first ten days after operation. These were plotted by averaging the highest levels recorded for every patient in each category on each day. They thus represent maximal elevations during the convalescent period. No significant variations are apparent in either the temperature or the pulse rate of the early and late patients.

The types of hernias, the average and extreme ages of the patients, the number of days in the hospital and the total weeks of convalescence are also tabulated in chart 1. Those patients who were permitted early activity spent an average of 9.1 days in the hospital and required 5.6 weeks for convalescence. Seven of these hernias were complicated by incarceration or strangulation of the omentum or intestine. The patients in the control series averaged 15.2 days in the hospital and did not return to work until ten weeks after operation. Incarceration or strangulation was a complicating factor in 5 cases.

All but 3 patients have been reexamined in the follow-up clinic at varying intervals. No recurrences have developed among those who were up on the first postoperative day; 1 inguinal and 1 femoral hernia recurred among the patients who remained recumbent for twelve days or more.

2. *Appendectomy*.—The diagnosis of acute appendicitis in all cases was supported by microscopic examination of the appendix. Among the 22 patients who were allowed out of bed on the first postoperative

day were 1 abscess and 4 cases of local peritonitis; among the same number of controls were 5 cases of peritonitis of comparable severity; all were confirmed by positive bacteriologic cultures.

McBurney and right rectus incisions with and without drainage were used in both groups (chart 2).

days after operation. All 3 ruptures were located at the medial angle of oblique subcostal incisions.

The mean temperature and pulse rate of the patients who were up on the first postoperative day were significantly lower than were those of the patients who remained in bed. Their convalescence in the hospital was materially shortened and their total average period of rehabilitation was reduced one half by early postoperative activity (chart 3).

4. *Abdominopelvic Surgery*.—In this group are 25 patients who were up and walking on the first postoperative day and an equal number who remained in bed for an average of 13.4 days. The lesions and abnormalities which required operative therapy are tabulated in chart 4. Supravaginal or panhysterectomy was performed ten times in the former group and eight times in the latter; salpingectomy, oophorectomy or salpingo-oophorectomy without removal of the uterus, twelve times in the early group and eight times in the late. Only 1 patient was allowed up on the first day after repair of a cystocele, rectocele and prolapse.

The average age of the patients in the early and control series was almost exactly the same. The length of time spent in the hospital after operation and the total period of convalescence for the patients who were allowed early activity were 11.7 days and 6.7 weeks respectively; for those whose regimen followed the former temporal pattern, the averages were 16.7 days and 11.6 weeks.

Chart 1.—Clinical and additional data relative to 39 patients who were out of bed and walking on the first postoperative day after hernioplasties, compared with an equal number who remained recumbent for thirteen days.

The postoperative convalescence of those patients who were allowed to sit in a chair and to walk on the first postoperative day was uncomplicated. Their mean temperature and pulse rate were consistently lower than were the temperature and pulse of those who remained in bed for an average period of 9.8 days (chart 2). Postoperative residual intraperitoneal abscesses developed in 2 of the latter group; there were none among the patients who were ambulatory early.

It is significant that the patients who were activated promptly returned to work in 4.8 weeks, while those who remained in bed for the customary convalescent period did not resume their usual occupation until 8.7 weeks after operation.

3. *Cholecystectomy; Choledochostomy*.—Fourteen patients were ambulatory on the first day after operations on the biliary tract; compared with these is an equal number who remained in bed for an average period of 15.3 days. Cholecystectomy was performed through an oblique subcostal incision six times in the former group and five times in the latter; through a vertical right rectus incision twice in the first and four times in the second group. All wounds were drained with a cigaret wick down to the foramen of Winslow. In addition to cholecystectomy, the common duct was explored and drained six times in the ambulatory group and five times in the control series. Four of the former were visibly jaundiced at the time of operation; all wounds healed firmly. One patient who was not icteric developed a late incisional hernia subsequent to discharge from the hospital. Two such hernias occurred in patients who remained in bed sixteen and twenty

Chart 2.—Clinical and additional data relative to early and late activity during convalescence from appendectomy for acute appendicitis.

Composite graphs of the temperature and pulse rate are presented in chart 4.

5. *Total Cases*.—All operations were of major magnitude; many were performed as emergencies; others were necessitated by the presence of mechanical abnor-

malities, acute or chronic inflammatory lesions, tuberculosis or neoplasm.

The mean age of the total group of 100 patients who were permitted to sit in a chair and to walk on the first day after operation was 43.4 years. The age of an equal number of control patients was 38.7 years; this group

Chart 3.—Data relative to early and late activity following cholecystectomy and choledochostomy.

averaged 12.7 postoperative days in bed. The ambulatory patients spent 10.3 days in the hospital, while those who followed the traditional convalescent program averaged 16.1 days (chart 5). This represents a saving of 580 hospital bed-days. In a locality where many of the patients live close at hand, this economy of beds may be greatly augmented by even earlier discharge from the hospital. Cutaneous sutures may be removed at home or in the outpatient department. Such an individual is well able to travel short distances by automobile on the third or fourth postoperative day. In rural areas, where transportation is a problem, such premature dismissal is not feasible.

The average period of convalescence after early activity was 5.7 weeks; after traditional postoperative management, 10.3 weeks. These figures indicate that, by the elimination of deconditioning secondary to a period of ten to fifteen days of recumbency following major surgery, the patient may return with comfort and safety to his usual occupation four and one-half weeks earlier than has been customary when traditional routine is followed.

If the temperature and pulse rate are regarded as accurate indexes of convalescence, such early activity is in no way deleterious (chart 5). However, other

postoperative complications may arise which are not reflected in the clinical chart.

6. Postoperative Complications.—Postoperative complications may be classified as local (those which involve the wound and adjacent tissues), pulmonary, cardiac, vascular, genitourinary, gastrointestinal and general. Following this classification, the incidence of complications which were observed in these two unselected groups of 100 cases each is given in table 2.

No local complications of major significance occurred because of early activity. No wounds disrupted. One incisional hernia developed several months after operation, an incidence of 1 per cent. One infection was strictly an operative mishap. The 2 hematomas were of minor importance but may conceivably be attributed to early ambulation. Two incisional hernias, 2 recurrent hernias, 1 hematoma and 1 silk sinus occurred among the patients who were kept recumbent for the customary postoperative periods.

Serious pulmonary complications were likewise more common among the patients who remained in bed (table 2).

No cardiac complications were observed among the ambulatory patients. In this group were 8 persons between 70 and 80 years of age and 2 who were over 80 years old.

The incidence of vascular complications was reduced but not eliminated. This phase of the subject is discussed in some detail later.

Postoperative inhibition of the bladder was rather common in both groups. It is of significance, however,

Chart 4.—Data relative to early and late activity after pelvic surgery through an abdominal incision.

that in the ambulatory group the difficulty in voiding usually occurred during the night of the day of operation. Only 2 patients required subsequent catheterizations after they were up and about. Repeated catheterizations were much more frequent among the patients whose convalescence was spent in bed.

Postoperative dilatation of the stomach and fecal impactions occurred only in this group.

Fever which could not be explained by reaction to operation or to the disease for which operation was performed was observed in 5 patients among the recumbent group.

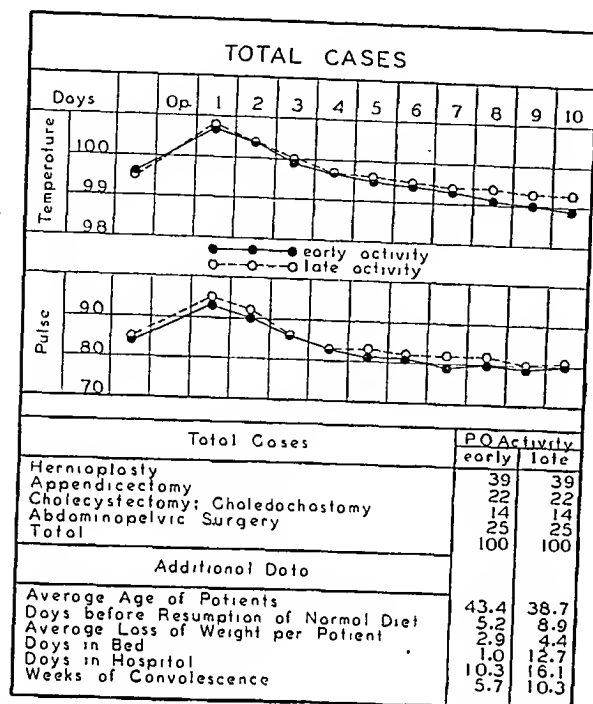

Chart 5.—Composite clinical records and summary of additional data relative to all patients who were up and walking on the first day after major surgery compared with an equal number who remained recumbent for 12.7 days after operations of similar scope; 100 patients in each group.

In total there were 17 postoperative complications among the hundred patients who were out of bed on the first day and 46 among the same number in the unselected control group.

6. *Sutures*.—Accurate reapproximation of tissues is compulsory, if early activity is planned, preferably with nonabsorbable, interrupted sutures except in the peritoneum, which may be closed with a continuous stitch. Additional supporting sutures of silkworm gut or silver wire may be desirable for obese patients and in the presence of infection. Silk was employed most frequently in the cases herewith reported (table 1). Catgut alone was not used sufficiently often to be certain of its integrity without reinforcement by stay sutures of nonabsorbable character. However, proper and accurate coaptation of tissues, meticulous hemostasis, assiduous care in the prevention of infection, and gentle manipulation of tissues are undoubtedly of more importance than the nature of the material with which the wound is sutured.

COMMENT

1. *Physiologic Considerations*.—(a) *Pulmonary*: Elevation of the diaphragm in recumbent position, pooling of tracheobronchial secretions in the finer ramifications of the bronchial tree, the patient's disinclination to cough because of pain, the limitation of maximal respiratory excursions and invariable reduction in vital capacity after laparotomy or hernioplasty² all play some

role in the etiology of postoperative atelectasis and pneumonia. The volume of tidal air, tension of oxygen in the alveolar spaces, oxygen saturation of arterial blood, and the depth and rate of respiratory movements are increased by exercise. Hence early postoperative walking may reasonably be of definite therapeutic value in the prevention of pulmonary complications. Some authors believe that the incidence of such complications is reduced 75 to 80 per cent by prompt ambulation.³

(b) *Circulatory*: The circulation time from the ankle to the carotid sinus is decreased by elevation of the extremity and by active exercise of the leg with the

2. Powers, J. H.: Vital Capacity: Its Significance in Relation to Postoperative Pulmonary Complications, *Arch. Surg.* 17: 394-323 (Aug.) 1928.

logic factor which presumably may be directly and favorably influenced by early activity and walking. Methods to decrease venous stasis and the incidence of thrombosis by position and exercises in bed have not been universally successful. Actual walking, however, is said by many authors to minimize the development of thrombosis.³

The occurrence of 1 case of ileofemoral thrombophlebitis and 1 of suspected thrombosis in the deep veins of the leg among the ambulatory patients (table 1) indicates that early postoperative walking does not entirely circumvent the formation of thrombi; it may, however, obviate the liberation of emboli of sufficient size to precipitate a fatal postoperative catastrophe. A thrombus of this magnitude does not usually develop in an active venous circulation.

(c) *Gastrointestinal:* Postoperative dysfunction of the gastrointestinal tract is uncommon when early convalescent activity is permitted. Abdominal distention is rare. Enemas, rectal tubes and poultices are seldom necessary. On the fourth or fifth postoperative day a regular diet may be accepted with neither distaste nor discomfort (chart 5).

(d) *Musculoskeletal:* The absence of asthenia has impressed all observers who have advocated early ambulation after surgical operations and after rigid fixation of fractures. Demineralization of bones and atrophy of muscles, so common after prolonged periods of rest in bed, are entirely obviated. The convalescent period of reconditioning before return to normal activity is reduced to approximately one-half its former magnitude (charts 1, 2, 3, 4 and 5).

(e) *Reparative:* The attitude of the majority of surgeons toward the healing of wounds is one of conservatism, based in no small part on the teachings of Billroth, who believed that rest and protection were essential for proper repair of coapted tissues. Contrary to this orthodox opinion, those who have advocated early postoperative walking have observed no deleterious effect as a result thereof, no increase in pain, no greater frequency of disruption or hernia. Some authors claim an even kindlier and more rapid healing when patients are allowed to be up and about during the early postoperative convalescence.⁵

2. *Psychologic Aspects.*—The improvement in morale is striking. From previous experience, or from the tales of relatives or friends, many patients anticipate surgical operations with fear and apprehension. "Gas pains," bed pans, enemas and hypodermics are foreseen with horror. When such a patient learns that he is to get out of bed and walk on the first or second postoperative day, he is permitted the freedom of the ward on the third or fourth, and lead an essentially normal life shortly thereafter, his whole attitude toward the operation and his hospital experience undergoes a profound change. The fear of surgery and the discomforts of the convalescence may be largely eliminated by a program of accelerated activity.

3. *Economic Factors.*—Postoperative care is tremendously simplified. Within a few days patients are able to attend to their own requirements and also assist with a few simple duties in the ward. The services of a limited number of graduate nurses are thereby made more readily available for the essential treatment of patients who require professional attention.

Early discharge from the hospital effects an economy for the patient and an efficient utilization of beds by the institution.

Prompt rehabilitation insures a minimal loss of time from work and the early reestablishment of normal activity.

CONCLUSION

Prompt restoration of surgical patients to normal life is an essential feature of convalescent supervision. Early postoperative activity and walking provide manifest modifications in customary convalescent care by which the process of reconditioning may be largely eliminated and early rehabilitation achieved.

The indications for such a program are manifold; no contraindications are apparent in this study of 100 consecutive cases.

THE EVIL SEQUELAE OF COMPLETE BED REST

WILLIAM DOCK, M.D.

LOS ANGELES

It is rarely possible to ascribe to bed rest alone the disorders which become manifest in patients confined to bed during the treatment of disease or injury. Inter-current illnesses sometimes develop in spite of bed rest, as when myocardial infarction occurs during convalescence from a pelvic or orthopedic operation. In most cases the evil effects of complete bed rest are potentiated by anesthesia, narcotics or other medication or by the results of the original illness. But it must also be recognized that many disturbances of function, such as massive collapse of the lung, attributed to operation, illness, anesthesia or medication have become evident only because the patient was forced to spend hours or days in the dorsal recumbent position.

In any discussion of the effects of complete bed rest it is to be borne in mind that the disorders noted may have been aggravated, or even initiated, by a depression of activity and responsiveness due to psychic trauma, anesthesia or sedation. Even prolonged bed rest is rarely followed by serious physical sequelae when lively young patients are kept in bed without any sedatives, whereas rapid onset of fatal complications most commonly occurs when indolent obese elderly patients are confined to bed after prolonged anesthesia, and with enough pain to justify continued use of sedatives and narcotics.

The effects of hospital life and of bed rest on the psyche are so obvious and have been so clearly described by such novelists as Tolstoi and Balzac that most laymen are well aware of this hazard of therapy. At the present time the effects of complete bed rest on metabolism and on the structure and function of healthy volunteers are being subjected to a careful quantitative study. Bone atrophy,¹ muscular wasting² and vasomotor instability are not infrequent sequelae of bed rest, while constipation, cathartic habituation, backache and many other chronic disabilities may appear during bed

From the University of Southern California Department of Medicine. Read in a symposium on "The Abuse of Rest in the Treatment of Disease," before the Section on Experimental Medicine and Therapeutics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

rest and persist for years or decades. The onset of obstructive uropathy or of pulmonary edema on confining elderly patients to bed are phenomena which interns in large city hospitals observe only too often. Nothing more will be said here of these serious complications or of the classic lesion due to bed rest—pressure necrosis or bed sore.

Other vertebrates, and notably the birds, share man's bipedal erect posture, but so far as I know no other animal lies on its back when ill. Indeed, it is almost impossible to conduct experimental studies of the effects of the dorsal recumbent posture, maintained for days or weeks, in any species but man. Normal sleep is associated with frequent changes from supine to prone or lateral positions, and this restless type of activity is usual also during the sleep of many patients confined to bed but not in shock, pain or prostration.

During his waking hours the patient treated by complete bed rest lies on his back, and he sleeps, or tries to sleep, in that position after operations or when kept in the orthopedic or Fowler posture. Since this is not a restful way to sleep, sedatives are given to many patients who are required to live in this fashion. Thus the stage is set for many hours of inert recumbency, with shallow breathing and diminished muscle tone. The serious evil sequelae of complete bed rest may appear in a few days; a few phlegmatic or profoundly depressed patients may exhibit these disorders without receiving any narcotic or sedative.

The total metabolism and the muscle tone are obviously low in the type of patient just described. This decreases the volume of flow in all the vessels of the body, but if the patient lies flat at all times the venous pressure is low and the caliber of the veins small. In the abdomen, pelvis and legs the veins then are much smaller than when sitting up, as one can readily see if the veins of the back of the hand are observed when recumbent, with the hands at the level of the great trochanter, and when sitting up with the hands resting on the thighs. With the veins at this small caliber the velocity of blood flow will be high in spite of the decrease in volume of flow, but when the shoulders are propped up the veins of the pelvis and legs are dilated and the velocity of flow correspondingly reduced, possibly to one-tenth that when the veins are in the same plane as the heart. Frykholm³ felt that collapsed veins might have endothelial damage, predisposing to later thrombosis, but the fact is that the veins on the anterior aspect of the legs, which obviously are under least venous pressure, almost never become thrombosed during bed rest. Veins compressed and empty, due to pressure of the leg against the bed, may easily suffer endothelial damage and begin to thrombose while still nearly empty. Only when sitting or standing are these veins constantly dilated to their full caliber, but during paroxysms of coughing, or when bearing down to facilitate expulsion of flatus, feces or urine, transient maximal venous dilatation may occur even when one is lying perfectly flat. The formation of large clots propagated far along the system is made possible by the prolonged absence of sighing respiration, cough or bearing down and by the constant elevation of the heart above the pelvis. Dislodgment of clots, with formation of emboli, is effected when there is a sudden rise of venous pressure. As the wave of pressure and venous distention sweeps outward along the venous system, loosely adherent clots, formed in collapsed or partly dilated veins, are stripped away from the wall. If

episodes of venous dilatation are frequent, propagation of clots is almost impossible, as the thrombi are dislodged from the minute vessels in which clot formation begins. Such small thrombi are well tolerated by the lungs, and most of them probably dissolve before organization begins. Patients who get up several times a day and those with severe cough, with acidosis, uremia, anemia or impaired blood coagulation therefore are much less subject to serious vascular accidents during bed rest, either because clots form and grow less readily or because they are dislodged before becoming of significant size. The greatest hazard is in those who are propped up slightly for eight to fourteen hours a day, as this favors clotting in partially distended veins.

It is now believed that phlebothrombosis rarely begins in the large veins but in the venules of the muscles and subcutis or in the pelvic venous plexuses where complete stasis is possible.⁴ Thrombosis in the feet, calves and thighs begins in the dependent parts, where prolonged pressure and ischemia cause tissue damage.⁵ Such lesions may be thought of as the internal equivalent of bed sores, but unfortunately they are far more frequent. Among middle aged and elderly patients, dying after days or weeks of bed rest, thrombosis in veins of the dorsal part of the legs and feet were demonstrable in one fourth to one half of the cases in large series studied in Germany, in Sweden and in Oregon.⁶ Fatal pulmonary emboli were present in about 4 per cent of the cases with thrombi in the legs, and nonfatal emboli in about 20 per cent more.⁷

Consideration of the effect of bed rest on the systemic veins ends with the embolization of the pulmonary arterial system, but discussion of the results of embolization calls for a review of the effect of the supine posture on the lungs. The occurrence of acute massive collapse, in postoperative cases especially, is well recognized and much is known of the mechanism and prevention of this type of disorder.⁸ The pathologist has known for years that patients dying after only a day or two in bed may have airless patches scattered through the dorsal and caudal parts of the lungs. In the lungs, as in the skin, postmortem lividity due to settling of blood makes the dorsal parts of the lungs very bloody, so the pathologist can tell little or nothing of the passive hyperemia present in these regions during life. But physical signs and roentgen studies do indicate the occurrence of hyperemia and edema in the dependent parts of the lungs, especially on the right side, in many patients who spend most of their time in the dorsal and right lateral decubital positions. Such hyperemia and edema probably predisposes to collapse of the local regions. While it is not likely that collapse occurs post mortem, it must develop rather rapidly during the agonal state as respiration fails and accumulation of fluid in large bronchi interferes with aeration. Patients with air hunger and deep respiration up to the final hour show notably less collapse post mortem than do those with normal blood levels of hemoglobin and base, and radiologists are familiar with the clear peripheral lung fields and hilar hyperemia in cases of

combined heart failure and uremia.⁹ This so-called "pulmonary azotemia" actually should be called "pulmonary hyperemia with acidosis," for it is the acidosis and air hunger which prevent the collapse of many alveoli so common in bedfast patients with dorsal passive hyperemia or with the pulmonary hyperemia of heart failure. It is in these collapsed parts that terminal, or hypostatic, pneumonia develops, and here is where necrosis begins whenever pulmonary infarction follows pulmonary embolism. In the aerated lung, pulmonary embolism raises the oxygen tension by diminishing the inflow of reduced blood from the right ventricle, and even if the bronchus is closed as well as the artery the tidal movement of oxygenated blood in the pulmonary vein maintains the viability of the tissue as long as the pulmonary veins dilate and collapse during the cardiac cycle. In dependent parts of the lungs the veins are fully distended throughout the cardiac cycle and tidal flow ceases.

It was formerly taught that infarcts occur only in patients with passive hyperemia of the lungs, but now it is known that they follow pulmonary embolism in 60 per cent of surgical and medical cases without heart failure and in 90 per cent of the cardiac.¹⁰ Here again the combination of dorsal decubitus with sedatives which depress respiration serves to pave the way for trouble, and young men previously in excellent health may have pulmonary infarction within a week of an otherwise uncomplicated laparotomy or herniorrhaphy if they have been kept "comfortable and quiet" by skillful nursing and constant medication. In not a few cases the infarct develops, not at the time of embolization, but some days later when collapse happens to occur.¹¹

A discussion of the hazards of bed rest would be incomplete without emphasizing the tremendous strain put on the heart and circulation by a maneuver which patients in bed frequently perform and against which many are never warned. Whenever one takes a deep breath, closes the glottis and tightens the thoracic and abdominal muscles (Valsalva's experiment, "bearing down") there follow a series of extreme fluctuations in thoracic pressure, cardiac output, blood pressure and vagal and vasomotor tone. After myocardial infarction sudden death is far more likely to occur when the patient performs this effort than from any other cause, and it is a common incitant of pulmonary embolism. This may occur on the bed pan or even when passing flatus or trying to push oneself higher on the pillows. Patients with difficulty in urination or defecation probably undergo less risk if warned against this procedure and allowed to get out of bed to use a commode than when left to struggle in a supine position. To put a man at complete rest for heart disease without making sure that the Valsalva experiment is never carried out, at any time, is about as illogical as forbidding a patient to do desk work but letting him run upstairs. Every physician should be acutely aware of the fact that simply ordering "complete bed rest" does not protect the patient from severe periodic stress on the heart and circulation, while it does expose him to definite danger.

At another occasion it might be profitable to review the therapeutic measures necessary to minimize the

hazards of complete bed rest. Obviously these will include omission or rigid restriction of narcotics and sedatives, encouragement of deep breathing exercises, frequent changes of posture and acceleration of venous flow in the legs by elevating the foot of the bed and not the patient's thorax, or by exercise or reactive hyperemia from brief arterial compression. There is no doubt that precautions based on an understanding of phlebothrombosis,¹² pulmonary embolism and infarction¹³ will greatly reduce the evil sequelae of complete bed rest in those cases in which it seems necessary in spite of its hazards. But this still leaves the inevitable residue of tragic cases in which bed rest is the chief agent of disaster. The physician must always consider complete bed rest as a highly unphysiologic and definitely hazardous form of therapy, to be ordered only for specific indications and discontinued as early as possible.

THE ABUSE OF REST IN BED IN ORTHOPEDIC SURGERY

RALPH K. GHORMLEY, M.D.

ROCHESTER, MINN.

Among orthopedic surgeons the importance of rest as a therapeutic measure has been emphasized since the beginning of this specialty. It is generally recognized that Hugh Owen Thomas was one of the forerunners of orthopedic surgery. In his book "Menders of the Maimed" Sir Arthur Keith said "It was the custom of John Hunter to prescribe 'Rest' as a routine measure in the treatment of disablements of the motor system of the human body. After him came John Hilton, who regarded rest as the most powerful aid which the surgeon could bring to the aid of disordered tissues. Hilton elaborated the means of securing rest into a system; but the man whose principles and practice we are to describe here made rest his creed and ritual. Hugh Owen Thomas believed that an overdose of rest was impossible. To use the expression which he never tired of repeating—Rest must be 'enforced, uninterrupted and prolonged.'"

Thus one may see that the creed prescribed for orthopedic surgeons of a generation or more ago called for rest in considerable quantities. This may have been and probably was carried to an extreme beyond reason. However, one must consider that many of the patients for whom this treatment was employed had tuberculous infection of bone, and while other means of eradicating tuberculosis have brought about a striking decrease in the incidence of the disease, particularly in the number of cases of tuberculosis of bones and joints,

rest still remains the best known means of combating that disease in the human body. For many years the only form of treatment consisted of years of rest in bed in the patient's home or in a hospital. Splinting of joints, supporting dietary regimens, heliotherapy and other things were supposed to add to the efficacy of the treatment, but the main feature was rest.

For the past thirty years the fact that more perfect rest to diseased joints could be brought about by internal fixation of the spinal column and major joints by means of operative fixation with bone grafts or by a fusion operation has come to be recognized. Now tuberculous joints, when recognized, usually are treated in this manner and a decrease in the period of rest in bed and hospitalization, and for the most part improvement in the results has been effected. Severe kyphosis is rarely seen, and the extreme destruction of joints with pathologic dislocation is not often seen. In addition, the bad effects of long rest in bed have been reduced.

Elsewhere in this symposium the deleterious effects of long rest in bed will be considered. From the standpoint of the orthopedic surgeon, one effect deserves emphasis perhaps beyond that which it will be given by other speakers. This effect is atrophy. Atrophy of muscles, articular structures, bone and skin results from prolonged rest and must be regarded as a pathologic condition. The actual pathologic physiology of this condition is not well understood. Certainly there are other factors than simple disuse that contribute much to certain types of atrophy, but the effect of disuse alone is sufficient to lead to a good deal of disability. If one opens a thigh to remove fascia for surgical procedures one will be struck by the smooth surfaces of contact between the fascia and underlying muscle. These surfaces fairly glisten and are not adherent; obviously, smooth, gliding movements between the muscle and fascia are not impeded. On the other hand, when one opens a thigh that has been at rest either in a cast or in a splint or as a result of rest in bed one often finds that the fascial surface as well as the surface of the underlying muscle is dull and does not glide; oftentimes many small adhesions have formed between the muscle and the fascia. This seems mainly the result of disuse and inactivity or, in other words, an alteration from the normal physiology of the involved region. I often have thought that, if such changes take place between all muscles and their fascial coverings or gliding envelopes, they must have a considerable effect in producing limitation of function in the skeletal system. To a lesser extent and to a less pronounced degree the same effects, as a rule, may be seen in joints which are not used and in cases in which rest in bed is employed; however, bony atrophy may become symptomatic and even progress to the point where pathologic fractures may take place. A similar condition may take place in the skin, and the dangers of decubitus ulcers in bedridden patients are well known. Much of this atrophy can be avoided by systematic massage and exercises in cases in which, for some reason or another, it is necessary to remain in bed for a long time. Too often, however, such measures are overlooked, forgotten or neglected to the certain detriment of the patient.

One of the most common and most severe effects of rest in bed is embolism; however, this does not occur frequently in orthopedic cases. Most orthopedic patients are turned frequently enough when in bed to prevent this catastrophe, and the surgeon who neglects to see that his patients are turned over at least two or three times daily may find this complication arising more often than it should.

The main group of cases in which orthopedic surgeons have to employ rest in bed as a part of the treatment are cases of disease or injury of the spinal column, pelvis, hip or femur. There is scarcely any form of disease or injury of these parts in which efforts to reduce the period of rest in bed have not produced good results. The period of rest in bed in such cases, therefore, has been greatly reduced.

FRACTURES OF THE FEMUR

Fractures of the Neck of the Femur.—One of the outstanding examples of such reduction is in the treatment of fractures of the neck of the femur as well as intertrochanteric fractures of the femur. The method of treatment which formerly was used universally included putting the patients in bed and employing Buck's extension or applying a weight to the injured leg. Whitman's¹ method of reduction and application of a cast reduced the period of enforced rest in bed to some extent and did much to improve the results of treatment of fractures of the neck of the femur.

In 1931 Smith-Petersen² introduced the method of fixation of fractures of the neck of the femur by means of a three flanged nail. This method soon came into widespread use, and although many types of instruments for internal fixation have been devised and many methods of introducing the fixatives have been developed, the principle of internal fixation of such fractures has undoubtedly come to stay and with it a definite shortening of the period of rest in bed. Not all surgeons are in agreement as to the length of time necessary for convalescence in cases of this type of fracture. Soon after the method was introduced, many surgeons advocated that the patients be gotten up immediately after the operation and that ambulatory treatment be commenced. It is my impression from my own experience and from the observation of other surgeons that most surgeons prefer to keep the patient in bed for three to five weeks after such fixation. This is, of course, a great reduction in the period of rest in bed formerly employed, and it has produced great improvement in the results obtained, from the standpoint both of the percentage of united fractures and of the great decrease in the number of complications arising during convalescence.

The quality of results obtained in the treatment of fractures of the intracapsular type has led to a widespread effort on the part of surgeons to improve the results and reduce the complications in cases of intertrochanteric fractures of the femur. Although this type of fracture seldom leads to nonunion and, for this reason, does not cause permanent crippling in as many cases as does intracapsular fracture, the incidence of complications, often fatal and largely due to the prolonged rest in bed incidental to the convalescence, is equally high. Although it cannot be said that the various methods of internal fixation of this type of fracture have as yet been as widely accepted or as well perfected as have those employed in cases of intracapsular fracture, it is my opinion that the general principle of early internal fixation of intertrochanteric fractures must be accepted and is here to stay. With it will come a shortening of the period of rest in bed and a consequent improvement in the general well-being of the patient.

Surg.* 36: 746-761, 1902; The Abduction Treatment of Fracture of the Neck of the Femur: A Comparative Analysis from the Standpoint of Technical Efficiency, *Surg., Gynec. & Obst.* 27: 578-585 (Dec.) 1918.
2. Smith-Petersen, M. N.; Caves, E. L., and Vangorder, G. W. Intracapsular Fractures of the Neck of the Femur: Treatment by Internal Fixation, *Arch. Surg.* 23: 715-759 (Nov.) 1931.

Other Fractures of the Femur.—Other fractures of the femur often demand a period of rest in bed. Depending on the type of fracture and the type of treatment used, this period may last for several days to many months. Although traction methods are of value in many cases, it must be recognized that they necessarily prolong the period of rest in bed. In choosing a method of treatment, this factor must be taken into account. Indeed, in many instances open reduction for internal fixation and the subsequent application of a spica cast in order that the patient may be turned and even gotten up so as to avoid the deleterious effects of continued rest in bed in a supine position, such as is necessary when most traction methods are employed, will tend to cause less strain on the general condition of the patient.

In late years, many efforts have been made by various methods of pin fixation to get patients with a fractured femur ambulatory at an earlier date. Such methods as those of Roger Anderson,³ Stader and Haynes all point toward this.⁴

Although I do not want it to be construed that I advocate these methods of treatment of fracture of the femur, I do wish to emphasize that many surgeons are attempting, by using these methods, to have their patients walk early. All realize the dangers of long periods of rest in bed, and the effort of all forward looking surgeons is to shorten this period. Any method that has as its main advantage earlier ambulatory treatment will have a ready and wider hearing, and one must expect constant improvement of methods to this end.

LESIONS OF THE SPINAL COLUMN

An equally important group of lesions to be considered from this standpoint are fractures of the spinal column. Although patients with fractures of vertebrae accompanied by paraplegia are, of necessity, required to remain bedfast for a long time, it must be recognized that in this group of cases complications arise frequently, are difficult to control and often are fatal. Many of these complications are directly due to enforced rest in bed. Some effective means of treating this group of patients so that they may be allowed out of bed earlier would be most welcome. For the treatment of simple compression fractures and fractures without paraplegia there are available methods of reduction and control which will greatly shorten the period of rest in bed, which is desirable. Rest in bed for four to six weeks is adequate in practically all cases, provided adequate fixation of the spinal column with plaster is employed after reduction by means of a hyperextension frame or by hyperextension manipulation under anesthesia. For elderly persons with a compression fracture of moderate severity it has been our custom at the Mayo Clinic for several years to fit them with an adequate spinal support and get them up within a few days in order to avoid the almost inevitable complications that arise because of prolonged and continuous rest in bed.

The period of convalescence has been shortened after operations for fusion of the spinal column, particularly after fusion of the lumbosacral vertebrae for such conditions as spondylolisthesis, traumatic lumbosacral arthritis, spondylolysis and after fusion that is done at the same time as an operation for protrusion of an

intervertebral disk. Formerly it was not uncommon for patients to be kept in bed, and sometimes in casts, for twelve weeks after such an operation. Now, many of our patients are allowed to be up and about for a short period daily at the end of three weeks after operation. We often permit these patients to turn themselves from side to side and even to turn on the face three days after the operation. No ill results have been noticed from this change of procedure. Indeed, it seems that the patients have an easier convalescence and are able to resume activity with greater ease and comfort than they did formerly, when the period of rest in bed was two to four times as long as it is at present and when the rules as to the patients' turning themselves in bed were more strict.

ARTHRITIS

It is, of course, necessary to use rest in bed in the treatment of arthritis; but I have often thought that the day an arthritic patient gives up and goes to bed is the day he becomes a total cripple. I have been astonished at times to see patients obviously suffering from severe and disabling arthritis who, by sheer force of circumstances, have been prevented from giving up and going to bed. Such patients usually come through their ordeal with much better joints than do those who have been put to bed, even though the rest in bed may be accompanied by the best available treatment.

COMMENT

I have tried to point out that orthopedic surgeons, realizing the detrimental effects of complete rest in bed, have over the years succeeded in shortening the periods of such confinement in their prescribed treatment for various conditions. Efforts to improve treatment toward this goal continue, and one will see more advances along this line in the future.

THE ABUSE OF REST IN PSYCHIATRY

KARL MENNINGER, M.D.

TOPEKA, KAN.

A little over a hundred years ago a man was born in Philadelphia who became preeminent in three fields. In 1881 he was described by Sir James Paget as "one of the most distinguished medical men in your country or in any country." In addition to conducting one of the largest private practices in America, he was the author of a book of poetry, one of children's stories, numerous novels, a treatise on neurologic injuries and 250 articles on pharmacology, physiology, toxicology and psychotherapy. He received honorary degrees from Bologna, Edinburgh, Toronto, Harvard, Princeton and Jefferson. It is significant that a man of such prodigious labors and accomplishments should have made famous a program of treatment by rest!

Weir Mitchell described his "rest cure" in a number of books, the titles of which indicate his philosophy: *Wear and Tear*, *Hints for the Overworked*, *Fat and Blood*. His idea was that nervous illnesses were the result of physical exhaustion, which he combated by complete bed rest, complete isolation, no visitors, no letters, no reading, no writing; the constant attendance of a nurse, some massage and electricity and, withal, high caloric feeding.

From the Menninger Clinic.

Read in a symposium on "The Abuse of Rest in the Treatment of Disease" before the Section on Experimental Medicine and Therapeutics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

Mitchell's prestige, influence and persuasiveness were such that his "rest cure" for the treatment of neuroses influenced American medicine for nearly fifty years. The fact that persons with nonorganic illnesses who complained of "nervousness" seem to be wasting energy by unnecessary tensions, anxieties and fruitless exertions and that they suffer, subjectively at least, from a high degree of fatigability could not but impress physicians who, because they had been reared and trained in a mechanistic physiologic philosophy of human life, saw these cases without benefit of psychologic insight. The fatigue theory of the neuroses which so impressed Weir Mitchell thus continued to impress nonpsychologically minded physicians, who welcomed a plausible physiologic expansion of these baffling cases. Diagnoses of nervous exhaustion, nervous fatigue, fatigue neuroses, nervous breakdown from overwork, nervous weakness, neurasthenia and so on continued to fill the records of hospitals, clinics and private practitioners. Treatment based on these diagnoses and Weir Mitchell's example were developed, exploited and popularized—modified rest cures, relaxation treatment, vacation treatment and what I have called "trip treatment"—the sending of patients away on visits to California, Florida and Europe, or on fishing trips, hunting expeditions and the like.

Modern psychiatry regards this conception of neurosis and these forms of treatment for neuroses as entirely false in theory and unsound in practice. To relate ourselves again to the title of this symposium I will put it this way: the abuse of rest as a treatment in psychiatric conditions represents a neglect or misunderstanding of the real pathologic condition of the neurotic patient under the guise of a treatment which is not only futile and expensive but very often definitely harmful.

In the brief limits of time available it would be difficult to answer all the questions to which this statement will give rise. In a very condensed form I shall try to outline the modern theory of the neuroses and of the treatments considered appropriate for them in contrast to those which justify the practice of prescribing excessive rest and indicate, in closing, some of the ways in which rest can be used without abuse.

There is no question but that nervous patients show evidences of fatigue and easy fatigability; this fatigue is a symptom of the neurosis. Overstudy, overapplication, overexertion and all other excess expenditures of energy do not cause psychiatric syndromes; they are often the expression of psychiatric illness. The cure of the psychiatric illness—the neurosis, the nervousness—is the removal of that which impels the individual to make such depletions of his own strength, to waste so much of his energy or to require so much of it to hold himself in check against explosions or collapse. The modern conception of a psychiatric illness is a dynamic one based on a concept of cooperative and interactive anatomy, physiology and psychology. The neuroses and psychoses and other evidence of maladjustment on the part of a patient are a result of misdirected energy rather than the lack of sufficient energy. An automobile the engine of which has become overheated as the result of being driven with the brakes set cannot be cured by resting. As soon as the car's proper function, that of traveling along the road, is resumed (with the brake still set) the same overheating will result. The

question is Why are the brakes set and how does one release them?

The problem of treatment of a psychiatric illness thus goes beyond merely arresting any attempt at adjustment by physical exertion. It aims at the redirection of the wasted energy, the removal of interfering inhibitions and the setting up of requisite inhibitions. Human beings are impelled by instinctual forces to attempt certain modifying relationships with respect to their environment. From earliest infancy they want "to do something." As they grow older and the aimlessness of infantile manipulation of the environment becomes an organized pattern, this something which they do to the environment turns out to be a modification of it in either a constructive or a destructive direction. We perform creative activity and destructive activity—nothing else. Both forms of activity seem to be related to certain instinctual drives, and a certain kind and amount of destructiveness and a certain amount of creativeness appear in the activities of every human being. As long as an adequate amount of both is possible for an individual, he does not develop a neurosis or a psychosis.

For various reasons—a brain tumor, a hemiplegia, an infection with tuberculosis, a reaction of grief to the death of a daughter, a reaction of fear to the treatment of an employer, a reaction of hate to the infidelity of a husband, an ineradicable memory of overwhelming defeat and inadequacy experienced in childhood—for these and many other reasons, the ability to direct energy in a proper pattern of destructiveness and creativeness fails to develop or to be maintained. The resulting incoordinate, awkward attempts to maintain an adjustment is expensive of energy. The patient carries on with his assigned tasks only under the greatest difficulty, with increasing inefficiency, pain and internal and external dissatisfaction. Perhaps he continues to operate at 40 per cent efficiency plus much complaining, worrying, lamenting and despairing, plus many "patent medicines," osteopathic treatments, periods of absenteeism, week end drunks, acerbities with wife and children, quarrels with fellow employees, foremen and assistants. If his efficiency declines even further, let us say to 20 per cent, he may come to a psychiatrist. The brakes are well set, the heat is enormous, the productivity is minimum, the distress is great.

The absurdity and futility of prescribing rest for such a patient must be apparent. The problem is rather to discover what prodigious internal consumption and blockade of energy has occurred and how it can be directed again to fruitful employment. The technic in doing this is beyond the scope of the paper; it would entail a review of the entire program of psychiatric examination and treatment.

Pari passu with the development of the rest cure there developed in the field of medicine a program of work cure. This concept held that such individuals needed only to be driven to more strenuous efforts, a procedure comparable to driving an overheated brake-set automobile harder and faster. Obviously, this is an even more absurd philosophy than that of the rest cure. It appealed particularly to hardboiled industrialists and misguided Army officers whose conception of neurotic illness is that its victims are lazy liars or yellow dogs, feigning disability to avoid duty.

At first glance, the behavior of the neurotic or psychotic patient would seem to lend support to these emotionally colored judgments of the exasperated practical man of affairs. The modern psychiatric hospital provides abundant opportunities for enlisting the interests of patients¹ and yet despite the efforts of the medical director, the medical staff, the nursing staff and the therapists—despite schedules and regulations and exhortations—many patients manage to evade with an uncanny skill every available opportunity for exercise, constructive craft work, amusement, diversion, recreation and all the other outlets so carefully planned and devised for them. The temptation is to react to this emotionally, forgetting that this is the primary problem of psychiatry. What malignant energy lock has occurred within them that prevents it? What we find almost regularly in psychiatric patients is that they cannot work, they cannot play and they cannot rest. They have to be taught to do all three of these things. Fortunately, in most cases it proves possible to grade the assignments so that patients may be taught to play and taught to work and thus taught to divert available energy toward the construction of patterns of creativeness and destructiveness which can be reemployed usefully in the outside world when the patient has made sufficient progress. Meanwhile of course other types of procedure must be instigated which make more energy available for the development of such patterns.

To teach such individuals how to work and how to play is to teach them how really to rest. This is the function of occupational therapy, recreational therapy, educational therapy and psychotherapy as they are employed in the modern psychiatric hospital.² They seek to make it possible for the patient to find an outlet for his instinctual urges in work and play properly guided, properly taught, properly selected for his special needs, interests and capacities, and properly graded and expanded. All this is in a contrary direction to that of the old plan of enforced rest whereby the patient through moral, physical or chemical restraint was obliged to surrender to idleness and passivity. Both types of treatment were not only ineffective; they were actually deleterious. The reason for this is not far to seek. Patients deprived of physiologic, mechanical and psychologic devices for turning their aggressive energy into batting a ball, digging a trench or making a puppet turn these destructive tendencies in on themselves.³ The man who commits suicide, who kills himself, is often thought of as the paradigm of psychiatric morbidity. He turns all of his aggressive energy on himself and commits a murder with himself as the object. It is quite obvious, of course, that many self-destructive persons do not go as far as murdering the object; they only berate it, abuse it, debauch it, humiliate it, hamstring it, intoxicate it. By it, of course I mean the self; this is the way many people treat themselves. In psychiatry we describe this abuse and mistreatment of the self as the turning inward of aggressive tendencies. The object of psychiatric treatment for such individuals is to turn these aggressive impulses outward, away from the self. Failure to do so results in a virtual suicide, not by placing a gun to the temple or even by

pouring gallons of whisky into the central nervous system, but by the accumulation of hostile feelings associated with self-destructive energy that accomplish the same morbid result. We know that physical exertion, the directed use of the muscles, tends to combat this, and that enforced rest tends to favor it.

Having thus demonstrated as well as I can in the short time allotted to me that rest can be a very dangerous remedy and do a great deal of harm, I should like to end my contribution to this symposium by taking the paradoxical position that rest may also do a very definite amount of good. If one remembers that the psychiatrically disturbed patient who cannot work or play efficiently usually cannot rest adequately, one realizes that definite steps have to be taken to improve this capacity also. It was in that direction that hydrotherapy, prolonged immersion tub baths, wet sheet packs and the like were originally developed, and these are still much employed. Chemical sedatives have improved vastly since the day in which chief reliance had to be put on bromides and opiates. It is possible now to produce sleep in patients whose disturbed emotional conflicts and prevailing fears prevent them from daring to sink into repose without the use of drugs having no deterrent side effects. Some sedatives have the peculiar ability, when administered rapidly, so to modify consciousness and the psychologic architecture as to permit the emergence of what might be described as the indigestible toxic material of the mind. This has been a feature of recent reports from the war theater made by Grinker and Spiegel,⁴ Murray⁵ and others. In some instances exposure to prodigious stress, both physical and mental, has so depleted the energy reserves of combat troops, airplane pilots and shipwrecked merchant seamen that psychiatric syndromes characterized by anxiety, fears, aggressiveness, erratic behavior and other symptoms have emerged. In these conditions prompt and complete rest has proved of enormous benefit, as indicated by the reports of Commander Daniel Blain⁶ of the War Shipping Administration, Public Health Service Clinics, and his associates.⁷ A few nights of sound, protected sleep under quiet, pleasant surroundings with good food and manifested friendliness are often sufficient to restore these individuals to active duty within one to three weeks. Even in these cases, important as is the element of rest, the importance of the psychologic factors of safety, sympathy and admiration are probably equally great. Companionship and planned activities are prescribed as soon as the men are up. It should certainly be borne in mind that these cases represent a war syndrome and are not comparable to any peacetime pictures. There is a vast difference between the man who has worked at full capacity for thirty-six hours without stopping and is then thrown into cold oily waters by a submarine attack and fights for his life in and out of a lifeboat for the next twenty-four hours—there is a vast difference between his need for rest and the need for rest of the average maladjusted, neurotic or

psychotic civilian, whose illness is none the less severe but whose physical energy and physiologic defenses have had no such sudden strain put on them.

CONCLUSION

The concept of rest as a form of treatment in psychiatry arose in an era characterized by the total neglect of the consideration of psychologic factors in the study of human beings. As the mechanistic conception of personality has given way to the dynamic organismic conception, the fallacy of curing psychologic symptoms by merely decreasing muscular activity has become apparent. In the sense of physical inactivity, rest has ceased to be of any importance in psychiatric phenomena. Indeed, the tendency is in precisely the other direction; namely, to utilize rather than to blockade further the available energy of the neurotic or psychotic patient. Such a point of view extends beyond a treatment of conditions formerly described as neuroses and psychoses, however; in arterial hypertension, for example, where there is a vascular response to the anxiety associated with emotional conflict, the former prescription of exercise and work seems to have been a step in precisely the wrong direction. I am confident that the death of some hypertensive patients has been hastened by physicians who removed from them the only available or acceptable form of aggression to which they had had access. When I suggested this a few years ago,⁸ I received numerous letters from internists confirming this opinion on the basis of their own clinical experience. How widely this may apply to other forms of what we formerly called physical illness and which we now, with equal verbal error, sometimes call psychosomatic conditions has been indicated in part by the presentations in this symposium.

The net philosophical import is that successful medicine must envisage the personality as a physiochemo-psychologic unit susceptible of being interpreted and treated from the physical standpoint, the chemical standpoint and the psychologic standpoint, assuming a working knowledge of the instinctual motivations that impel the adjustment patterns of human life.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. HARRISON, EASTMAN, POWERS, DOCK,
GHORMLEY AND MENNINGER

DR. J. ROSS VEAL, Washington, D. C.: Thrombosis of the deep veins of the leg and foot is a common complication in patients who are forced to bed. The more sick the patient, the older the patient, the more sedation we use and the more absolute the rest, the more likely is thrombosis. If we look for this condition, we shall be able to find it. Once we find it, we can do something about it and prevent fatal pulmonary embolism. The veins involved are usually the deep tibial, the superficial veins of the leg and deep veins of the feet. If every doctor who has patients confined to bed would examine the legs and feet daily and look for certain signs, he would be able to detect the thrombosis early. One should ask the patient about any abnormal sensations of the legs as numbness, pain or a sense of coldness. He should look at the legs and feet for changes in color, dilated veins or hemorrhage in the skin or edema. He should palpate the extremity for tenderness of the toes, the feet and the legs. He should also examine the pulses of both legs and feet to determine any diminution of volume. He should detect any sweating of one leg not present in another. If he finds any of these abnormal signs he should accept the possible diagnosis of thrombosis of the deep veins. There is

one aid which may help considerably in confirming the diagnosis, and that is an x-ray examination of the deep veins. In many instances one will be able to demonstrate the thrombosis before other positive signs are present. After diagnosis of thrombosis of the deep veins of the leg, the appropriate vein above the level of the clot should be ligated. The major veins of the lower extremity, the femorals, the iliacs and the vena cava can be ligated even if the patient is extremely ill without causing death. The end results are a shorter convalescence, a better leg and often the saving of the patient's life.

DR. FRANK H. KRUSEN, Rochester, Minn.: I recalled the statement by Dr. George Minot "Rest means many things to many persons." He told of a policeman who was advised to rest and promptly took an automobile drive from Boston to California and back in twelve days. To him rest meant change of activity. Another patient was told to rest in bed. She did go to bed at certain hours each day, but she answered the telephone, jotted down notes, took care of all the family affairs, worked out the problems for the day. Rest to her meant lying in bed. When Dr. Ghormley mentioned Hugh Owen Thomas and when Dr. Menninger mentioned Weir Mitchell I thought of Allen K. Krause's book "Rest and Other Things" and his advice to the physician who cared for the tuberculous patient "Rest must be first, and always first, in the treatment of the tuberculous." I tried to think of some one as influential as Weir Mitchell, Hugh Owen Thomas or Allen Krause who would lead us in the opposite direction, and I couldn't think of any one. I thought perhaps we had been following these physicians a little too blindly. Such blind following of the great physicians of the past has always been one of the weaknesses of the medical profession. Confusion with regard to abuse of rest in the arthritic is due to failure to recognize the difference between complete immobilization of the individual and the avoidance of fatigue. They are entirely different. The patient can avoid fatigue and yet maintain all of the joints in complete mobility. Dr. Philip Hench said "The rest school men have discussed rest so much that I think we are even in danger of over-resting our patient. And the dangers of over-rest in arthritis are as great as if not greater than the dangers of overexercise, because when the patient overexercises he promptly knows he has done wrong because of the increased pain, but when he over-rests the results of over-rest work on him silently and maliciously until one suddenly notes serious if not irreparable contractures."

DR. H. CLOSE HESSELTINE, Chicago: Many patients do not rest even though they are confined to bed. Like all therapies, rest if it is to be used properly must be neither too much nor too little but adequate. The woman in industry has, as a rule, a double problem. One is the care of her home; if she is a mother, the care of her family as well. On the other hand, she must be a sufficiently satisfactory employee to keep her job. Good mothers at times do as much work at home as they do on a regular shift at the plant. This necessitates long hours. Failing to give or provide care for the family may encourage or precipitate a social problem in the community. It is evident to the Committee on the Health of Women in Industry of the Section on Obstetrics and Gynecology of the American Medical Association that we must institute an additional program for both the industrial physician and the obstetrician and gynecologist to bring about a proper cooperation of these two groups. This additional advance will benefit the employee and the employer. There are no reliable, conclusive data to help us on the problems of women in industry. Efforts are now under way, through governmental and other agencies, to collect facts about women employees. From such sources we hope to have better foundation for our recommendations. Dr. Eastman has given you his data specifically on child spacing. One might ask whether the longer spacing interval was volitional or accidental, or whether ill health or other conditions contributed to the longer interval. If ill health was partly responsible for the longer interval, then the explanation for the unfavorable outlook for the longer lapse between pregnancies is explained. Outside of the queen bees and perhaps a few other species, those who reproduce are not given a place

8. Menninger, K.: Emotional Factors in Hypertension. *Bull. Menninger Clin.* 2: 74-88 (May) 1938.

or rest by their society. We have no queens in the human species in this same sense. In the higher levels of life each pregnant animal must supply its own food and self protection. Until we know more we must be very cautious about statements, even though we must be guided by general opinion. Our Committee on the Health of Women in Industry expects to contribute toward a better understanding of women in industry in a fair and equitable manner for both the employer and the employee.

COMMANDER J. MURRAY STEEL, Bethesda, Md. In connection with Dr. Harrison's remarks about uremia in bed, I had the interesting experience of seeing at least three persons whose renal function was poor, who had considerable nitrogen retention, get up about the wards and go home, and at the same time the degree of nitrogen retention diminished considerably. It did not disappear altogether. In a large proportion of patients with chronic rheumatic heart disease who had been in bed for months, when allowed to get up and their activity increased, it was found that the pulse rate and the sedimentation rate and often the fever all disappeared as the mobility of the joints or the function of their hearts appeared to be increased.

DR. D. J. LEITHAUSER, Detroit. Dr. Powers reported a series of 100 surgical patients subjected to "early rising." I have a series of over 1,300 cases in which more than thirty different surgical procedures had been performed—a diaphragmatic herniorrhaphy, splenectomies, gastrointestinal surgery and the like. There was no case of uncontrolled atelectasis in the series. A cough or two at the first out of bed period would invariably expel the mucous plugs. These exercises in some instances were required every hour or two for several days before the lungs would remain clear. There were no deaths from pulmonary embolism in the series. There was 1 case of thrombophlebitis. The patient had a paravertebral injection of procaine hydrochloride. She left the hospital seven days later. There was no embolism in the series. There are precautions that require emphasis in getting patients out of bed "early." One should not employ catgut in long incisions. Catgut gives a foreign protein reaction, particularly heavy catgut. This delays healing, evisceration may result. I employ alloy steel wire in long incisions. There was no evisceration in this series. How should we get a surgical patient out of bed? First the patient assumes the lateral position, then is assisted to a sitting position. Next, the patient stands beside the bed. The presence of palpable rales is then determined by the nurse while the patient coughs; the cough also expels the mucous plugs. A few paces are now taken if the patient's condition permits, and then the patient returns to bed. A chair is not permitted for any length of time at the first or second out of bed period.

COLONEL E. V. AITEN, Rochester, Minn. In the armed forces there are a large number of cases of acute rheumatic fever. The problem of management of subjects with acute rheumatic fever in the Army is not only a problem of management of the individual disease but also the problem of the management of the sick soldier considered in light of his relationship to the Army. The program aside from specific treatment, consists of rest in bed until the subject has had no tachycardia, no fever, no joint manifestations, and until the sedimentation rate and the electrocardiogram have been normal for seven to fourteen days. This program of rest supposedly has two purposes: the prevention of relapse of acute rheumatic fever and the prevention of cardiac damage. In this discussion I will omit the consideration of the question of whether or not recurrence of acute rheumatic fever results from activity. There is no good evidence that it does. Now I come to the questions which I hope our chairman will be able to answer. What is the evidence that rest in bed prevents development of heart disease in subjects with acute rheumatic fever? Secondly, when may persons with acute rheumatic fever and some evidence of cardiac involvement, either myocardial or valvular, be allowed out of bed? Thirdly, when may subjects with

acute rheumatic fever with some type of heart involvement be allowed to resume normal activity? The answers are of great interest. I am reasonably certain that the role of rest in the treatment of acute rheumatic fever has been unduly emphasized. The program as commonly carried out now encourages the development of nonorganic illness which centers about the heart and joints. It is reasonable to ask if harm would result from allowing subjects with acute rheumatic fever to have mild activity, out of bed, whenever they feel well enough. This symposium should encourage physicians to examine critically the present program of prolonged rest in bed as part of treatment of acute rheumatic fever.

DR. DON C. STETSON, Chicago. I have seen the effects of Dr. Harrison's work in the attitude of certain young and enthusiastic practitioners in their treatment of coronary thrombosis in letting their patients up sooner than I think they should. Some ten years ago Dr. Davis and I tied the anterior descending branch of the coronary in dogs and produced an infarct. Some of the dogs were given sufficient sedatives to lie in the cage, others were allowed up and about and others were forced to use the treadmill. Those kept quiet often had healed infarcts that were almost invisible. The healing properties of a young dog are much more rapid and superior to those occurring in an old arteriosclerotic heart. The only aneurysms we saw of the ventricle were in dogs that had exercised. The only cardiac aneurysms that I have seen have been in patients that have not been kept in bed what I think is a long enough period. What that period should be, none of us know. I do know that in a small autopsy material I have seen hearts, the longest seven weeks after the primary thrombus, in which the infarct looked to me like quite soft granulation tissue. I have seen infarcts at the end of three weeks that could only be described as consisting of the material that is seen in a ripe alligator pear. I have my doubts that such patients should be allowed to exercise very early. Dr. Harrison called attention to the psychosis that develops as a result of prolonged bed rest. I have seen very little of it in patients that are told frankly what they have, the reasons for the rest, and what we can expect at the end of that rest period. I cannot quite see having cardiac patients up and about who have edema of the legs and perhaps dyspnea. I would think the two go together. I feel distinctly that those patients should be kept quiet, that there are other methods of taking care of the dangers of venous stasis, which is a very real danger. Dr. Dock stated that emboli from stasis in auricular fibrillation were more frequent with the patient lying in bed than they were when up and about. After twenty five years in the Heart Clinic at the County Hospital I am unable to prove a relationship between bed rest and pulmonary or other embolism from auricular fibrillation.

DR. LOUIS V. KATZ, Chicago, Ill. Rest does not consist only in putting a patient to bed. Emotional rest must also be obtained, worries should be removed, the patient kept from becoming restless and a regimen instituted to make rest less boring. Emotional upsets raise blood pressure and speed up the heart and therefore burden it. Coughing and constipation are other burdens that require treatment. A good night's rest has an amazing effect on cardiac patients. Sedation, including morphine, is an important adjuvant. The patient's position determines how restful his rest may be, the proper use of a bed rest or a reclining easy chair may be indicated. In short, rest is different from just putting the patient to bed. Bad results may not be due to bed rest per se but to the imperfect regimen of rest carried out. In two periods of cardiac convalescence it is safer to err by too long a period of rest than to sin by being less conservative, viz. after a myocardial infarction and after acute rheumatic carditis. I am not concerned that patients with congestive heart failure may not get enough rest because the symptoms and signs will soon put the physician straight. However, following recent myocardial infarction, patients often rebel against the restriction imposed because they feel all right and consider the physician overcautious. The infarcted region

takes a long time to heal, and care must be taken that this region doesn't "blow out" because the heart has not had a sufficient period of relative inactivity. It is better to play safe than to be sorry. The same principle of protracted rest is applicable to active rheumatic fever. A sharp distinction should be drawn between the stages of rheumatic heart disease when the heart is suffering from the scars of the infection and the period when the inflammatory process is still smoldering. As long as there is evidence of a smoldering inflammation of the heart, it is good therapy to keep the patient at rest. Dr. Harrison's fear that in chronic coronary disease invalids may be made by overpampering is justified. There is a tendency to overindulge such patients. However, chronic coronary disease often occurs in aggressive individuals who fail to make sufficient readjustment in spite of symptoms. A real service can be rendered by the physician who can discuss the situation with such a person and help to balance properly his existence between too much and too little activity.

DR. NICHOLSON J. EASTMAN, Baltimore: Dr. Hesselstine asked if the interval was the effect of accident, the effect of intentional child spacing because of social reasons, or the effect of intentional spacing because of disease processes. In a great majority of cases the interval was accidental. In a certain minority it was intentional because of social reasons, particularly among private patients, and in a negligible minority it was intentional because of medical indications.

DR. JOHN H. POWERS, Cooperstown, N. Y.: This program was instituted at the Mary Imogene Bassett Hospital two and one-half years ago. At first we were apprehensive about the results that might be expected. Consequently we started getting patients up on the fourth day, then on the third day, later on the second day and finally on the first day. Now all patients are ambulatory on the first day after all major operations, except in the presence of generalized peritonitis. By that I mean bacterial peritonitis. Patients do get up on the first day after closure of a perforated duodenal ulcer; no untoward effects have been observed. Certain things are compulsory if early activity after operation is to be permitted. Most imperative is accurate reapproximation of tissue with interrupted sutures, preferably of a nonabsorbable nature. I use silk almost entirely. In about 85 per cent of the cases reported silk was used without additional supporting sutures. If catgut is to be used, it is probable that stay sutures of nonabsorbable nature, silkworm gut or silver wire, should be used in conjunction. My experience with catgut alone has not been adequate to form an opinion as to the safety of its use as an unsupported suture material, if early activity is to be permitted. Postoperative thrombosis and embolism comprise two of the unpredictable complications and unsolved problems of surgery. Early activity after operation, walking about, deep breathing and muscular exercises in bed during the periods when the patient is recumbent will do much to reduce the incidence of postoperative thrombosis in the deep veins of the legs and the often fatal catastrophe of pulmonary embolism.

DR. WILLIAM DOCK, Los Angeles: I should like to make a correction. I participated in a symposium presided over by Dr. Gold and have been credited with Dr. Gold's statistics. Dr. Gold was studying the effect of digitalis on auricular fibrillation and brought ambulatory patients into the hospital. These patients were given enforced bed rest. Dr. Gold gave us the actual incidence of pulmonary embolism in this group of patients who were taken out of their ambulatory life for special study as compared with a similar group still attending the clinic. I don't think the emboli came from the auricle; I think they came from the leg and that the patients had thrombosis occurring after a week or two of bed rest. When a patient is put in bed and not allowed to sit on a commode once or twice a day, you are doing something to him that may be unnecessary. I haven't heard anybody introducing evidence that a cardiac patient is better off if he lies in bed than if he sits in an armchair. It is much easier to take care of people with myocardial infarction if they are told that you are going to keep them in one room for three months than if told that

you are going to keep them in bed six weeks. The patient gets along much better if allowed to sit in an armchair and sleep comfortably at night, than if kept in bed all day with the indigestion and discomfort of complete bed rest. I agree with Dr. Sutton that people should not run up and down stairs after myocardial infarction, but I don't see that that has any bearing on the point raised here.

DR. KARL A. MENNINGER, Topeka, Kan.: This symposium should begin next year with a discussion of what rest is supposed to mean, whether one is speaking about the posture in which an individual is placed in the sickroom (in bed or in a chair) or whether one refers to the degree of muscular activity that is to be permitted a patient, or whether we have in mind some kind of psychologic rest. The latter concept was introduced by one of the discussers who spoke of a man supposedly resting in bed with telephones and a radio going; this, he said, is not rest. To this I would react by declaring again the basic facts which psychiatric experience has demonstrated. The things that disturb the rest of people are not what they hear on the radio; they are what is in their hearts. It is what has happened to them, what is going to happen to them, what isn't going to happen to them, their own fears, their own disappointments, their own misgivings, theirs, not the radio's. The things that disturb people are not what come from outside; they are what come from inside. As a psychiatrist who sees some but relatively few patients with heart disease, I would certainly see no reason to proscribe the radio. I see a great deal of reason to urge that the cardiologist who really wants his patients to rest should make some attempt to remove from that patient the things that really prevent him from resting, the things that are inside him.

DR. TINSLEY R. HARRISON, Dallas, Texas: I do not believe any one knows the extent to which the activity of the rheumatic process is influenced by the degree of inactivity of the patient. Dr. Sutton found that while exercise carried out by his dogs within the first few days after ligation of a coronary artery produced a larger scar, similar exercise begun six days after the operation had no effect. Is that not correct?

DR. SUTTON: That is right.

DR. HARRISON: According to that, the dog should not exercise on the treadmill for six days. I think we would all agree with that. I too would like to emphasize the dangers of recumbency for a patient with congestive failure. Water in the legs is unsightly, but water in the lungs may be fatal. A person with dropsy gets more water in the lungs when he lies down, because in the body the law of gravity still holds. Concerning the "mushy" infarct: If a patient has a slowly developing infarct, the lesion may remain soft for several weeks. In such an instance the alterations in the leukocyte count and in the sedimentation rate will tend to persist. In my opinion patients should be kept at rest—although not necessarily in the recumbent position—until such manifestations have disappeared and then for perhaps two weeks longer. I agree with Dr. Katz that rest should be neither neglected nor abused. The question is What is neglect and what is abuse? In this regard one has to distinguish between rest for the patient as a whole and rest for the heart. There is no doubt that, as shown by the metabolic rate, the body as a whole expends less energy in the recumbent position. The work of the heart depends mainly on the output and the blood pressure. The blood pressure, when a person is sitting, is—as a rule—a little higher than during recumbency. However, in elderly persons it is often somewhat less in the sitting position. We know that the cardiac output per minute is definitely less sitting than lying. The work of the heart per minute is either about the same or somewhat less when a person sits than when recumbent. Since the heart rate is faster, the work of the heart per beat is definitely less in the sitting position. So far as cardiac rupture is concerned, it is probably the work per beat that is of importance. When we let the patient's body have a little activity, we may be actually resting his heart somewhat more.

THE FUTURE OF PHYSICAL MEDICINE

WITH SPECIAL REFERENCE TO THE RECOMMENDATIONS OF THE BARUCH COMMITTEE ON PHYSICAL MEDICINE

FRANK H. KRUSEN, M.D.

ROCHESTER, MINN.

At last the long delayed development of physical medicine seems to be at hand.

Physical medicine includes the employment of the physical and other effective properties of light, heat, cold, water, electricity, massage, manipulation, exercise and mechanical devices for physical and occupational therapy in the diagnosis or treatment of disease.

Physical medicine is applied biophysics. Dr. Alan Gregg,¹ medical director of the Rockefeller Foundation, said recently "Among my major hopes, let me record the wish that biophysics may be soon recognized as the brother of biochemistry, even if the time is now too late to consider it a twin. . . . One of the natural outgrowths of such a preclinical science might be the now long overdue development of physical therapy in this country."

Physical agents are employed not only for therapy but also for diagnosis; therefore the term physical medicine, long in use in England, is gradually replacing the designation physical therapy in this country. Physical medicine is the more generic and more inclusive term and as defined herewith it embraces physical therapy, occupational therapy and the employment of physical agents for diagnostic purposes.

Physical medicine has developed to a point at which it must be considered as a separate and distinct medical specialty. The recent tremendous interest in this special branch of medicine, culminating in the activities of the Baruch Committee on Physical Medicine, indicates that physical medicine has at last come of age.

Dr. Frank Ober,² assistant dean of Harvard Medical School, told me recently "The last war established orthopedic surgery as a recognized specialty. This war may well do the same for physical medicine." But the war is not solely responsible for the sudden maturing of physical medicine.

Since the pioneering days of Dr. Simon Baruch, the father of hydrotherapy in America, there has been a gradual unfolding of all phases of physical medicine until now it is beginning to burst into full scientific bloom.

This development is perhaps due to natural evolution. Dr. W. C. Davison,³ dean of Duke University School of Medicine, has mentioned that medicine has gone through four periods: (1) a primitive period in which the employment of physical agents played an important role, (2) the renaissance period, (3) the period of pharmacy and (4) the modern period during which we have emphasized successively prevention, pathology, bacteriology, biochemistry, surgery, specific therapy and now we are back to nonspecific and physical therapy, which, Davison concluded, "demands increased study and greater use." We must treat the patient as well as the disease.

From the Section on Physical Medicine, Mayo Clinic.
Read before the Section on Experimental Medicine and Therapeutics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

1. Gregg, Alan: A Critique of Medical Research, *Scient. Monthly* 58: 365-372 (May) 1944.

2. Ober, F. R.: Personal communication to the author.

3. Davison, W. C.: The Evolution of Therapy—A Plea for Treating the Patient as Well as His Disease, *South. Med. & Surg.* 100: 457-458 (Oct.) 1935.

The Council on Physical Medicine of the American Medical Association and more recently the Committee on American Health Resorts have contributed largely toward the development of physical medicine.

Still more recently the National Foundation for Infantile Paralysis, on the advice of a distinguished group of scientists headed by Dr. Walter Cannon, recognized the need for the advancement of physical medicine and provided the first large grant for establishment of a center for teaching and research in physical medicine at the University of Pennsylvania.

The National Research Council has recognized the need for more study of the employment of physical agents; particularly in the management of peripheral nerve injuries, and has made numerous grants for research in this field.

Finally our famed elder statesman and humanitarian Mr. Bernard M. Baruch, impressed with the possibilities of physical medicine by his father, the late Dr. Simon Baruch, appointed a committee headed by Dr. Ray Lyman Wilbur to make a survey and to report on the programs deemed best for adequate development of physical medicine in the United States.

This survey committee was composed of eight men: (1) Dr. Ray Lyman Wilbur, Stanford University, Stanford University, Calif. (chairman); (2) Dr. William T. Sanger, Medical College of Virginia, Richmond (vice chairman); (3) Dr. Frank H. Krusen, Mayo Clinic, Rochester, Minn. (director-secretary); (4) Capt. Charles F. Behrens (MC), U.S.N., Bethesda, Md.; (5) Dr. Carl R. Comstock, Saratoga Springs, N. Y.; (6) Dr. John S. Coulter, Northwestern University, Chicago; (7) Dr. Kristian G. Hansson, Cornell University, New York, and (8) Lieut. Col. Benjamin A. Strickland, Jr., M. C., U. S. Army, Tucson, Ariz.

Eight subcommittees, composing a group of forty scientists, were appointed. These subcommittees dealt with the following phases of physical medicine: (1) teaching, (2) basic research, (3) clinical research, (4) public relations, (5) rehabilitation, (6) hydrology and health resorts, (7) occupational therapy and (8) prevention and body mechanics.

The subcommittees, in turn, consulted directly more than 400 outstanding scientists concerning various phases of their problem.

The survey was begun on Nov. 1, 1943 and the final meeting of the committee was completed on Jan. 30, 1944.

NEEDS OF PHYSICAL MEDICINE

It is obvious that the chief needs for proper development of physical medicine are:

1. An adequate supply of physicians who can teach and use physical medicine.
2. More extensive basic and clinical research in physical medicine.
3. Proper use of physical medicine in relation to wartime rehabilitation and peacetime physical preparedness.

On completion of its survey, the committee recommended the following program for sound development of physical medicine on a lasting basis:

Teaching.—To develop an adequate program in teaching of physical medicine there is need for:

1. More teachers of physical medicine. (This is the pre-eminent need.)
2. Several extensive graduate courses to train teachers of physical medicine.

3. A central body to promote education in physical medicine.
4. Establishment of three to five centers of physical medicine at large medical schools.
5. Establishment of fellowships in physical medicine.
6. Better teaching of physical medicine to undergraduate medical students.
7. More physical therapy and occupational therapy technicians.
8. A recruitment program to obtain these technicians.
9. Better teaching and correlation of the work of these technicians.

Basic Research.—1. Controlled scientific investigation of the fundamental aspects of physical treatment of disease is of utmost importance in any program which is established for the advancement of physical medicine.

2. Basic research can be organized most economically and effectively where there are expert investigators and when it is associated directly with clinical research and practice.

3. Means should be provided for bringing medical research laboratories into easy contact with the research laboratories of academic institutions and commercial organizations.

4. Quick results are not to be expected from any plan for adequate development of basic research.

Clinical Research.—1. Approved methods for evaluation of clinical research should be employed.

2. Basic and clinical research should go hand in hand.

3. Teaching of physical medicine is done best at medical schools which are conducting adequate clinical research.

Public Relations.—1. Physical medicine has not been given the recognition that it merits by the medical profession or by the public at large.

2. Wide dissemination of appropriate information is necessary. Only through financial support and adequate understanding can a long range program of general information be developed. Intelligent and discriminating publicity which will reach all elements of our population is required.

Rehabilitation.—Medical rehabilitation is the restoration of people handicapped by disease, injury or malformation as nearly as possible to a normal physical and mental state. Medical rehabilitation fills the gap between the customary end point of medical attention and the real necessities of many patients.

In 1940, 4,000,000 persons suffered from permanent physical disabilities and the annual increment was 800,000. In those prewar days the figures were enormous, and since the war they have increased to staggering proportions.

1. Wartime and postwar physical rehabilitation concerns not only the armed services but also industry and the Veterans Administration.

2. The most immediate and pressing problem is to provide needed personnel.

(a) There is a definite shortage of physicians trained in physical medicine who would be capable of directing rehabilitation services.

(b) There is an acute generalized shortage of physical therapy and occupational therapy technicians. Only one fifth the number required is now available.

3. Industry should cooperate in the placement of handicapped persons in suitable positions. It has been estimated that for every dollar spent for rehabilitation \$47 is returned to society.

4. Industrialists need further information concerning the valuable services which partially disabled persons can perform.

5. Industrial physicians need proper knowledge of rehabilitation problems.

6. Cooperation between labor, industry and medicine is essential.

7. Liaison between various rehabilitation services should be good.

8. There is need for a carefully organized over all scheme for rehabilitation of war casualties.

Hydrology and Health Resorts.—There is need for:

1. Basic research in laboratories where there can be sound evaluation of the effects of hydrotherapeutic procedures and spa therapy.

2. Improved teaching of hydrology and spa therapy in medical schools.

3. Better medical supervision of the therapeutic procedures employed at health resorts.

4. More extensive use of existing health resorts for rehabilitation of war casualties.

5. Efforts to prevent the alarming tendency to abandon the use of valuable spas.

Occupational Therapy.—Occupational therapy provides a graded program of activity to restore maximal physical and mental function or seeks to divert a person and improve morale by arousing his interest, courage and confidence.

There is need for:

1. Medical direction of hospital departments of occupational therapy. This is considered necessary for their proper development.

2. Encouragement of programs for training of volunteer aides to assist qualified occupational therapy technicians.

3. Appointment of a qualified field secretary in occupational therapy to assist in spreading correct information, recruiting of students and standardizing courses.

4. Establishment of an information center to demonstrate new educational methods, corrective techniques and apparatus employed in modern occupational therapy.

5. Development of a program to encourage more teaching of occupational therapy as part of a suitable course in physical medicine in the medical schools.

Curative Workshops: Curative and sheltered workshops in which both occupational and physical therapy are administered for rehabilitation of the disabled are becoming increasingly useful in various communities. They should be operated under direct medical supervision. Because of their value in relation to the war, their further development should be encouraged and, since physical and occupational rehabilitation should often be given simultaneously with medical and surgical treatment, curative workshops should be organized in conjunction with general hospitals.

Rehabilitation and Industry: Both management and labor should be made cognizant of the importance of rehabilitation centers in which injured war workers can

be given occupational therapy, vocational training and avocational retraining.

Body Mechanics.—Body mechanics is the mechanical correlation of the various systems of the body. Normal body mechanics obtains when this mechanical correlation is most favorable to the function of these systems.

There is a need not only for further investigation of the mechanical correlation of the various systems of the body from the standpoint of static posture but also for a more detailed study of human motion. Furthermore, there is a definite need for careful study of the various manipulative procedures which are employed therapeutically to alter the structural mechanics of the human body.

SUMMARY OF RECOMMENDATIONS OF THE COMMITTEE

Immediate Program.—1. Organization of a central office. The committee believes that there will be need for the establishment of a central office with staff, which should serve as a sympathetic supportive mechanism, to promote and to coordinate, rather than to direct, research in physical medicine. (This office has been established at 597 Madison Avenue, New York 22, with the following personnel: Dr. Ray Lyman Wilbur [chairman], Dr. Frank H. Krusen [director], Dr. Ernest J. Jaqua [educational director] and Miss Grace Keefe [executive secretary].) The committee suggests that this central office should include:

(a) A governing board, whose duty should be to distribute the original funds provided by the donor or other funds which may be given for similar purposes. (An administrative board, consisting of Dr. Wilbur, Dr. Krusen and Miss Mary A. Boyle, has been appointed.)

(b) An advisory board of experts in physical medicine and related medical fields, to give advice concerning the scientific aspects of research and teaching in physical medicine. (A scientific advisory committee has been established. This committee has the following members: Dr. John Stanley Coulter, Chicago, professor of physical therapy, Northwestern University Medical School and chairman of the Council on Physical Medicine of the American Medical Association; Dr. John F. Fulton, New Haven, Conn., Sterling professor of physiology, Yale University Medical School; Dr. Charles Gordon Heyd, New York, professor of surgery, New York Post-Graduate Medical School, Columbia University, and Past President of the American Medical Association; Dr. Andrew C. Ivy, Chicago, Nathan Smith Davis professor of physiology and head of the department of physiology, Northwestern University Medical School, and consultant to the Bureau of Medicine and Surgery, Navy Department, and to the Planning Division of the Office of the Quartermaster General of the Army; Dr. Chauncey D. Leake, Galveston, Texas, vice president and dean, Medical Branch of the University of Texas; Dr. Frank R. Ober, Boston, John and Buckminster Brown clinical professor of orthopedic surgery and assistant dean in charge of graduate courses, Harvard Medical School; Dr. Winfred Overholser, Washington, D. C., superintendent of St. Elizabeth's Hospital [Washington, D. C.] and professor of psychiatry, George Washington University School of Medicine, and chairman of the Committee on Psychiatry of the National Research Council; Dr.

Francis O. Schmitt, Cambridge, Mass., professor of biology and head of the Department of Biology and Biological Engineering, Massachusetts Institute of Technology.)

2. Establishment of teaching and research centers in physical medicine at interested medical schools. The committee recommends:

(a) That certain medical schools which are interested should be given early opportunity to determine whether or not they desire to undertake more extensive programs in physical medicine. Furthermore, it is recommended that support be given to the enlarged teaching and research projects in physical medicine in the schools which are selected. These schools should be provided with the subsidies needed for enlargement of their programs and allowed complete freedom in development of their projects. (Three centers have been subsidized.)

(b) That all of the medical school centers of physical medicine promote the training of teachers (both medical and technical) in the basic sciences and clinical aspects of physical medicine. (Such centers at a few of our larger interested medical schools could supply the teachers so badly needed in many of the other medical schools. Eventually all approved medical schools should provide adequate teaching of physical medicine.)

(c) That one of the medical school teaching and research centers might become a model center in which all phases of physical medicine, including physical therapy, occupational therapy, electronics, hydrology, climatology, manipulative procedures and physical rehabilitation could be developed. (Columbia University College of Physicians and Surgeons has been given \$400,000 to establish this model center.)

(d) That one of the research and teaching centers devote its major attention to the problems of hydrology, climatology and spa therapy. (The Medical College of Virginia has been given \$250,000 to establish this center.)

(e) That one of the centers of physical medicine devote its major attention to the preventive and manipulative aspects of the structural mechanics of the human body. (New York University has been given \$250,000 to establish this center.)

(f) That because of the increased importance of electronics and other physical agents, one of the centers of physical medicine promote the coordination of the work in research laboratories devoted to projects in physical medicine with the work in other research laboratories, commercial and academic, in the hope of furthering the development of electronic and other physical equipment which could be employed in research in, and clinical application to, physical medicine.

(g) That one of the centers on physical medicine promote special clinical investigations of the psychologic and psychiatric aspects of physical medicine, with special reference to a study of the value of personal contact between physician and patient, including an investigation of the psychic effect of the "laying on of hands."

(h) That all of the centers for physical medicine promote a program for better coordination of physical therapy, occupational therapy, physical rehabilitation and spa therapy.

(i) That there should be provided a combination, or team, of workers at each center for physical medicine

(a specialist in clinical physical medicine and appropriately trained and interested laboratory scientists) to coordinate their work and to attract to the center other investigators and workers (both medical and technical).

(j) It is essential that centers training physicians and technicians should stress the importance of direct medical supervision by qualified physicians of technicians' work and also the importance of proper training of technical personnel to assist these physicians. Only when both physicians and technicians are thoroughly trained, and they appreciate each other, can there be effective treatment of the patient by physical measures.

3. Establishment of fellowships and residencies in physical medicine. The committee recommends:

(a) That support be given to the establishment of fellowships and residencies for interested young physicians, and other scientists, who can be trained in the teaching of such subjects as clinical physical medicine and basic research in physical medicine.

(b) That the previously mentioned centers for physical medicine consider training such fellows in hydrology, climatology and spa therapy, as well as in electronics, physical rehabilitation and manipulative procedures, and that special attention be given to kindred subjects, such as industrial medicine, treatment of the aged and treatment of rheumatic diseases, diseases of the blood vessels and diseases of the nervous system. (One hundred thousand dollars has been set aside for provision of such fellowships.)

4. Promotion of teaching of, and research in, physical medicine in all approved medical schools. Many of the medical schools have expressed interest in improving their teaching programs in physical medicine to meet the demands of wartime and postwar rehabilitation. It is recommended that:

(a) Support be provided to improve curriculums in physical medicine, in graduate medical schools, undergraduate medical schools and technicians' schools.

(b) Support be given to teaching projects by supplying equipment, expert advice and other needs.

(c) Teaching projects in physical medicine in all of the sixty-five medical schools of the United States should be encouraged, and there should be included in such teaching projects consideration of all phases of physical medicine, including occupational therapy, manipulative therapy, spa therapy, climatology and physical rehabilitation. Physical medicine should be presented as a required course in every medical school. It is required just as much as any other branch of medicine.

(d) Subsidies be provided for a "circuit rider" who is a qualified and outstanding expert in physical medicine to visit and to assist deans and key teachers of interested medical schools in organizing teaching and research programs and developing separate departments of physical medicine. (Many of our medical schools do not now have qualified teachers of physical medicine and will need assistance in finding instructors.)

(e) Support be given to permit scientific trips for teachers and research workers in physical medicine, with special emphasis on conferences between workers at physical medicine centers. The underwriting of an annual meeting of the personnel of the various centers

would be valuable. Invited speakers could engage in symposiums, and recent advances could be discussed.

(f) Support be provided for exploring the possibility of coordinating more fully the practice of physical medicine with other special medical fields, such as psychiatry, dermatology, neurology, orthopedics, industrial medicine, rehabilitation and geriatrics.

(g) Support be provided for development, at certain interested medical schools, of short graduate courses in physical medicine for practicing physicians.

(h) Support be given for the development, at certain interested medical schools, of postwar "refresher" courses in physical medicine for medical officers who have had some previous training in physical medicine and who are returning to civil life.

(i) Support be given to the building up of a medical film library and of other visual and pedagogic aids dealing with various phases of physical medicine and with physical rehabilitation.

(j) A special prize be awarded, at intervals, for any suitable outstanding contribution to the field of physical medicine in the hope of stimulating the production of superior scientific presentations.

(k) Support be given for the financing of the preparation and publication of scientific books and monographs on physical medicine, including suitable textbooks for technicians and possibly also for the publication of the report of an annual symposium presented by workers at participating institutions. (One hundred thousand dollars has been set aside for support of these projects.)

5. Preparation of reports by the committee. It is recommended that the committee prepare:

(a) A special concise report for Mr. Baruch. (This was submitted and Mr. Baruch has given an initial sum of \$1,100,000 to activate the program.)

(b) A complete printed report on the findings of the committee for the information of the medical profession and the public at large. (This has been published in a 120 page booklet, which can be obtained free of cost from the Baruch Committee on Physical Medicine, 597 Madison Avenue, New York 22.)

(c) Certain more detailed reports on specific phases of physical medicine which have been investigated by the committee, for the information of physicians, technicians and laymen. (These will be prepared later.)

6. Promotion of wartime and postwar physical rehabilitation. Because of the constantly increasing responsibility and the urgency required to meet the emergency conditions, it is recommended that prompt steps be taken for meetings of a special committee which will coordinate and correlate all matters pertaining to basic research and rehabilitation in Army, Navy and civilian life; therefore it is recommended that support be given promptly:

(a) To wartime physical rehabilitation projects now on their way and to the establishment of a number of new ones.

(b) To the promotion of a joint national program for the recruitment of physical and occupational therapy student technicians.

(c) To a program for promotion of the use of Army and Navy spa resorts as convalescent and rehabilitation centers.

(d) To plans for acceleration and modification of occupational therapy technical training courses in order to meet present day rehabilitation needs.

(e) To the subsidizing of technical field secretaries in physical therapy and occupational therapy to coordinate the teaching in technicians' schools in order to meet the demands of wartime rehabilitation. [A committee on war and postwar physical rehabilitation and reconditioning has been established to coordinate these efforts. This committee has the following members: Major Walter E. Barton, M. C., A. U. S., Washington, D. C., assistant director of the Reconditioning Division and chief of the Blind and Deafened Rehabilitation Branch, Office of the Surgeon General, War Department; Capt. Charles F. Behrens (MC), U.S.N., Bethesda, Md., chief of the Radiological Service, Naval Medical Center; Dr. Dean A. Clark, senior surgeon (R) U. S. P. H. S., Washington, D. C., chief medical officer, Office of Vocational Rehabilitation, Federal Security Agency; Dr. Charles M. Griffith, Washington, D. C., medical director, U. S. Veterans Administration; Capt. Frederick A. Jostes (MC), U.S.N.R., Washington, D. C., Office of Rehabilitation, Bureau of Medicine and Surgery, Navy Department; Capt. Howard Montgomery (MC), U.S.N., Washington, D. C., chief of rehabilitation, Bureau of Medicine and Surgery, Navy Department; Col. Howard A. Rusk, M. C., A. U. S., Washington, D. C., chief of Convalescent Division, Office of the Air Surgeon, War Department; Mr. H. V. Stirling, Washington, D. C., director of the Vocational Rehabilitation Service, Veterans Administration; Lieut. Col. Benjamin A. Strickland Jr., M. C., U. S. Army, Tucson, Ariz., commanding officer, A. A. F. Regional Station Hospital, Davis-Monthan Field, Tucson, Ariz., and formerly head of the Physical Therapy Department, Walter Reed General Hospital; Col. Augustus Thorndike, M. C., A. U. S., Washington, D. C., director, Reconditioning Division, Office of the Surgeon General, War Department, and associate in surgery, Harvard Medical School (on leave of absence), and Dr. William S. Tillett, New York, professor of medicine, New York University College of Medicine, and chairman of the Committee on Convalescence and Rehabilitation of the Division of Medical Sciences, National Research Council.]

Eventual Program.—In conjunction with the eventual program, the committee recommended simply the promotion of certain general projects for the advancement of physical medicine and the adoption of certain resolutions concerning projects on which the committee looked with favor. Space does not permit their discussion here, but this information will be found in the printed report.

REACTIONS TO THE PROGRAM THAT WAS SUGGESTED BY THE BARUCH COMMITTEE ON PHYSICAL MEDICINE

Immediately on announcement of the program of the Baruch Committee on Physical Medicine, widespread approval and enthusiastic endorsement of the project were received. Scientists and laymen alike have been prompt in praising this effort. This led Mr. Baruch to comment that he had never seen anything with which he had been connected—"even the work in the war"—receive such amazingly sympathetic treatment. Leaders in military medicine and in medical science in general gave enthusiastic approval.

In closing, it seems pertinent to quote a few of these statements:

MAJOR GEN. NORMAN T. KIRK: "The Medical Department of the Army is vitally concerned with any new scientific enlightenment in this field, especially as it pertains to reconditioning of wounded soldiers and sailors. You are to be highly commended for the inauguration of a much needed scientific approach to the physical aids to medicine and especially its bearing on the program of restoration of function and salvage of manpower."

VICE ADMIRAL ROSS T. MCINTIRE: "The Medical Department of the Navy is in complete accord with the principles and recommendations laid down in your report to Mr. Baruch. I can assure you that the Bureau of Medicine and Surgery will give every assistance possible to the successful carrying out of your program."

MAJOR GEN. DAVID N. W. GRANT: "Mr. Baruch and your committee have rendered an invaluable service, and now, with the establishment of a permanent committee and the splendid endowment fund, the work in this field is bound to be greatly accelerated and should make valuable contribution both to military and to civilian medicine."

GEN. FRANK T. HINES: "A splendid opportunity for public service exists in the field contemplated. I will give it my full cooperation and whatever help I can to make it a success."

DR. LEWIS H. WEED, Chairman, Division of Medical Sciences, National Research Council, Washington, D. C.: "I have carefully read the tentative report of the Baruch Committee on Physical Medicine. . . . Please know that I am tremendously interested in the whole potential program of the Baruch committee. It represents a most needed development in this country and I am sure that progress will be forthcoming by proper contemplation of the important initial steps."

DR. FRANCIS O. SCHMITT, Massachusetts Institute of Technology, Cambridge, Mass.: "I should like to express great admiration and appreciation for the thoroughness with which the committee has explored the various possibilities in this important field and for the concise manner of presentation of the conclusions in the report. It is a monumental document, and, if the major points in the program can be brought to realization, medicine and the general public will be greatly indebted to your committee."

DR. EMORY W. MORRIS, President, W. K. Kellogg Foundation, Battle Creek, Mich.: "I have reviewed the report of the Baruch Committee on Physical Medicine with a great deal of interest. I agree with the report in general; in fact, it is excellent."

DR. DONALD C. BALFOUR, Director, Mayo Foundation, Rochester, Minn.: "I am gratified that such a complete and comprehensive report on the status of physical medicine has been made in such a short time. . . . Anything that will contribute to the better physical and mental health of the people of this country and to the development of teaching methods should be encouraged to the utmost, and I am sure that the general objective of the Baruch Committee will meet with an enthusiastic response. Mr. Baruch's generous gift in support of the program of the committee is another evidence of his keen vision and kindly altruism."

DR. ALAN GREGG, Director of Medical Sciences, the Rockefeller Foundation, New York: "I would like to convey to you my admiration for the work you have done, since it is a very definite accomplishment, and something that I am proud to be related to, even in a very secondary role."

Up until recently with regard to the advancement of physical medicine, as with the weather, every one has talked about it but no one has done anything. Now it is apparent that something very definite is being done and that my opening statement is justified. At last the long delayed development of physical medicine seems to be at hand.

Clinical Notes, Suggestions and New Instruments

PROTECTION OF DOCTORS AND NURSES WHILE SPRAYING THROATS

CAPTAIN R. V. L. CAMPBELL
MEDICAL CORPS, ARMY OF UNITED STATES

The accompanying sketch illustrates a method of protecting nurses and doctors while spraying throats with an atomizer. The x-ray film affords good visibility and protects not only the face but the hand of the operator if the film is extended

Method of protecting doctors and nurses while spraying throats.

low enough to cover the hand holding the atomizer. This can be made in five minutes from the materials usually found in a doctor's office

A CLAMP TO HOLD INTRAVENOUS NEEDLE IN PLACE

MAJOR LOUIS K. PITMAN
MEDICAL CORPS, ARMY OF THE UNITED STATES

This is a simple device for holding an intravenous needle in place. It consists of a clamp which fits comfortably around the forearm without constricting the blood supply, in the same manner as a bicycle clamp fits around the trouser cuff. A

Clamp to hold intravenous needle in place

smaller clamp mounted on a swivel which also allows some forward and backward movement is attached to the larger clamp. This small clamp holds a glass tube into which a needle is fitted. The needle is thus kept in a steady position and the use of adhesive tape is eliminated.

The clamp can be put in place and removed very quickly and easily.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin E. Smith, M.D., Secretary

ESTROGENIC SUBSTANCES (Water soluble).—Premarin.—An amorphous preparation containing the naturally occurring, water soluble, conjugated forms of the mixed estrogens obtained from the urine of pregnant mares.

The principal estrogen present in estrogenic substances (water soluble) is sodium estrone sulfate. Varying small amounts of other equine estrogens and relatively large quantities of non-estrogenic material are also present in the mixture. The total estrogenic potency of the preparation is expressed in terms of an equivalent quantity of sodium estrone sulfate.

Actions and Uses.—Water soluble estrogenic substances are used in the same conditions for which other estrogenic substances are employed.

Dosage.—For the control of menopausal symptoms, 1.25 mg is usually sufficient. If after a few days of treatment the response is not satisfactory, the dose may be increased. After symptoms have been brought under control the dosage can usually be reduced. For the treatment of senile vaginitis, kraurosis vulvae and pruritus vulvae, 1.25 to 3.75 mg daily should be sufficient.

Preparation —

Estrogenic substances (water soluble) may be prepared in the following manner. To fresh urine from mares pregnant five months or longer, sufficient xylene is added to prevent hydrolysis of conjugated estrogens. The urine is then concentrated under reduced pressure at 40 to 50°C, the pH being maintained at or near neutrality. The urine concentrate is extracted several times with water saturated butyl alcohol. The butyl alcohol extracts are washed several times with tenth normal sodium hydroxide, then twice with small volumes of water and then concentrated to a small volume under reduced pressure at 40 to 50°C.

The concentrate is taken up in acetone and, after the insoluble material has been removed, the acetone solution is concentrated to a small volume. The acetone concentrate is treated with an excess of ether and the precipitate obtained is removed and dried. This precipitate, which varies in color from reddish brown to almost white, is an amorphous, hygroscopic powder possessing a characteristic odor. It is soluble in water, dissolving freely to form a pale yellow solution, soluble in alcohol and acetone, insoluble in benzene and ether.

Estrogenic substances (water soluble) may also be removed from the urine of pregnant mares by selective adsorption and elution. The eluate may be purified by solvent partition and finally reduced to powder in a vacuum dryer.

Estrogenic substances (water soluble) are assayed chemically by a modification of the phenol sulfonic acid colorimetric method introduced by Kober and biologically by oral administration to adult ovariectomized rats, using the technique of Kahut and Doisy. The standard of reference for the chemical assay is the international standard for estrone. This standard being inapplicable to the biologic assay of conjugated estrogens in the rat assay biologic variation is controlled by the use of a house standard preparation of conjugated estrogens.

PROBLEMS IN MEDICAL EDUCATION

The Council on Medical Education and Hospitals presents a series of articles on topics of current major importance in medical education. The first of these is a report on further education desired by medical officers after the present war. This study is being conducted by the Committee on Postwar Medical Service, with which the Council on Medical Education and Hospitals operates in close collaboration. This committee was established in February 1943 by the American

Medical Association with the cooperation of the American College of Physicians and the American College of Surgeons. There is also representation on the committee from the Association of American Medical Colleges, the American Hospital Association, the Catholic Hospital Association, the Federation of State Medical Boards of the United States, the Procurement and Assignment Service, the Advisory Board for Medical Specialties and the Veterans Administration.

FUTURE EDUCATIONAL OBJECTIVES OF MEDICAL OFFICERS

Harold C. Lueth, Lieutenant Colonel, M. C.

Surgeon General's Liaison Officer

Objectives in future medical educational training were derived from information from the results of returned questionnaires of medical officers, a review of the probable educational facilities that will be available to veterans after the war, official actions of the Council on Medical Education and Hospitals, the Advisory Board for Medical Specialties and other representative bodies and informal discussions with medical officers, deans and leaders in medical education and hospital administration.

At the request of the Committee on Postwar Medical Service a questionnaire was devised and mailed to 3,000 medical officers on duty with the armed forces. The questionnaire consisted of five parts: general information, educational, industrial, licensure and economic. A preliminary report of the results of the first 927 returned questionnaires was published in the JOURNAL, June 24, 1944, page 558.

One thousand questionnaires were reviewed from an educational point of view. The questionnaires were mailed to every fifteenth name on an alphabetical list

of all officers on duty with the Army, Navy and Public Health Service in the belief that a fair sample was obtained. The number of returned questionnaires indicated that information was returned from nearly every area in the world to which our troops in numbers are on duty. As further replies are received they will be tabulated and additional reports made.

Questionnaires were divided into six groups for study on the basis of date of graduation from medical school. It was felt that dates of graduation would be a better index than age of medical officers in the determination of future medical education desired. In the original report the questionnaires were divided into four groups according to year of licensure; however, an additional breakdown into smaller groups, especially of the recent graduates, was believed to yield more profitable information. Group 1 consisted of those graduated from 1941 to 1943 inclusive. Group 2 included the graduates of 1938 to 1940 inclusive, and group 3 the graduates of 1935 to 1937. In the original report group 1 consisted of those who were licensed in 1937 to 1943. Group

4 consisted of those graduated in 1930 to 1934 inclusive; group 5, 1920 to 1929, and group 6, those graduated prior to 1920.

There was the following number of officers in each group:

Group No.	Years of Graduation	Desire No Educational Courses	Desire 6 Months of Unspecified Period	Desire More Than 6 Months' Training	Total	Per Cent
1	1941-1943	4	41	119	164	16
2	1938-1940	21	38	148	207	21
3	1935-1937	39	82	69	190	19
4	1930-1934	63	79	50	222	22
5	1920-1929	60	82	38	180	18
6	Before 1920	17	16	4	37	4
Total.....		204	338	458	1,000	100

NOTE.—This table refers to number of officers and not to number of courses. All the following tables give the number of courses and not the number of officers.

Questionnaires were carefully analyzed in an effort to obtain as much information as possible concerning future medical educational plans. Many men requested courses in several subjects. Each request for a specific course of instruction was tabulated except when a request was made for more than three different subjects in a short period of time. The latter were entered as requests for general courses. All requests for refresher, "brush-up" and review courses or "visiting clinics" were also tabulated as general courses.

Educational requests were made for varying periods of time. A specific request, such as three months or two years, was easily tabulated. An average was used when requests were for two periods. For example, requests for six to twelve months or one to three years were counted as one nine month course and one two year course respectively. Also some men requested short six month review courses in addition to more definitive courses of several years' duration, and both requests were counted. Consequently there were more requests for courses than officers in some groups.

Each group was subdivided into three sections depending on the amount of training that was requested:

(a) No further training: Officers who desired no future training or who failed to answer that part of their questionnaire were considered as one section.

(b) Review courses: Men who requested a specified time up to six months were considered as those desiring review courses and were thus classified. In addition, men who did not give a definite time of training and from whose questionnaires it appeared they desired a short future course were also grouped as requests for review courses.

(c) House officerships: The third section comprised those men who expressed a desire for definitive training of more than six months that could be considered as residency or fellowship training. Questionnaires from men whose residency was interrupted by an early call to military duty and who requested "time enough for completion of board" were marked as requests for one or more years of study, depending on the amount of residency.

A detailed analysis of the six groups showed the following significant results:

GROUP 1 (GRADUATES OF 1941 TO 1943)

Almost all recent graduates came directly from their hospital training into the armed forces. There were only four questionnaires with the educational section

unmarked submitted by men who came directly from internship. The remainder desired additional training.

Men Who Want Six Months or Less of Future Education.—More than one quarter of the graduates of 1941 to 1943 inclusive desired a future training course of six months or less. There were 32 who came directly from internship and 8 who came from a residency. In many instances the residency was interrupted before its normal completion. There were 6 requests for three month training courses and 23 for six month courses. Thirteen men made 26 requests for short courses but did not specify the time they desired to utilize for educational purposes. The following number of requests were made for courses in the following specialties:

Pediatrics.....	2		
Psychiatry and neurology....	2		1
Orthopedic surgery.....	1		2
Radiology.....	1	Surgery.....	10
Obstetrics and gynecology....	2	Anesthesiology.....	1
Internal medicine.....	11	Neurologic surgery.....	1
		General.....	21

Many men failed to answer the questions concerning the location at which they desired their future training. About one third, or 15, did not give the name of an institution. Training was desired by the remainder at either specific locations, such as hospitals or medical centers, or geographic areas, such as cities or states. The following number of cities or locations were requested:

Boston.....	4	Philadelphia.....	1
Chicago.....	4	Baltimore.....	1
New Orleans.....	4	Ann Arbor, Mich.....	1
New York.....	2	Rochester, Minn.....	1
California.....	2	St. Louis.....	1

Men Who Want More Than Six Months of Future Training.—More than two thirds of the recent graduates in group 1 desired quite extensive educational courses. There was a total of 119 men, of whom 99 entered the armed forces directly after internship. There were 16 who came from a residency, many of whom had their training interrupted. Only 1 of the section came from general practice and 1 from special practice.

There were 29 requests for a one year course of study, 55 requests for a two year course of study and 57 requests for three or more years of study. In addition there were 3 requests for a short six month refresher course by men who wanted either a two or a three year course in some definite specialty. There were no requests for a nine month course of study. The following number of requests were made for the following specialties:

Pediatrics.....	5	Pathology.....	2
Psychiatry and neurology....	4	Ophthalmology.....	1
Orthopedic surgery.....	3	Otolaryngology.....	3
Dermatology and syphilology	1	Surgery.....	32
Radiology.....	1	Anesthesiology.....	1
Urology.....	4	Neurologic surgery.....	3
Obstetrics and gynecology....	20	General.....	11
Internal medicine.....	28		

Many men failed to answer the question concerning the institution at which they desired their training, and others named several institutions. An institution was not named in 31 questionnaires. The remaining number of men furnished at least 2 or more requests for the following cities or locations:

Boston.....	14	Philadelphia.....	4
Rochester, Minn.....	9	New York.....	3
Chicago.....	8	Baltimore.....	2
Ann Arbor, Mich.....	6	California.....	4
Ohio.....	6	New Orleans.....	2
St. Louis.....	6	Washington, D. C.....	2
Minneapolis.....	4		

GROUP 2 (GRADUATES OF 1938 TO 1940 INCLUSIVE)

Medical Officers Who Do Not Desire Any Additional Training.—A small group, or 21 medical officers, failed to indicate any desire for additional training. Seven of the men definitely marked their questionnaires that they did not desire further medical education, and 14 left that part of their questionnaires blank. Most of the men came from hospital service or practice. There were 2 who had left internships and seven residencies to enter the service. About one half of the men, or 11, were actually engaged in some practice, such as 6 in special practice, 3 held full time positions and 2 were in general practice. The American board had certified 3 of the men in special practice and 2 had received partial certification.

Men Who Want Six Months or Less of Future Education.—A total of 38 medical officers comprise the section of men in this category. About one third of them had left their hospital training period for duty with the armed forces. Two came into the Army after internship and 8 into the service directly after residency. Seventeen men were in general practice prior to their military service, and 9 were in specialty practice, of whom 3 were certified specialists. One man held a full time position.

Most of the men desired a review course of three to six months' duration. There were 18 requests for three month training courses, 21 for a six month training course, 4 for a two month training course and none desired a one month training course. The period of training was not specified on 16 questionnaires. Courses were selected in the following subjects:

Pediatrics.....	1	Orthopedic surgery.....	1
Radiology.....	1	Otolaryngology.....	1
Psychiatry and neurology.....	3	Surgery.....	10
Obstetrics and gynecology.....	10	Anesthesiology.....	1
Internal medicine.....	11	General.....	20

The institution at which training was desired was not mentioned by 18 medical officers. There were requests that training be given in the following communities by the following number of men:

California.....	3	New York.....	1
Chicago.....	3	Baltimore.....	1
Boston.....	2	Washington.....	1
Vermont.....	2	Tennessee.....	1
Pennsylvania.....	2		

Men Who Want More Than Six Months of Future Education.—About two thirds of the graduates of 1938 to 1940 inclusive desired definite future educational training courses. There were 148 medical officers in the section who wanted six months or more of training. About one half of the men came into the service directly after internship (32) or residency (40). Men who came from practice were in general practice (26), special practice (16) or full time medical practice (11). Requests came from 148 medical officers: 5 for nine month courses, 67 for one year courses, 56 for two year courses and 39 for three year courses or more. Only 2 of the section had American board certification and 5 had partially completed requirements. The following number of requests were made in the following courses:

Pediatrics.....	9	Pathology.....	5
Psychiatry and neurology.....	6	Ophthalmology.....	3
Orthopedic surgery.....	6	Otolaryngology.....	4
Dermatology and syphilology	1	Surgery.....	53
Radiology.....	4	Public health.....	1
Urology.....	2	Anesthesiology.....	3
Obstetrics and gynecology.....	27	General.....	12
Internal medicine.....	31		

About one third of the men failed to indicate an institution at which they desired their postgraduate training. Requests for courses by at least 2 men were given for the following locations:

Chicago.....	19	Philadelphia.....	5
New York.....	19	St. Louis.....	4
Boston.....	15	Minneapolis.....	4
Rochester, Minn.....	14	Iowa City.....	4
Ohio.....	7	Ann Arbor, Mich.....	3
California.....	6	Baltimore.....	2
New Orleans.....	5		

GROUP 3 (GRADUATES OF 1935 TO 1937 INCLUSIVE)

There were 39 officers who either did not desire additional medical educational training or who left their questionnaires concerning future plans blank. Most of the men, 21 medical officers, were in special practice before they entered duty and 5 were in general practice. Seven of the group held full time positions before entering military service. About one fourth of the section, or 10, were certified by an American board, and 2 others of the section had been partially certified. It appears that the latter could qualify for certification by a return to their civilian practice.

Medical Officers Who Desire Six Months or Less of Future Education.—A group of 82 medical officers signified that they desired some future medical educational training either of six months or of an undetermined period of time. About half of the section were in general practice (40) and the others in special practice (33) before they entered military service. Full time positions were occupied by 6 of the section, of whom 2 were medical teachers in medical schools. About one fourth of the entire section, or half of those engaged in special practice, had been certified by an American board. One medical officer was in the process of certification. Short refresher medical courses were desired by a majority of the men. Requests varied, 12 wanting a one month course, 7 a two month course, 26 a three month course, 52 a six month course and 19 an unspecified time. Requests were made for courses in the following specialties:

Pediatrics.....	5	Pathology.....	2
Psychiatry and neurology.....	4	Ophthalmology.....	6
Orthopedic surgery.....	3	Otolaryngology.....	3
Dermatology.....	1	Surgery.....	18
Urology.....	1	Anesthesiology.....	3
Obstetrics and gynecology.....	23	General.....	18
Internal medicine.....	29		

A variety of answers followed the location at which instruction was to be given. Requests varied from specific institutions, such as the Massachusetts General Hospital, the Presbyterian Hospital of Chicago and University of Minnesota, to cities and to general geographic locations, such as a Midwestern or Eastern city. The following centers were chosen by 2 or more men as being the most helpful in arranging for suitable postgraduate refresher courses:

Boston.....	11	Baltimore.....	3
New York City.....	8	California.....	3
Chicago.....	7	St. Louis.....	2
Philadelphia.....	5	Cincinnati.....	2
Rochester, Minn.....	3	Minneapolis.....	2

Medical Officers Who Want More Than Six Months of Future Training.—A section of 69 medical officers in group 3 expressed a desire to have longer periods of study than refresher courses. In the main the requests were for residencies or hospital fellowships. A few of them signified the desire of one year senior internships to be followed by suitable residency and then a specialty. A great number of these men were

in general practice (38) before entering the armed forces. There were 18 in special practice, of whom 8 had been certified by the American board and one was in the process of certification. Full time appointments were held by 12 of the section. A definite residency or fellowship was desired by 36 for one year, by 24 for two years and by 8 for three years, and 4 requested nine month courses.

The courses of instruction included:

Pediatrics.....	1	Ophthalmology.....	6
Psychiatry and neurology.....	3	Otolaryngology.....	4
Orthopedic surgery.....	3	Surgery.....	17
Radiology.....	4	Public health.....	1
Urology.....	3	Anesthesiology.....	2
Obstetrics and gynecology.....	5	Neurologic surgery.....	1
Internal medicine.....	11	General.....	9
Pathology.....	2		

Institutions were grouped in various centers in the tabulation of requests of medical officers. There were the following requests for the specific locations:

Philadelphia.....	13	Rochester, Minn.....	4
New York.....	9	New Orleans.....	3
Boston.....	8	St. Louis.....	3
Chicago.....	7	Minneapolis.....	2
Baltimore.....	5	Pittsburgh.....	2
California.....	5		

GROUP 4 (GRADUATES OF 1930 TO 1934 INCLUSIVE)

The graduates from medical schools during the years 1930 to 1934 inclusive were studied as a group.

Men Who Do Not Desire Any Future Medical Training.—There were 63 officers who did not desire any additional training. There were 43 men engaged in special practice before they entered active duty and 13 in general practice. Full time medical practice on a salary basis was indicated by 4 of this section. About two thirds of those in special practice were certified by an American board, or 29 officers. It was not surprising that this section of men do not desire any additional training, since more than three fourths of them indicated a strong desire for an early return to private practice.

Men Who Desired Six Months or Less of Future Education.—A group of 79 officers comprised this second section, of whom 35 indicated a training period of three months or less. The section was about equally divided between general practitioners (32) and specialists (35) prior to their entries into military service. Over one half of the latter, or 19, were certified by an American board. One officer held a full time salaried position. There were 11 requests for one month training periods, 8 for two month training periods, 28 for three month training periods and 46 for six month training periods. Seventeen requests did not specify the length of course. Postwar training was indicated in the following specialties:

Pediatrics.....	2	Pathology.....	1
Psychiatry and neurology.....	3		6
Orthopedic surgery.....	2		1
Dermatology and syphilology.....	1	Surgery.....	20
Radiology.....	4	Public health.....	1
Urology.....	2	Neurologic surgery.....	2
Obstetrics and gynecology.....	15	General.....	30
Internal medicine.....	17		

The name of the institution was not mentioned in about one half of the instances, or in 37 questionnaires. The following localities or cities were requested most frequently:

New York.....	11	Rochester, Minn.....	3
Chicago.....	4	Ann Arbor, Mich.....	2
New Orleans.....	4	Baltimore.....	2
Boston.....	3	Minneapolis.....	2
Philadelphia.....	3		

Men Who Want More Than Six Months of Future Training.—A total of 80 officers requested additional training in excess of six months. There were 43 in general practice and 33 in specialty practice. Of those in special practice, 14 were certified by an American board. There were 4 who held full time appointments, 1 of whom was a hospital administrator.

The amount of time that 17 requested was nine months, 48 one year, 23 two years and 5 three years.

The courses desired were as follows:

Pediatrics.....	1	Internal medicine.....	9
Psychiatry and neurology.....	4	Ophthalmology.....	11
Orthopedic surgery.....	2	Otolaryngology.....	13
Dermatology and syphilology.....	1	Surgery.....	23
Radiology.....	3	Plastic surgery.....	1
Urology.....	3	Hospital administration.....	1
Obstetrics and gynecology.....	7	General.....	11

The institutions at which training was desired was not mentioned in 28 cases. The following cities were named at which training was desired:

New York.....	14	Baltimore.....	3
Philadelphia.....	12	New Orleans.....	3
Boston.....	10	Ann Arbor, Mich.....	2
Chicago.....	7	St. Louis.....	2
Rochester, Minn.....	6		

GROUP 5 (GRADUATES OF 1920 TO 1929 INCLUSIVE)

Men Not Interested in Additional Educational Training.—An analysis of 60 men in group 5 who were not desirous of having additional training or undecided in the matter was undertaken. Thirteen of the section were in general practice, 2 held full time positions and the remainder (45) were in specialty practice. An analysis of the 36 men in the section who have specialty board certification and want no further education shows that most of them plan to reengage in private practice in their previous locality.

Men Who Desire Six Months or Less of Future Education.—A future educational program of six months or less was selected by 82 men in the section. Graduates of 1925 or later represented a majority of the section. Requests indicated that 9 desired a one month training course, 5 a two month course, 27 a three month course and 31 a six month course. There were 21 requests for courses of unspecified time. Forty-five of the section had previously been in specialty practice, of whom 18 were certified by American boards and 27 were in general practice. All requests indicated a type of review of refresher course. Future training was requested in the following specialties:

Pediatrics.....	5	Ophthalmology.....	5
Psychiatry and neurology.....	1	Otolaryngology.....	1
Dermatology and syphilology.....	5	Surgery.....	21
Radiology.....	2	Public health.....	1
Obstetrics and gynecology.....	6	Anesthesiology.....	1
Internal medicine.....	26	Neurologic surgery.....	1
Pathology.....	1	General.....	8

Training was desired at either specific institutions such as hospitals or medical centers, or geographic areas such as large Eastern cities and Midwestern cities, and followed closely that reported by previous groups.

Men Who Want More Than Six Months of Future Training.—There were 38 in this section, of whom about three fourths graduated after 1925. Eleven had been in general practice before their entry into the armed services and 15 mentioned specialty practice. A nine month course was indicated by 9, one year's training by 25, two years by 6 and three years by 1 officer.

The following specialties were selected:

Pediatrics.....	2	Pathology.....	1
Psychiatry and neurology....	3	Ophthalmology.....	1
Orthopedic surgery.....	1	Otolaryngology.....	3
Dermatology and syphilology	1	Surgery.....	7
Radiology.....	1	Public health.....	1
Urology.....	1	Hospital administration.....	1
Obstetrics and gynecology....	3	General.....	7
Internal medicine.....	8		

The training was desired in a wide variety of institutions located as follows:

New York.....	7	Boston.....	4
Chicago.....	5	California.....	4
Rochester, Minn.....	5	Ann Arbor, Mich.....	3
Philadelphia.....	5	New Orleans.....	3

The institution at which training was desired was either left blank or marked with a question mark on 24 questionnaires.

GROUP 6 (GRADUATES PRIOR TO 1920)

The oldest and smallest group consisted of 37 officers, 17 of whom did not desire any additional training or left the educational portion of their questionnaire blank. There were 16 men who requested 19 courses of six months or less, among whom 6 specifically asked for general courses. Requests were made as follows:

Pediatrics.....	1	Surgery.....	4
Psychiatry and neurology....	1	Hospital administration.....	1
Dermatology and syphilology	1	General.....	6
Internal medicine.....	5		

Four officers requested one year courses. Two requested courses in surgery, 1 in pathology and 1 a general course.

The following table summarizes the requests for educational courses by subjects for all six groups:

	Short Courses (6 Months or Less)	Long Courses (More Than 6 Months)	Total Courses
Anesthesiology.....	6	6	12
Dermatology and syphilology	5	4	12
Hospital administration.....	1	2	3
Internal medicine.....	99	57	186
General medicine.....	103	51	154
Neurologic surgery.....	4	4	8
Obstetrics and gynecology....	56	62	118
Ophthalmology.....	17	25	42
Orthopedic surgery.....	7	17	24
Otolaryngology.....	14	27	41
Pathology.....	5	11	16
Pediatrics.....	16	18	34
Plastic surgery.....	0	1	1
Psychiatry and neurology....	17	20	37
Public health.....	2	3	5
Radiology.....	8	13	21
Surgery.....	86	154	240
Urology.....	3	13	16
Total.....	452	518	970

This report is based on early returns from a pilot questionnaire and should be considered a preliminary statement. As further replies are received, they will be analyzed and published.

EXPANDING FIELDS IN MEDICINE AND MEDICAL EDUCATION

Wartime experiences in medical care for the armed forces and for civilians have accentuated the growing importance of certain fields in medicine, including neuropsychiatry, public health, industrial health, physical medicine and tropical medicine. The place of these expanding fields of modern medicine in undergraduate and graduate medical education is discussed in the following papers:

NEUROPSYCHIATRY

Colonel William C. Menninger, M. C.

Director, Neuropsychiatry Division,
Office of the Surgeon General, U. S. Army

Psychiatry has reached another crossroad in its evolution. Whether it maneuvers its way through the traffic will depend not alone on psychiatrists but on all organized medicine. It is no mere figure of speech to say that we are experiencing a worldwide psychosis. If we include in the concept of health the mental status of an individual, never in the world's history have we had such an unhealthy state. Just as the widespread serious epidemic of a serious disease commands the attention of all organized medicine, so should the present advanced mental disease of the world arrest the interest of all organized medicine. It should demand our attention to direct an attack on the causes, an understanding of the symptomatology, immediate measures of treatment and ultimately the prevention of a recurrence.

The war situation has developed the need for and the unlimited opportunities open to psychiatry. At every turn in the selection and training of our huge army, we are confronted with psychiatric problems. As we wage the war, more develop, and as our soldiers and sailors return, we shall meet still more. Already we have discovered acute needs for psychiatric knowledge

and practice. First, in our efforts to form this army we have observed at the selection level that there is an alarmingly high frequency of personality deviates in our civilian population, and a considerable number of men have been regarded as unfit to be fighting men in the Army. A second observation has been in our army hospitals, where we have had many psychiatric disorders, a majority of which are manifest as physical complaints. They are, in part, the result of the tough adjustment required plus the additional factor that a man in the Army does not have the opportunity or privilege of managing his life as he did as a civilian. In the Army, if he becomes distressed, whether it be overtly manifest in his emotions or disguised through his stomach, he becomes a patient in the hospital. A third observation has been the fact that combat conditions may make any normal man into a psychiatric casualty.

These observations and their implications in our large army confront us with the realization that the needs of psychiatry are greater than they have ever been. This does not necessarily mean that the incidence of psychiatric disorder is greater than it has been, but the job at hand compels us to face the situation and deal with it. On the other hand, many of these same borderline individuals in civilian life were not conspicuous. In many instances these problems were not assumed to be of medical concern. Because a man could apparently function in his civilian life, he did not demand our attention. We can be sure however that, like invisible taxes, this state of affairs cost us heavily. When we set about to form a fighting army we aggressively sought every man who could do a hard, exacting job—a job that required every man to be in first class condition. Then we subjected him to a task which in itself has proved that it can break the best integrated

individual. The total experience has forced us to become more acutely conscious of the psychiatric needs that obviously exist in our civilian population; our army hospital experience has forced on us in vivid fashion the recognition of the fluidity between the psyche and the soma when a man is placed under great pressure.

Psychiatric Manpower.—There are approximately 150,000 physicians in the United States. There are approximately 3,000 members of the American Psychiatric Association, which will include 90 per cent of the qualified men in this field. In the Army there is roughly 28 per cent of the membership of the American Psychiatric Association, with a considerable number of other medical officers less well trained and less experienced who nevertheless are functioning in the field of neuropsychiatry. Although no figures can be given, it is obvious that the number available is far out of proportion to the amount of work that needs to be done. As the Surgeon General, Norman T. Kirk,¹ has said, roughly 50 per cent of all civilian patients of all doctors are suffering from physical ailments growing out of emotional disturbances. Furthermore, psychiatrists belong to the scarcest category of medical specialists, both within the Army and in civilian life.

Obviously, there never will be enough psychiatrists if only specialists in this field attempt to deal with all psychiatric problems. The only solution lies in the better training and education of all physicians in the field of personality disorders, their recognition, their manifestations, their scientific treatment and their prevention. The distressing fact remains that, to date, the average physician is not equipped for this function. We see this manifested in both his attitude and his practice, and it makes little difference if our observation is made of the physician in civilian practice, in the army dispensary, in a gastrointestinal clinic, in the army hospital cardiovascular ward or in the private office. The attitude varies somewhat, depending on the physician's relationship to the patient, and there is considerable contrast in the environmental situation in civilian practice and in army practice. The attitudes assumed by the physician toward the neuropsychiatric patient are a direct reflection of his understanding and his skill in this field. Fortunately, many such patients receive excellent medical care. On the other hand, too often the patient with functional complaints is diagnosed only by the exclusion of organic difficulties. He is often subjected to indiscriminate and prolonged hospitalization with frequent laboratory testing and x-rays and occasionally he may even have an unnecessary operation or, if the operation is elective, he ends up in a worse state than before the operation. He may be treated with indifference or accused of malingering or given merely symptomatic treatment. Not infrequently he is told that nothing is the matter with him. Unfortunately, he is occasionally aggressively scolded or punished. It is an unpleasant fact for all of us in American medicine to face, and particularly medical educators, that the average physician does not understand or know how to treat minor (or major) personality disorders. He too often fails to recognize them as medical problems.

The obvious conclusion about this situation indicates, first, that the average physician has had insufficient training in our medical schools to understand the personality and its deviations. We have made great

strides in the improvement of our teaching of psychiatry in medical schools, as Ebaugh has outlined,² but it is still far short of the need.

Secondly, it must be assumed that there is an essential basic need that all physicians should know how to treat minor psychiatric problems. It is not presumed that they should or could handle major psychiatric problems any more than they may be expected to do major surgery. Their practices and attitudes, however, indicate without question that many are not competent to handle the minor psychiatry in their own practice.

Future Planning.—It is our experience as the direct result of the war, and more specifically our experience in the Army, that the physician, particularly the general practitioner of medicine, must have a more practical knowledge of psychiatry than he has heretofore received. This can be accomplished only through changes in our system of medical education. These changes must affect not only the educational plan for the medical student but also postgraduate education. The facts overwhelmingly point to the necessity of placing psychiatry as a basic medical subject. By so doing, this would not eliminate specialists of the field, as there is an urgent need for many more specialists. On the other hand, the universality of emotions, of feelings, and their effect on the human body make it imperative that every individual practicing medicine be as firmly grounded in the field as he is in the other basic medical subjects.

For the benefit of the great number of physicians now in practice, there is little doubt that many of them would welcome an opportunity for a short orientation course in psychiatry as related to general medicine and surgery. The experience in the Army undoubtedly will add very greatly to the number of men who desire such an opportunity. At present, very few opportunities for such training are available. Furthermore, it is highly desirable that such courses deal with the emotional factors in the general medical and surgical patients and with little or no attention paid to the problems of major psychiatry, particularly the psychoses.

The undergraduate course in psychiatry should be entirely overhauled with considerable less emphasis on the psychotic illnesses and much more emphasis placed on those fields of medicine and surgery in which the symptoms of functional illness are most frequently encountered. Our teaching methods of the past have all too often led the students to assume that psychiatry was only a specialty and they graduated failing to recognize that the knowledge and technics of this field would and should apply in every patient.

As medicine becomes more of a social science and involves the assistance of research workers, of laymen assistants, of nurses and for us in the Army, our tremendously important Medical Administrative Corps, we must recognize that these individuals should have a much closer contact in medicine from an earlier period in education than they do. In psychiatry it is highly important, whether we practice in an outpatient clinic or in a hospital, that we have the help of the clinical psychologist and of the psychiatric social worker. It is to be hoped that sometime our medical schools can become sufficiently universities to include in their training these intimate associates and assistants of the physician.

Not only should the course in psychiatry be greatly changed, but the whole medical course might very

1 Kirk, N. T.: Bull. U. S. Army M. Dept., July 1944, No. 78, p. 40.

2 Ebaugh, Franklin G., and Rymer, Charles C.: *Psychiatry and Medical Education*. Commonwealth Fund, 1942.

advisably point to a reorientation of the importance of the personality factors in disease. In every medical course we start the student in devoting hours, weeks and months in the dissection of the human body. We follow it with excellent courses in the physiology and the chemistry of this body. We are commendably grounded in the physical pathology of this body. Nevertheless we suffer in our system of medical education by so much emphasis on the material that the average medical student receives his diploma with only the vaguest conception that the most important part of his patient is the person who lives within the framework of the body. He leaves with slight, if any, idea that it is our ambitions and our strivings, our loves and our hates, our successes and our failures, our aggressivity and our passivity, that are probably the major determinants in the maintenance of health. This cannot be taught only in the course on psychiatry, it must be taught in medicine and in surgery and in every specialized field.

Last, but not least, is the opportunity, the responsibility of medical education to provide the leadership in reorientation regarding concepts of mental health. No field of medicine battles against such a welter of superstitions and misconceptions regarding its patients and its methods as does psychiatry. Unfortunately, our greatest lack of understanding and most frequent source of misunderstanding lies in the medical profession itself. Again, it may be in our system of medical education; it may be in the historical evolution of psychiatry from the period of werewolves and dungeons; it may be in the incomprehensible jargon of some psychiatrists; it may be, in part, the intangible nature of the subject in contrast to operative technics, stethoscopes and x-rays; it may be of a presumed necessity to defend our individual and naive belief that each of us is a "normal" personality; whatever the causes, the fact remains that the physicians' bungling of psychologic factors keep thousands of cults thriving. Because he is the physician, and thus the authoritative source of opinion for the layman, his attitude and understanding of psychiatry can and do color the public attitude. Even though progress has been made, the public conception is still a blurred picture of disgrace and fear, mysticism and self exemption. Is it too much to hope that the medical profession might take a more forceful initiative to gain enlightenment and disseminate it? It is fundamentally a challenge to medical education.

PUBLIC HEALTH

Dean A. Clark, M.D.

Senior Surgeon (R), U. S. Public Health Service

The field of public health, broadly considered, comprehends all health activities for which public responsibility has been assumed. Thus, it includes not only such traditional activities as sanitation and communicable disease control but also such functions as school health service, maternal and child health programs, medical care for the needy, care of the mentally ill and many services which are provided by other agencies, governmental or voluntary. Public action in the health field has been increasing at an accelerated rate in recent years, but medical education has by and large continued to prepare students for individual private practice with little regard for the changing scene. The greatest single problem now before our medical schools is to give their students new attitudes, information

and technics which increasing public action will demand of them.

In general, expansion in public health is taking two forms: first, growth in the number and size of the health services conducted or supervised by governmental agencies and in which both clinical and administrative positions await trained medical personnel; and, second, increased tax support for services which are largely provided by private practitioners and hospitals. An example of the first is the care of sick or disabled veterans in the facilities of the Veterans Administration and of merchant seamen by the Public Health Service, a vast enlargement of which is occasioned by the war. In the second group fall the Emergency Maternity and Infant Care program for the wives and infants of servicemen and the physical restoration of the civilian handicapped under the Barden-LaFollette act. Often, as in the care of the needy and medically needy, a combination of directly operated public hospitals and of tax payments to private sources is found.

There are numerous other instances of both types of public activity, some initiated during the war, others old and well established but stimulated to further growth by the emergency. All, however, will affect the future pattern of our health services. Of the older public programs, none is more significant or more generally accepted than the development of state and local public health services. Of the 3,070 counties of the United States, only about 1,800 have some form of full time health service. The House of Delegates of the American Medical Association, in company with many other groups, urged in 1942 the establishment of full time public health services throughout the country. In the past session, June 1944, the House again emphasized the need for expanding these services and for training qualified personnel. Health departments may be faced with increased responsibilities if tropical diseases are introduced into this country in serious proportions by returning servicemen.

The federal-state venereal disease control program is another well established activity that has grown enormously with the war and with the advent of newer, more rapid methods of treatment. The venereal diseases may be virtually eradicated if the use of these new treatment methods is extended when peace comes. Governmental agencies have also long been active in industrial hygiene, workmen's compensation, dental hygiene, control of cancer and the care of crippled children. Industrial hygiene in particular has received emphasis in connection with war production, and more thought is being given to the desirability of greater public responsibility for treatment of industrial diseases in addition to the traditional responsibilities of research and prevention.

The experience of Selective Service and of the armed forces with psychoneurotic and other emotional disturbances furnishes a powerful impetus for advances in mental hygiene and psychiatric treatment. Already there is a vigorous voluntary movement for increasing research and training in this field, for enlarging the number and size and for improving the quality of our services and facilities for mental hygiene and psychiatry. There can be little doubt that important public action will follow.

The depression of the thirties brought virtually complete acceptance by the public and by the medical professions of governmental responsibility for the medical care of the needy and the medically needy. This function has venerable Anglo-Saxon tradition behind

it, but its systematic organization on a nationwide scale, with some (though limited) aid from federal funds, is quite different from the local "doctor to the poor" of the past. Much of the best of this work has been carried out by public welfare agencies, but these activities should nevertheless be included in any comprehensive definition of "public health."

Care for the inhabitants of rural areas is becoming recognized as a service which cannot be satisfactorily provided, in many instances, without government aid. The Farm Foundation, for example, has developed cooperative health and medical service in Nebraska, with state assistance. The nationwide efforts of the Farm Security Administration and the War Food Administration have attained notable success and have been marked by sustained cooperation from the practicing profession. Farm organizations have long indicated a desire to see such efforts enlarged in scope and amount.

Public responsibility, in addition to its older functions, has been accepted or is being seriously considered for a number of new activities. The most recent is the passage by Congress late in June of an act authorizing the appropriation annually of funds (\$10,000,000 in 1945) to be used by the Public Health Service in the control of tuberculosis, including grants-in-aid to the states and other political subdivisions. Recently a committee of distinguished cardiologists recommended a similar federal-state program for the control of rheumatic fever. The revelation of large numbers of preventable and curative defects in Selective Service registrants may well result in widespread strengthening of our school health services and in increased public responsibility for the early correction of defects found in school children.

A growth of official or tax supported programs for the control and treatment of noncommunicable diseases of major importance may also be expected. The reduction of communicable disease and the aging of the population have resulted in an increased amount of chronic illness and dependency. Public action has already been taken in some areas toward improving and enlarging facilities for the treatment of patients with chronic conditions, but the problem is nationwide and will be dealt with on a far wider scale than heretofore. It seems likely too that the benefits of physical medicine will be made more widely available through public action if the studies of the Baruch Committee indicate the need.

Finally, there is a rapidly growing public interest in organized methods for prevention and treatment of sickness of all types and paying for its costs. Most efforts in this field have been under voluntary or private auspices, but they are by their very nature community, rather than individual, activities. Indeed, the city governments of San Francisco and New York have already taken active steps to secure organized services for their employees. Whether or not governmental participation increases in developing group medical practice and insurance against the costs of sickness, the vigorous support of labor, industry, agriculture and many medical and hospital groups assures important future developments.

This list of public activities in health is impressive, yet it is far from complete. These activities are increasing in both scope and number. Some require physicians in public office, more require the time and effort of private practitioners in providing services. The problem facing medical education is to train physicians for

intelligent participation in public health activities. Up to now, doctors have been content to ignore these programs or to oppose them, or to consider the services they render under them as a kind of charity.

This is not only unrealistic, it is dangerous. Many public health programs fail to live up to the best in medicine because the best physicians fail to participate. The public demands expansion of these programs, nonetheless, and they will constitute an ever larger proportion of all medical work. If their standards are less than the best, they threaten all professional standards.

It is time that medical students learned the facts of life. They should be fully aware that public health, in the broadest sense, will occupy much of their time and effort, whatever they may choose to do. They should be stimulated to see these activities not as something to be avoided or as a threat to private practice but as an intrinsic and challenging part of their everyday work. They should realize that publicly sponsored health functions will demand and should be given the best of their skill and enthusiasm. Only if the new graduate comes out eager to join with the public in action for health can we hope for the kind of constructive action that will, for the future, guarantee high quality in medicine, professional and economic opportunity for physicians, and good health for the nation.

INDUSTRIAL HEALTH

Leverett D. Bristol, M.D.

Chairman, Committee on Education, Council on Industrial Health
American Medical Association

AND

Carl M. Peterson, M.D.

Secretary, Council on Industrial Health

Wage earners are numerically and economically the most important single constituent in our population. It follows that industrial health should be the most important element in the public health. The Council on Industrial Health believes that industry, regardless of size, should have certain health services available to it. These are defined as follows:

1. A competent physician who takes genuine interest in applying the principles of preventive medicine and hygiene to employed groups and who is willing to devote regular hours to such service in the working environment.
2. Industrial nurses with proper preparation, acting under the physician's immediate supervision or under standing orders developed by him or by the committee on industrial health of the county medical society.
3. Industrial hygiene service directed at improvement of working environment and control of all unhealthful exposures, to be provided by physicians and others with guidance and assistance from the specialized personnel in state and local bureaus of industrial hygiene.
4. A health program which should include:
 - (a) Prompt and dependable first aid, emergency and subsequent medical and surgical care for all industrially induced disability.
 - (b) Health conservation of employees through physical supervision and health education.
 - (c) Close correlation with family physicians and other community health agencies for early and proper management of nonoccupational sickness and injury.
 - (d) Good records of all causes of absence from work as a guide to the establishment of preventive measures.

Widespread application of these services, suitably adjusted to community medical and health facilities, would enhance the well-being of millions of workers

and contribute greatly to the productive capacity of the country.

If industrial health is to expand and improve according to this general pattern, support must be assured from several influential quarters. The war, by reason of its insatiable demands on industry and industrial manpower, has in fact enlarged our concept of the industrial physician's functions from practical necessity to limitless opportunity. There are signs that support will be continued and augmented in the postwar years from the following sources:

1. The government. Governmental interest is represented by an unbroken trend toward liberalized procedure, greater coverage and increased benefits under workmen's compensation and social security. Each year new sanitary, safety and health codes are developed for enforcement by federal, state and local agencies. Bureaus of industrial hygiene have steadily improved their facilities for investigation of working conditions and for consultation with management and physicians.

2. Management. The successful performance of existing industrial medical departments strongly suggests that an acceptable formula can be developed jointly by industry and medicine which will bring qualified physicians regularly and directly into the work place. Once agreed on, the value of the formula must be demonstrated to industry both small and large. To this educational service the trade associations and manufacturing and commercial groups are already committed. It is only under this kind of organization that individual physicians can bring to individual plants widespread application of the great store of clinical and technical information already available in sufficient quantity to make every occupation a safe and healthful one.

3. Labor. Industrial health is here to stay as a factor in collective bargaining. The appearance of health and safety clauses in employment contracts, its advocacy of health and hospital insurance coverage, participation in case finding surveys and willingness in certain areas to support its own industrial hygiene services are indications of labor's rapidly mounting interest.

4. Medicine. Initiative and guidance in this expanding field must be assumed by the medical profession if high standards of accomplishment and conduct are to prevail. Progress in this direction is being made. Nearly every sizable industrial community has a committee on industrial health in its medical society, all the members of which are prepared to cooperate with other community interests to improve industrial health. The specialty groups likewise are beginning to realize that help from them is essential if many unhealthful and unhygienic problems are to be solved, and that industry also offers unparalleled opportunities for clinical investigation and observation. These activities augment, of course, the services of individual physicians already employed full or part time in industry.

Educational Requirements.—These developments, representative of improved integration between medicine and other affected groups, must be accompanied by improved opportunities for training. It is still largely true, in spite of recent advances, that industrial medicine, hygiene and health administration are commonly taught without real insight into industry's and the workers' needs and their relation to medical and health facilities in the community at large. There is a tendency to resolve the whole problem of medical service in industry by regarding it as general practice in a

plant. Most experienced industrial physicians would disagree. Industry's paramount need for the prevention of injury and disease with the resultant details of medical and engineering control over the worker and his environment are the factors which distinguish industrial health from conventional medical practice. Much as industrial health owes to every other medical discipline, its real future lies in the domain of preventive medicine and public health. It is in this direction that its essential characteristics as a recognized specialty are likely to occur.

The appointment of a committee representing the Council on Industrial Health and the Council on Medical Education and Hospitals is a step in the direction of orderly definition of the problem and its practical solution. A beginning has already been made.¹ It is hoped that through this means:

1. Every medical graduate will obtain reasonable grounding in the fundamentals of industrial medicine and surgery, industrial hygiene and toxicology, and industrial health administration.

2. Every encouragement will be given to promote introductory, refresher and continuation courses for practicing physicians under sponsorship of medical societies and medical schools.

3. The value of industrial experience during the internship can be investigated.

4. A program of graduate training can be evolved in conformity with existing standards for certification, using the residency and fellowship methods which characterize extended study in other clinical fields.

5. Coordinated training of physicians and engineers for industrial health service can be developed, preferably in schools of public health or institutes of industrial health.

6. Standards for the training and employment of technical assistants can be elaborated.

Medicine has much to offer industry. Its opportunities should not be hampered by lack of imagination or leadership.

PHYSICAL MEDICINE

The timely and informative report on physical medicine by Frank H. Krusen, M.D., Director, Baruch Committee on Physical Medicine, appears on pages 1093 to 1097 of this issue as an integral part of the Educational Number. It will be included in the reprint edition.

TROPICAL MEDICINE

Commander Lowell T. Coggshall
Medical Corps, United States Naval Reserve

Since the onset of the present war there probably has been no phase of medical education which has expanded more than that of tropical diseases. In the years preceding Dec. 7, 1941 the teaching of tropical medicine was not one of major interest, although it was rapidly gaining in importance and recognition. Also little effort was being expended at that time to supply students with adequate knowledge or opportunities for investigation of tropical and parasitic diseases. There were a few fortunate medical schools with far sighted leaders who realized the necessity of developing this field, but in most places the burden was carried by the zoologist or the parasitologist or divided between many departments and attracted little interest except to those few, chiefly nonmedical, students who planned a career of teaching or research. By the time the medical student

1 Admission date may be changed (a) to Nov. 1, 1944, (b) to September 1, 1944, (c) to October 1, 1944, (d) indefinite, (e) tentative.
 2 Also September 1943 and March 1944. 3 Also December 1943 and March 1 44. 4 Also June 1943 and September 1 44.
 5 Also December 1943 and 1944.

In February the Army curtailed the A. S. T. P. and has since renegotiated its contracts with medical schools to provide 28 per cent instead of 55 per cent of 1945 entering classes.

This increases to 47 per cent the numbers which must be obtained from civilian sources.

In April the Selective Service system abolished further occupational deferments of premedical and medical students not enrolled in medical schools by July 1, 1944. To meet this deadline fifty-six medical and basic science schools admitted a total of 1,675 civilian students to the freshman class somewhat earlier than the normal admission date.

Only nine schools thought they might be able to fill 47 per cent of their freshman places from civilian sources with no Selective Service deferments. Fifty-seven schools estimated reductions of from 10 to over 40 per cent in freshmen enrolments. There was an average reduction of 23 per cent for the sixty-six schools venturing estimates. The remaining schools were unwilling or unable to estimate the reduction that will occur.

"2. Those who do not have a letter of acceptance to an accredited medical school, for entrance by Dec. 31, 1944. These men will be continued on active duty, and will not be eligible for ASTP medical training."

There will be no further new assignments to the premedical A. S. T. program. As a result medical schools will have to select 75 per cent of their 1946 freshmen from civilians. This is manifestly impossible, and it is probable that entering classes in 1946 will be approximately half filled unless the Enlisted Reserve Corps are reinstituted or Selective Service regulations changed.

No change is contemplated in the Navy V-12 premedical or medical programs, except that the Navy's quota of medical students may be increased from 25 per cent to 31 per cent.

Should no adjustment be made to correct the present situation, a considerable reduction of graduates after the war will ensue. Although schools will continue the accelerated program, they will probably admit classes only once annually instead of every nine months. This of itself will reduce the number of graduates from the

A final development has still further jeopardized medical education. The Army appropriation bill for the coming year, which was passed by Congress June 23, contains a provision which reads in part as follows:

Provided, That no appropriation contained in this Act shall be available for any expense incident to education of persons in medicine (including veterinary) or dentistry if any expense on account of this education in such subjects was not being defrayed out of appropriations for the military establishment for the fiscal year 1944 prior to June 7, 1944.

A release from the War Department dated Aug. 1, 1944 states the following regarding this provision:

"Those individuals now on active duty whose medical or premedical educational expenses were defrayed in whole or in part by the government under the ASTP program prior to June 7, 1944, will be continued in the medical program of the ASTP. Those on active duty whose medical or premedical training was not defrayed either in whole or in part under the ASTP program prior to June 7, 1944, and who for that reason cannot be continued in the training program, fall into two classes who will be disposed of as follows:

"1. Those who have letters of acceptance and who would have entered an accredited medical school by Dec. 31, 1944. An individual in this group may elect to be discharged from the Army shortly before the entrance date of the class for which he was accepted; or to be assigned to the Medical Department with no further ASTP medical training.

present annual average of 7,000 to 5,000. If classes can be only half filled, this number will be reduced to 2,500 graduates per year. Since 3,300 to 3,500

physicians die each year, there will result an annual and cumulative deficit of 1,000 doctors a year.

Still further reductions in graduates and permanent damage to the "plant" of medical education will result from some schools being forced to close their doors

effects of the accelerated program because of other important complicating variables, chief of which are the reduction in teaching staff, the many uncertainties in the minds of students and the admission of students every nine months, compelling depleted staffs to function almost continuously.

The accelerated program does not necessarily involve admissions every nine months. It can be conducted with annual admissions, as has been the case at the University of Michigan and the Woman's Medical College. Acceleration with annual admissions requires the admission of only the peacetime annual number of freshmen and produces only the prewar number of annual graduates. This plan also reduces the teaching load of the staff. If a school is on the quarter system, accelerating and admitting a new class every October, there will be no freshmen in school during the summer quarter, no sophomores in the spring, no juniors in the winter and no seniors in the autumn. It follows that a faculty member who teaches only freshmen will have no teaching duties in the summer. One who teaches only sophomores will be free from teaching in the spring, and so on. It would be highly desirable to continue the experiment of medical school acceleration under these somewhat more favorable conditions.

Many schools plan to return to annual admissions while still accelerating, commencing in the autumn of 1945. By that time a three year, four session cycle will have been completed, with the production of one extra class of graduates. The probable future shortage of qualified applicants has also influenced this contemplated change. Forty-five schools plan to return to annual admissions in 1945. Twenty-four schools are as yet uncertain of their plans; probably an appreciable number of these will also decide to change. Of the remaining eight schools, five now plan not to change, two have always had annual admissions and one will continue to admit classes quarterly.

In all Canadian schools acceleration has been discontinued. In most schools, this change became effective with the class entering in the autumn of 1943. Only upper classes, already embarked upon the program at that time, are continuing to accelerate. The reasons given for the return to the decelerated program are: 1, further additions to and replacements in the services will be adequately met under the new plan; 2, the 37 per cent depletion of the teaching staffs makes a continuation of acceleration difficult; 3, there was evidence of some deterioration of educational standards; and 4, there was evidence of deleterious effects on the health of students.

Seniors who commenced the accelerated program in July 1942 graduated in March 1943 and completed their nine month internship in December 1943. Several hundred of these are now in the armed forces. Without acceleration and the reduced internship they would not have become available for active military duty until July 1944.

Most schools graduated two classes during the calendar year 1943, about March and December. The former of these classes was reported on in the 1943 Educational Number. The current issue gives data (see "graduates," page 1119) on the latter class. Data on two additional classes will be available for the 1945 Educational Number. By that time four classes will have been graduated in three calendar years.

Between July 1, 1942, when acceleration started in most schools, and June 30, 1944 there were 10,357

medical graduates (see also table 14). Estimates of graduates in the ensuing eighteen months are shown in table 6. From July 1, 1944 to June 30, 1945 there will be approximately 9,844 graduates. The total graduates for the four session three year cycle is estimated at 20,201. This rate of production of physicians exceeds that at any previous times.

In table 7 are listed the estimated numbers of graduates from each medical school, by months, from July 1, 1944 to Dec. 31, 1945. This table will be particularly valuable to internship hospitals by providing information on the numbers of graduates from the various schools and the times they will become available for internships.

PREMEDICAL EDUCATION

The premedical Army Specialized Training and Navy V-12 programs meet the minimum admission requirements of all schools, in the cases of army and navy students assigned to medical schools. These programs also meet the minimum requirements for admission to an approved medical school as formulated by the Council on Medical Education and Hospitals.

Most schools desire also to publish admission requirements in terms of academic years or semester hours for civilian applicants. In tables 9 and 10 (pages 1116, 1117 and 1118) are given the civilian premedical requirements for each medical school in the United States and Canada. In 1945, 4 schools will require a degree or four years, 30 will require three years, 5 require two to three years, 45 only two years and (3) (Canadian) schools will admit students with one year of premedical work. As compared with the current year, in 1945 there will be 7 more schools requiring three years of premedical work, and 7 less that will accept two years or two to three years.

Deans have now had experience with selections of students for the A. S. T. and V-12 programs and are in a position to estimate the quality of medical students who will enter the study of medicine under these programs. Deans tend to be somewhat pessimistic. About one third (26) of the 72 deans expressing an opinion think that the quality of freshmen will be poorer than

very few or none of the entering freshmen would have been unable to obtain their premedical training without army and navy financial support. Thirty deans thought that 5 to 55 per cent of army and navy premedical students would have been unable to go to college as civilians paying their own way. The average for the thirty estimates was 21 per cent.

formerly. About one half (34) think the students will be of about the same quality as before the war. Only one sixth (12) think incoming students will be better.

Since the ability to pay for a medical education is not a factor in the selection of men for premedical training under the army and navy program, it becomes important to know whether significant numbers of qualified men might now be enabled to enter medicine who could not do so formerly for financial reasons. Seventeen deans were unwilling or unable to express an opinion on this question. Twenty-nine thought that

It seems clear that no careful study of this problem has been made and the estimates cited are opinions. The real facts would be difficult to unearth.

LICENSURE UNDER THE ACCELERATED MEDICAL
SCHOOL PROGRAM, THE PREMEDICAL A. S. T.
AND NAVY V-12 PROGRAMS, AND THE
NINE MONTH INTERNSHIP

All states in the Union, as well as the District of Columbia, Alaska, Hawaii and Puerto Rico, have made certain adjustments in their licensure legislation or

practices, where such were required, to facilitate the licensure of graduates under the accelerated program, at least for the duration of the war. It now appears that these adjustments in certain states may not adequately meet the needs of those students who may spend a week or two less than thirty-six months in medical school. Such students are typical, because those starting school July 1, 1942, for example, are likely to graduate a week or so prior to July 1, 1945. Legislation in four states is such as might not provide for these students.

In Illinois the amended law reads ". . . the time elapsing between the beginning of the first year and the ending of the fourth year . . . (as regards) . . . students matriculating or entering upon such medical course during the years 1942, 1943 and 1944 . . . shall be not less than thirty-six months. . . ." A literal interpretation of this legislation would seem to bar the typical students, as well as students who may have entered the accelerated program in 1941 or will enter it in 1945 or later

TABLE 8—*Relationship of the Nine Month Internship to Licensure in All States Requiring an Internship*

Accepted as Fulfilling Internship Requirement	Additional Three Months in Civilian Hospital or Military Service Required	
	Will Give Examination at End of Nine Months	Will Not Give Examination Until Completion of Year's Service
Alaska	Alabama ¹	Illinois ²
Delaware	District of Columbia ¹	New Hampshire
Idaho	Iowa ¹	New Mexico
Michigan ¹	New Jersey ¹	
Montana ¹	North Dakota	
Nevada	Oklahoma ¹	
Pennsylvania ¹	Oregon ¹	
West Virginia	Puerto Rico	
Wyoming	Rhode Island ¹	
	South Dakota ¹	
	Utah ^{1,2}	
	Vermont ¹	
	Washington ¹	
	Wisconsin	

Hawaii, which requires an internship for licensure, has not reported on the relationship of this requirement to the shortened internship.

Some states require the internship of graduates of medical faculties abroad and reciprocity or endorsement applicants.

¹ Will also give examination on completion of the medical course but withhold license until internship is completed.

² Military medical service must be in a military hospital.

In the District of Columbia the law specifies "four graded courses of not less than nine months each." Under a literal interpretation of this law also, students finishing in thirty-five and a fraction months might encounter difficulties.

The Georgia law requiring forty-two months to elapse "between the beginning of the student's first course of medical lectures and the date of his graduation" has not been amended. However, the Georgia Board of Medical Examiners has advised in effect that graduates of accelerated medical courses could qualify for licensure.

The Minnesota law provides for "four entire sessions of not less than thirty-six weeks each." Difficulties may occur under this law, since it calls for 144 weeks of medical work. The thirty-five plus months of a typical curriculum includes 152 plus weeks. Vacation periods are thereby limited to a total of eight weeks during the three year course.

The information received from those states whose licensure laws include specific premedical requirements seems to indicate that there should be no licensure difficulties encountered by students whose premedical work was taken under the A. S. T. or the Navy V-12 or comparably accelerated civilian programs.

For those states requiring an internship, table 8 indicates the status of licensure legislation as regards the nine month internship. At least for the duration of the war eight states and Alaska will accept a nine month internship as fulfilling the internship requirement. Twelve states, the District of Columbia and Puerto Rico require an additional three months in a civilian hospital or military service and will withhold the license until this is completed but will permit applicants for licensure to write the examination on completion of the nine month internship. In three states physicians are not eligible to take the examination until after completion of a year's internship, three months of which may be in the military service. Officers seeking licenses in these three states must delay licensure until after the war or seek furloughs to take the examinations. In the past it has been possible for officers to obtain furloughs for this purpose. Four states specifically require the military medical service to be in a military hospital.

FACULTY MEMBERS IN WAR SERVICES

On July 1, 1944 the 77 medical schools and schools of basic medical sciences in the United States had contributed a total of 5,828 of its faculty members to the armed forces. This number is somewhat larger than the 5,637 of last year and is still in excess of 10 per cent of the medical officers in the armed forces. It seems apparent that medical schools have contributed approximately as large a proportion of their faculties to the armed forces as the proportion of physicians not engaged in academic work who have been commissioned.

This depletion of faculties continues to handicap the teaching of more medical students and in less time than in normal years. Further faculty reductions have resulted from increasing participation in war research and special war assignments. As contrasted with 130 civilian faculty members engaged in full time war work a year ago, there are now 211 so employed, from 23 medical schools in the United States.

This relatively small figure represents serious losses in teaching staff in some critical areas, since practically all these men were recruited from the full time faculty members mainly in the basic sciences. Furthermore, this figure includes only those on full time war research. The total loss in teaching manpower is much greater, since even larger numbers of teachers are devoting a considerable part, but not all, of their time to war research.

From the 10 schools in Canada, 265 faculty members are in military service and 18 are engaged in full time war work.

The loyalty and devotion of faculty members remaining to carry on the increased work of the medical schools under adverse conditions is to be highly commended. In the demobilization period, special consideration should be given to the preferential early release of physicians on medical school faculties, to restore the quality of medical instruction to a higher level as soon as possible.

DEVELOPMENTS IN MEDICAL EDUCATION

During the past year the Medical School of the Southwestern Medical Foundation, located at Dallas, Texas, has been added by the Council to the list of approved medical schools. Dr. Tinsley Harrison is dean of the faculties and Dr. Donald Slaughter is dean

Statistics of approved schools of the basic medical sciences will be found in table 10, page 1118.

* These premedical requirements apply to civilian applicants in most instances. All schools in the United States will consider completion of the Army or Navy premedical program, by male applicants on active duty, as fulfilling academic admission requirements.
† Fifth year (internship) enrolment not included in total column.
‡ Sixth year enrolment: Alberta 37; Queens 46; Western Ontario 37; Toronto 106.
• For Army and Navy; all others degree required.

of students. The Bowman Gray School of Medicine, at Winston-Salem, N. C., has expanded from a school of the basic medical sciences to a four year medical school. Its first class graduated in December 1943. The University of Utah School of Medicine, at Salt Lake City, has also developed a four year program and graduates its first class in September 1944. Both Bowman Gray and Utah have been added to the Council's approved list, which increases the number of approved medical schools in the United States to 69.

There remain 8 schools of the basic medical sciences. The University of Alabama has virtually completed plans for expansion to the four year status, employing the clinical facilities of Hillman and Jefferson hospitals in Birmingham. One city block adjacent to the hospitals has been given to the university. One million dollars has been appropriated for the construction and equipment of basic science laboratories on this site after the war. Until then, Dr. Stuart Graves will continue as dean of the Basic Science School at Tuscaloosa. Dr. Roy R. Kracke is in charge at Birmingham. It is

APPROVED MEDICAL SCHOOLS

Medical schools and schools of the basic medical sciences in the United States and Canada approved by the Council on Medical Education and Hospitals of the American Medical Association for the academic session 1943-1944 are listed in tables 9 and 10, pages 1116, 1117 and 1118. The tables include quantitative premedical requirements for applicants not in the A. S. T. P. or V-12 premedical programs. The enrollment by classes, including fifth year students interning or engaged in research, and the total attendance, which does not include fifth year students, apply to the first academic year beginning 1943. The number of graduates from July 1, 1943 to June 30, 1944 is listed. The name of the dean or acting dean is also given. Figures for the sixth year enrollment in Canadian schools are given in a footnote.

The probationary status of the University of Arkansas and the University of Texas has been removed by the Council, so that at present no four year schools of

* On probation.

These premedical requirements apply to civilian applicants in most instances. All schools in the United States will consider completion of the Army or Navy premedical program, by male applicants on active duty, as fulfilling academic admission requirements.

hoped that junior instruction will commence in Birmingham by July 1945.

At least 3 of the remaining basic science schools are seriously considering developing the full four years. This trend in the basic science schools may be ascribed to three major factors: (1) the increasing difficulty encountered by students in these schools to obtain admission to junior classes in other schools, (2) the closer integration of basic science and clinical work in medical education, requiring availability of clinical facilities for sophomore and even freshman work, and (3) the desire of states to increase the proportion of medical students in state schools who will remain in the state to practice medicine.

The war has accentuated the maldistribution of physicians to urban and rural communities. Several states are contemplating the formation of new medical schools "to provide doctors for rural communities." But there is no assurance that more doctors will practice in small towns if more doctors are produced. The production and the distribution of doctors are independent. The mere production of more doctors is more likely to produce overcrowding of physicians in large cities than to fill the unmet needs in rural areas.

medicine are on probation. Two schools of the basic medical sciences remain on probation.

The fifth or intern year is now required for the M.D. degree by only 5 schools in the United States: College of Medical Evangelists, Southern California, Stanford, Northwestern and Minnesota.

General historical information regarding all institutions on the approved list maintained by the Council appears on pages 1134 to 1142.

ENROLLMENTS

Enrollment figures by classes for the first session beginning in 1943 are given in tables 9 and 10 and recapitulated in table 11. In the 77 schools in the United States there were 23,529 students studying medicine (excluding the fifth year), which is an increase of 898, or 4.0 per cent, above the preceding academic session. In the Canadian schools there were 2,475 students (excluding the fifth and sixth years), an enrollment increase of 89 students, or 3.7 per cent. In addition there were 451 fifth or intern year students in schools in the United States plus 262 fifth year, 226 sixth year students and 150 interns in Canada.

In schools offering the complete four years of work, the 4 schools in the United States with the highest enrolments were Illinois 676, Northwestern 590, Jefferson 570 and Tennessee 565. Eleven schools had enrolments exceeding 500. The 3 with the lowest enrolments were Baylor 129, Woman's Medical College 140 and Vermont 142. Utah, with 126 students, had no fourth year class during the session for which these data are given. In Canada the highest enrolment occurred at Toronto with 772 students in the six years, and the lowest at Alberta with 151 students in its five year course.

Alabama was the only basic science school with more than 50 students in a class, that school enrolled 54 students in each of the two classes. The lowest enrolment (in the United States) occurred at South Dakota, with 26 freshmen and 18 sophomores.

In table 12 are given the enrolments in the classes of the "present" academic session, which for most schools runs from about January to September 1944 and in all schools includes the month of May 1944.

TABLE 11—Total Enrolments by Classes in Medical Schools of the United States and Canada for the First Session Beginning in 1943, with Totals for Preceding and Following Academic Sessions. Students in the Intern Year Are Not Included

	Freshmen	Sophomores	Juniors	Seniors	Total	Total Preceding Session*	'Present' Session Including May 1944

* Academic session ending with admission of first class in 1944.

† The first four years in some Canadian schools do not correspond to those years in schools of the United States.

‡ Does not include 488 in fifth and sixth years.

For comparison with enrolments in the two preceding sessions, total figures are also given in the last column of table 11. In this session there were 23,782 students enrolled in the schools of the United States. This is a further increase of 253 students in excess of the preceding session. In the past three sessions enrolments have increased 27 per cent, 40 per cent and 11 per cent. Despite the low last overall increase, figures by classes for the past few sessions indicate that certain schools have increased the numbers in entering classes well beyond what is probably warranted.

This trend is evident in the figures of table 13, which gives the number of students enrolled in the four classes and in internships when required for graduation in medical schools of the United States, covering the past fourteen years. In each of the four medical school classes there were more students enrolled during the first academic session beginning in 1943 than at any previous time in the fourteen year period. Excluding the interns, enrolments have increased by 2,150, or 10 per cent, since the 1940-1941 academic session, although in some schools the increase has been considerably in excess of 10 per cent. The total enrol-

ments at the present time are higher than at any time since 1907, when there were 159 medical schools in existence.

Table 13 also shows the continuing decrease in numbers in the required intern year.

GRADUATES

Graduates from July 1, 1943 to June 30, 1944 are included in table 9, pages 1116 and 1117. In this period there were 5,134 graduates. The four schools graduating the most students were Illinois 161, Northwestern 161, Jefferson 133 and Harvard 132. The

smallest numbers were graduated from Baylor 16, Woman's Medical College 21 and Bowman Gray 27. From the 9 medical schools of Canada there were 523 graduates. The largest number, 107, graduated from Toronto and the smallest number, 31, received degrees from Western Ontario.

1943-1944.....	6,561	6,071	5,640	5,257	451	23,980

Table 14 gives the number of students and graduates for the past forty years. The effects of acceleration on numbers of graduates do not yet appear in these statistics because the latest figure consists mainly of those who graduated in December 1943. Most schools will graduate another class very soon after this Educational Number is published. In most schools there will have been two additional graduations (in about September 1944 and June 1945) before the appearance of the 1945 Educational Number. For further discussion of the effects of acceleration on numbers of graduates see "The Accelerated Program," page 1112.

GRADUATES BY STATES

The 77 schools in the United States are located in thirty-six states and the District of Columbia. The numbers of schools, students and graduates in these

* Includes figures for schools of the basic medical sciences.

states are shown in table 15. Each of six states enrolled over a thousand students in their schools. Students and graduates of the 29 schools of these states total more than 45 per cent of all students and graduates in the United States. In order, these states are

New York 9 schools, 3,008 students, 678 graduates; Pennsylvania 6 schools, 2,542 students, 597 graduates; Illinois 4 schools, 1,849 students, 464 graduates; Massachusetts 3 schools, 1,188 students, 276 graduates; California 4 schools, 1,097 students, 237 graduates, and Tennessee 3 schools, 1,021 students, 193 graduates.

Seven of the thirty-six states with schools had no graduates, since their schools did not offer the complete medical course. Twelve states had less than 100 graduates, the lowest being Vermont, with 33 graduates from its 1 medical school.

RESIDENCE OF STUDENTS

The permanent home residence of all students in medical schools of the United States and Canada during the first academic session commencing in 1943 is indicated in table 16, pages 1122 and 1123. It is felt that

* Excluding fifth or intern year students.

a tabulation of the permanent residence of students may give a better indication of the geographic source of medical students than would a tabulation of the birthplace, since many students may leave the state of their birth and become identified with another state through years of residence. On the other hand, it is recognized that the home residence at the time of admission to a medical school might have been of relatively recent origin in some cases.

Included in the table are 23,529 students in schools of the United States and 2,475 students in the first four years plus 488 fifth and sixth year students in Canada, totaling 26,492. Students in the intern year are not included.

Every state in the Union, including the District of Columbia, had 18 or more medical students in the schools listed. Residents of New York provided the greatest number of students, 2,881. Next in order are Pennsylvania 1,857, Illinois 1,384, Ohio 1,298 and California 1,162. These five states supply a total of 8,582 students, or nearly a third of the registration of

the 87 schools in the United States and Canada. However, these states provide facilities for the training of well over a third of all students of the United States and Canada, since 9,437 students were enrolled in the 26 schools in these five states.

Of the 2,963 students in Canadian schools in all six years 175, or 5.9 per cent, came from the United States. Most of these, 121, were enrolled at McGill, nearly a third of whose student body of 409 comes from the United States.

There were 197 students from the United States territories and possessions in 40 schools in the United States. None were enrolled in Canada.

Students from Canada numbered 2,745, of whom 2,708 were in the 10 Canadian schools and 37 in 9 schools in the United States. Twenty-four Canadians attended the College of Medical Evangelists, 5 the University of Minnesota. In none of the other 7 schools were there more than 2 Canadian students.

Foreign students numbered 260, of whom 180 attended 43 schools in the United States and 80 were enrolled in 6 Canadian schools. Schools enrolling the largest numbers of foreign students were the College of Medical Evangelists, 39, and Tulane, 21.

TABLE 17.—Enrolment of Students from States in Which There Are No Medical Schools

Wyoming.....	32	12	Colorado (7)
Total.....	2,054		

There are twelve states in the Union in which no medical schools are located. These states are listed in table 17, which also shows the number of students from each of these states enrolled in medical schools, as well as the number of schools to which these students went. There were 2,054 such students, over half of whom came from New Jersey and Washington. From New Jersey 858 students attended 58 medical schools. The greatest number, 97 students, attended New York University. From Washington there were 360 students in 41 schools; of these, 59 students attended Oregon and 59 Northwestern.

Table 18 gives the resident and nonresident enrolment in each of the 77 schools in the United States. More than one third of the students were enrolled in schools outside the state of their residence. The following 23 schools enrolled more nonresident students than students from the state in which the school is located:

Medical Evangelists	Tulane	Cornell
Yale	Johns Hopkins	Duke
Georgetown	Harvard	Hahnemann
George Washington	St. Louis	Woman's
Howard	Washington	Meharry
Northwestern	Vanderbilt	Vanderbilt
Chicago	Dartmouth	Marquette
Louisville	Columbia	

Only 4 schools admitted no students nonresident in the state: Georgia, Mississippi, Missouri and Texas.

REQUIRED INTERNSHIP

The medical schools requiring a hospital internship for the M.D. degree are shown in table 19. Six schools in the United States and 4 in Canada require an intern-

ship for graduation. No change in the list has occurred within the past year.

In the past year there were 451 students in the United States and 150 in Canada, a total of 600, reported as completing the fifth or intern year in fulfilment of the internship requirement for the M.D. degree.

[illegible]

Although relatively few schools require the internship for the M.D. degree, this is required for licensure by twenty-three states, the District of Columbia, Alaska, Hawaii and Puerto Rico. Table 8, page 1115, lists these states and indicates the relationship of this requirement to the nine month internship. In the past year New Mexico has added the internship requirement. Some states require the internship of graduates from schools abroad and applicants for reciprocity or endorsement. The licensing boards of Illinois, Michigan, North Dakota, Pennsylvania and Washington require the internship to be a rotating service, while New Jersey recommends this type of service.

A few of the medical schools and licensing boards maintain their own list of hospitals acceptable for intern training, but the list of approved internships compiled by the Council on Medical Education and Hospitals is generally used.

Government restrictions on the use of paper necessitated omission of the Councils list from the Educational Number of THE JOURNAL. However, copies of the revised list of hospitals approved for internships and residencies have been printed and will be sent to all approved medical schools, medical libraries, approved hospitals, state licensing bodies, specialty boards and other interested agencies. The list is also included in the reprint edition of the Educational Number.

DISTRIBUTION BY SEX

Students in the first academic session commencing in 1943 and graduates from July 1, 1943 to June 30, 1944 in the United States and Canada classified according to sex are shown in table 20. The enrolment was 25,113 men and 1,379 women. Graduates numbered 5,390 men and 267 women. All but 5 of the 87 schools reported women students. These schools regularly do not admit women. They are Georgetown, Harvard, St. Louis, Dartmouth and Jefferson. Emory and Queen's (Canada), which in the past did not admit women, now report 1 and 4 women students respectively.

Women students in the United States numbered 1,176 as compared with 22,353 men. In Canada there were 203 women and 2,760 men students. In the 1 medical college for women there were 140 students and 21 graduates. Nine schools, including 2 in Canada, enrolled more than 30 women. There were 74 at Toronto and 39 each at Illinois and at New York Medical College.

There were 267 women graduates from 66 of the 78 four year medical schools. In the United States there were 239 women graduates and 4,895 men. In Canada there were 28 women graduates and 495 men.

Table 21 shows the distribution of students and graduates by sex for a period of nine years. The percentages of women medical students and graduates in the United States since 1905 are shown in table 22. For the academic session commencing with the first class entering in 1943, the percentage enrolment (5.0

per cent) was somewhat less than in the preceding year (5.1 per cent), and the percentage of graduates (4.7 per cent) was somewhat higher than in the preceding year (4.6 per cent).

We may expect increases in the enrolment of women in the next entering classes, with the current limitations on the supply of qualified men. However, it is not apparent that there is a large reservoir of qualified women students interested in and prepared to study medicine. The ratio of women applicants to women accepted in medical schools has been about the same as the ratio for men. Should schools determine to admit a considerably larger proportion of women in the future, they would probably be unable to do so without accepting students with qualifications inferior to those required in the past from either men or women.

LOAN FUNDS AND SCHOLARSHIPS

Since over 85 per cent of the students in medical schools are now being financed under the Army and Navy programs, the need for student loans and scholarships has been greatly reduced. At the present time needy and deserving civilian students can probably be adequately provided for locally. In many instances university and college funds for these purposes have

TABLE 21.—Distribution by Sex in the United States and Canada, 1936-1944

Year	Students		Graduates	
	Male	Female	Male	Female
1935-1936.....	24,219	1,254	5,388	268

1943-1944.....	25,113	1,379	5,390	267

accumulated from lack of demand for them. Such funds should be carefully conserved, because of the likelihood that there will soon be a higher percentage of civilians in our medical schools. Since the accelerated program must be continued to fulfil Army and Navy agreements, financial hardships may be encountered by civilians. There may again occur the need for special sources of aid similar to that provided in the past by the generous grants of the W. K. Kellogg Foundation and by government loans.

PART TIME, SPECIAL AND GRADUATE STUDENTS

Students in these categories, shown in table 23, are included in none of the preceding tabulations. Part time students (72, in 18 schools of the United States and Canada) were about as many as a year ago, although that number represented a substantial decrease below peacetime numbers.

Special students include those carrying work in such fields as public health, physicians reviewing for specialty board examinations and students preparing to become physical therapists or laboratory technicians. Curriculums in these and other fields may involve some work in the medical school. There were 167 such students in this category reported from 30 schools during the academic session here reported. This compares with 190 in the preceding year and 416 in the year before that.

There were 211 students not candidates for the medical degree pursuing medical subjects in 16 medical

schools in the United States and Canada. The preceding year saw 434 such students enrolled. In general, these are graduate students seeking a higher degree other than the M.D.

The reduction in numbers of students in these groups is due to the war. We may look forward to the time

when graduate students taking medical courses will increase in numbers and when substantial numbers of qualified medical students will desire and be able to carry a part time medical course while working toward a higher degree in one of the biologic sciences.

GRADUATES WITH BACCALAUREATE DEGREES

At the present time no school in the United States requires a degree for admission. In Canada, Montreal and Laval have this requirement. In 1945 three schools (Vanderbilt, Montreal and Laval) will require a degree

from civilian applicants. Three schools (Kansas, Oregon and Dartmouth) required the student to earn a bachelor's degree during the first year in medical school. Yet 75 per cent of all the graduates from 77 four year schools in the United States and Canada also held baccalaureate degrees, as shown in table 24. This does not include those earning the B.S. in Medicine, who are presented in the next section.

In the United States 4,131 (or 80 per cent) of the 5,134 medical graduates also held bachelor's degrees, and in Canada 289 (or 55 per cent) of the 523 medical graduates also held the additional degree. All the graduates of the following eight schools held both degrees: Stanford, Yale, Johns Hopkins, Minnesota, Albany, Western Reserve, Oregon and Jefferson.

GRADUATES WITH THE B.S. IN MEDICINE

Certain graduates of 30 medical schools in the United States and of 3 of the medical schools in Canada received the Bachelor of Science degree in Medicine. There were 450 such degrees awarded in the United States and 7 in Canada, a total of 457. The largest single group to receive the degree were 87 graduates of the University of Illinois. Indiana awarded 64 and Cincinnati 41. Other schools granted fewer than 34 and 21 schools less than 10 each.

FEES

The eighty-seven medical and basic science schools in the United States and Canada have been arranged in five groups in table 25 according to the tuition fees charged resident students for the first academic session commencing in 1943. The data are based on the average tuition fee charged for the complete medical course and includes such minor charges as those for matriculation, breakage, diploma and graduation.

There is a continuous upward trend in tuition fees. No school now charges less than \$100 for the year. The average resident fees charged by medical schools in the United States in the past five years, ending with the first academic session starting in 1943, have been \$378, \$386, \$395, \$407 and \$409.

Thirty-four schools in the United States and 6 in Canada make an additional charge for nonresidents. The Army and Navy pay nonresident fees for their students. These sums vary considerably in amount. Toronto charges \$5 for first year students and \$10 for others. Five schools charge \$50 or less annually. Four schools (Georgia, Indiana, Louisiana State and Dartmouth) have an annual nonresident fee of \$400 or more. Dartmouth charges \$460 annually, the highest fee for nonresidents.

INTERNSHIPS AND RESIDENCIES

POSTWAR GRADUATE TRAINING

One of the major responsibilities of the medical profession today is the development of adequate facilities and opportunities for the advanced training of physicians returning from military service. Anticipating this need, the Council on Medical Education and Hospitals began more than a year ago to make a careful investigation of the educational facilities in the graduate and postgraduate fields. Nearly 1,300 institutions and agencies, including medical schools, hospitals, departments of health, state medical associations and specialty boards, were requested to furnish information regarding training programs now available or under consideration in relation to possible postwar needs. The response was encouraging, for it showed constructive planning already under way and also an earnest desire on the part of all groups concerned to cooperate to the fullest extent in meeting whatever demands the future may impose. A preliminary report on this study was published in *THE JOURNAL*, Jan. 1, 1944.

It is recognized that various kinds of training programs will be required, such as refresher and review courses, graduate lectures and clinics, continuation internships, hospital residencies, fellowships, basic medical science studies, individual preceptorships, graduate externships and perhaps other forms. The probable demand for postwar training is not yet fully known, but this question is now being studied by the Committee on Postwar Medical Service working in collaboration with the Surgeons General of the Army, Navy and Public Health Service. An analysis of the initial survey involving 3,000 medical officers was published in *THE JOURNAL*, June 24, 1944. A further report appears in the present issue of *THE JOURNAL*, page 1099.

These studies of the postwar educational desires of medical officers will facilitate further intelligent planning in the development and organization of suitable training programs. The Council in cooperation with the Committee on Postwar Medical Service and the examining boards in medical specialties will continue its activities in the field of postwar graduate medical education and will prepare, as soon as possible, a list of all available educational opportunities designed to meet the needs of returning medical officers.

NECROPSY PERFORMANCE

Under the present accelerated program of medical education it is particularly essential that all requirements of the internship be fulfilled so that young physicians may receive adequate preparation for civilian and military service. It has long been recognized that one of the most important functions in the training of interns is the correlation of clinical and pathologic studies. Any deficiency in pathologic material, therefore, will seriously impair the quality of house staff instruction.

The success of a necropsy program will in the final analysis depend on the whole hearted cooperation of the medical staff, interns and resident physicians, administrative officers and other hospital personnel. It is important that a necropsy study be requested on all hospital deaths, both private and ward, for each service should contribute its proportionate share to the educational program. The individual departments should likewise furnish a minimum of 15 per cent, so that a well balanced supply of pathologic material may be available

for teaching. If one service fails to provide the requisite amount, an added burden must necessarily be placed on other departments if a satisfactory rate is to be accomplished for the hospital as a whole. To insure that postmortem examinations are requested on all deaths, it is suggested that house officers be required in each instance to file a report in the superintendent's office containing either a signed permit or a notation why the necropsy could not be obtained. This procedure has been extremely helpful in many hospitals, for it creates further interest among the medical staff and serves to stimulate the interns and residents to greater effort.

The Council is cognizant of the many difficulties confronting hospitals at the present time, yet its responsibility in the maintenance of educational standards is such that it cannot justifiably continue the approval of intern training programs that are unable in a reasonable length of time to correct deficiencies in necropsy performance. It is strongly urged, therefore, that hospitals with low necropsy rates should immediately exert every effort to obtain sufficient material for instruction. The ratio of necropsies, it should be noted, has long been regarded as a reliable index of the quality of educational service in hospitals.

LATIN AMERICAN PHYSICIANS

The Council is deeply interested in the development of educational opportunities for Latin American physicians, who are coming to this country in increasing numbers for graduate training. The decline of learning and science, including medical education, in Europe during the war will tend to increase the importance of the United States as a center for advanced training for years to come. Thus we may expect a continual increase in the number of Latin American physicians who will be seeking further training in the schools and hospitals of the United States. This tendency deserves the full support of the medical profession in this country, which will share in a mutually beneficial exchange of ideas and the cementing of lasting inter-American friendships.

A study is now being made by the Council to determine the number of Latin American physicians currently in training in the United States, the type of training involved and the extent to which educational facilities in hospitals may need to be expanded to meet possible future needs. Qualified medical graduates of Latin American schools may from the Council's point of view serve as interns and resident physicians in approved hospitals. To assist such applicants in obtaining suitable appointments, lists of available internships and residencies will be prepared and will also be furnished to the various agencies that are interested in the training of medical personnel from the other American republics. The Council has already established contacts with the following Washington agencies: the Institute of International Education, the Division of Science, Education and Art of the State Department, the Office of the Coordinator of Inter-American Affairs and the Pan American Sanitary Bureau.

The Directing Board of the Procurement and Assignment Service has announced that graduates of Latin American schools will not be counted in hospital quotas. This ruling should do much to facilitate the appointment of Latin American physicians and thus help to establish a wider scope of hospital training in the United States.

THE 9-9-9 PROGRAM

On Jan. 1, 1944 the Procurement and Assignment Service instituted the 9-9-9 plan of internships, assistant residencies and residencies. This program created an internship of nine months duration for medical graduates holding a reserve commission, an assistant residency of nine additional months for one third of the group and a further residency of nine months available to one half of the commissioned officers receiving assistant residency training. The purpose of this plan was to provide a more equitable distribution of house officers in the interest of civilian hospital care, to insure the maintenance of at least a partial house staff at the assistant residency and residency levels and to create a more rapid supply of young medical officers for the armed forces than would be available under a twelve months internship with no further deferments for reserve officers.

In the allocation of interns and resident physicians, state quotas were established, individual hospitals receiving approximately 60 per cent of the number of house officers actually on duty in 1940. Allowances were made, however, for increased patient loads, teaching obligations and other significant factors. The state office of the Procurement and Assignment Service was permitted to make certain minor adjustments as warranted in individual cases, but otherwise the hospitals were expected to follow the quotas originally assigned for the nine months period.

The Council on Medical Education and Hospitals was asked by the Procurement and Assignment Service to act as a clearing house for hospitals with unfilled quotas and for interns and residents seeking hospital appointments. In accordance with this request, lists of hospitals needing interns and resident physicians have been published in *THE JOURNAL* at weekly intervals since November 1943. This service has been effective in meeting the needs of many institutions and applicants and will be continued as a means of assisting hospitals and medical graduates in obtaining house staff appointments.

The 9-9-9 program cannot be defended on purely educational grounds, yet it was the only method of deferment of commissioned officers as assistant residents and residents on which agreement could be reached. The only alternative was the continuance of the twelve months internship without any opportunity of further deferment. This was considered less desirable, for it had already been shown that under the accelerated program of medical education graduations every nine months integrated poorly with the one year internship. As a result, wasteful overlaps occurred during which the educational returns to the house officer were minimal. After considering the advantages and disadvantages and weighing the possible alternatives, it is recognized that the 9-9-9 program is the best available plan under present wartime conditions. Being created only as a war emergency measure, it should be discontinued as soon as conditions will permit the reestablishment of the regular training programs.

APPROVED INTERNSHIPS AND RESIDENCIES

In the standardization and approval of hospitals, the Council is primarily concerned with the development of high grade educational services for the continued training of medical graduates. The main consideration in this work is the organization of training programs in full compliance with the standards of the Council. It is also essential that a sufficient number of approved

1. Includes fellowships.

2. This total is not a complete report of available peacetime facilities, since some hospitals failed to report residencies temporarily discontinued under the present quota system.

* Number of hospitals approved for residency training, 675.

services be available so that all applicants may have an opportunity to obtain acceptable hospital training.

With the steady increase in number of approved intern hospitals, the question has arisen whether the Council is approving more internships than is warranted by the demand for them in normal times. This appears not to be the case.

The peacetime requirements can best be understood in relation to the growth and development of internships since 1914, when the first list of approved hospitals was published by the American Medical Association. In that year there were 508 general hospitals approved, 2,667 internships available and 3,594 medical graduates. Not until 1926, when 4,727 internships and 3,962 medical graduates were reported, did hospital facilities begin to exceed the number of students graduating each year. By 1941, however, the internships had reached a total of 8,100, whereas the number of graduates was only 5,200.

While it would seem that the shortage of house officers in recent years might be attributed mainly to this apparent overproduction of available internships, it should be noted that under ordinary conditions the size of the graduating class does not determine the number of interns engaged in hospital service. In 1939, for example, when there were 5,089 medical graduates in the United States, the approved hospitals reported 7,765 internships and 7,448 interns actually on duty. This represents a ratio of interns to medical graduates of 1.46 to 1. If the available internships are compared with the number of interns, a proportion of 1.04:1 is obtained. The corresponding ratios for 1940 are 1.5:1 and 1.04:1. This indicates that under normal conditions it is necessary to provide internships far in excess of the number of students graduating each year. In the two years cited, the annual number of interns

equaled approximately one and one-half times the number of medical graduates in the United States.

At the present time there are 710 civilian hospitals approved for intern training, which report a total of 5,438 internships. In January the approved hospitals had 5,170 interns on duty, as shown in table 26.

Included in the intern list of 1914 were 95 special hospitals, which could accommodate 428 applicants. This classification of special services was continued until 1927, when a separate residency list was established by the Council. The first list contained the names of 278 hospitals, which reported a total of 1,776 residencies. Since 1927, however, the facilities for specialized hospital training have more than tripled in number. This indicates not only a growing professional interest in specialization but also an evident desire on the part of hospitals to assist in the advanced training of young physicians. The highest number of available residencies was apparently reached in January 1943, when a total of 5,796 positions were listed in 722 approved hospitals. These included 1,762 assistant residencies, 3,323 residencies and 711 fellowships.

Under the new quota system many of the residencies have been discontinued, but these will no doubt be reestablished as soon as conditions again become favorable. Additional training programs will also be organized in relation to postwar needs, as previously mentioned in this report. From reports received early this year, it has been calculated that a total of 5,393 residencies, assistant residencies and fellowships are available in the civilian hospitals approved for residency training. This figure relates to normal peacetime resident requirements but should not be regarded as a complete report, since many of the hospitals did not include the residencies that have recently been discontinued. A classification of residencies by types of service is shown in table 27.

GRADUATE CONTINUATION COURSES FOR PRACTICING PHYSICIANS

The necessity for continuation courses of study in the medical specialties has never been more urgent than at the present time. Physicians in civilian practice have been compelled to enlarge their field of activity and to refresh their knowledge of the intricacies of modern diagnosis and treatment. Physicians in military service and returning medical officers are also encountering problems. The demand for all means of instruction is greater than it has ever been. Medical educators and interested agencies throughout the country are attempting to assist physicians called on to assume new responsibilities by offering refresher courses or continuation courses and by the presentation of scientific papers or lectures on timely subjects. These individuals, who will give or have given so generously of their time to participate in the instructional programs, constitute a large and distinguished faculty of medicine. The efforts of individual physicians with their increasing personal responsibilities and institutions and other agencies with greatly depleted staffs to assist in the presentation of these opportunities is noteworthy.

The Council on Medical Education and Hospitals publishes semiannually advance information concerning postgraduate continuation courses for practicing physicians. These include courses in a wide variety of fields in clinical medicine and the basic sciences. The courses are for variable periods from a few days to several

months. Some are concentrated full time courses and others are part time. In *THE JOURNAL* for July 8, 1944 there were listed 331 such courses available during the latter half of the current year. The opportunities listed are offered by hospitals, medical schools, graduate medical schools or other agencies in twenty-six states and include thirty-eight specialty or subspecialty subjects. Institutions offering continuation courses are invited to announce such courses in these semiannual lists compiled by the Council.

In the following paragraphs mention is made of some of the recent and noteworthy developments in graduate education. An analysis of the courses offered during the period July 1, 1943 to June 30, 1944 is also presented.

RECENT DEVELOPMENTS

The United States Public Health Service is planning to offer a three weeks course at Hot Springs National Park, Arkansas, in the management and control of the venereal diseases. Also under the auspices of the Public Health Service 15 to 20 physicians are appointed to traineeships in the diagnosis and treatment of cancer. Appointments are for one year. If satisfactory progress has been made, a trainee may be appointed for a second year and again for a third year. Trainees receive a stipend of \$6 a day.

The fifteenth annual postgraduate symposium on heart disease will be given in California in November at the Los Angeles County Hospital. This symposium is sponsored by the Los Angeles Heart Association and the Los Angeles Tuberculosis and Health Association.

The staff of the Georgia Warm Springs Foundation is again offering to practicing physicians a five day course in the treatment of acute and convalescent poliomyelitis sponsored by the Post Graduate School of Physical Therapy of the foundation through a grant from the National Foundation for Infantile Paralysis.

The Institute for Psychoanalysis, Chicago, together with the University of Illinois, has developed a course in psychosomatic medicine which will be offered during the coming fall quarter and will be available to physicians, interns and residents. No fee will be charged.

The twenty-ninth annual postgraduate medical teaching venture sponsored by the Inter-State Postgraduate Medical Association of North America will be held in Chicago, Oct. 17-20, 1944. The sponsoring agencies this year are the Illinois State Medical Society and the Chicago Medical Society. The Chicago hospitals, clinics and medical schools will furnish clinical material.

An intensive two weeks postgraduate course in obstetrics consisting of lectures, laboratory methods, bedside instruction and observation of complicated deliveries is offered four times during the school year by Indiana University School of Medicine.

Two refresher courses in obstetrics, each of two weeks' duration, will be given at Louisiana State University School of Medicine sponsored by the Louisiana State Board of Health. The courses are financed from Social Security funds allocated by the Children's Bureau, U. S. Department of Labor.

The University of Michigan School of Public Health will give courses in tropical diseases, industrial health and public health economics. Eight months' academic and field training is offered continuously. The School of Public Health, in cooperation with field facilities provided by the W. K. Kellogg Foundation, the Michigan State Department of Health, the Detroit Department of Health, the General Motors Corporation, the Chrysler Corporation, the Ford Motor Company and other organizations in nearby communities, is also prepared at all times to give special instruction in all phases of public health practice.

No hospital clinics were given by the Kansas City Southwest Clinical Society during the past year. However, a series of lectures and symposiums will be held in affiliation with the University of Kansas School of Medicine.

A ten weeks intensive course in venereal diseases for practicing physicians is given continuously at the Bureau of Social Hygiene by the New York State Department of Health in cooperation with the United States Public Health Service. This course involves every phase of the clinical and public health aspects of venereal diseases.

The New York Academy of Medicine's Annual Fort-night will be devoted to "Infections and Their Treatment." Special emphasis will be placed on the more recent chemotherapeutic agents.

Courses in public health and related fields for one quarter are offered by the University of North Carolina School of Public Health in cooperation with the United States Public Health Service, the Children's Bureau, the Reynold's Foundation and the Rockefeller Foundation.

Duke University's contribution to postgraduate work consists of internships from one to two weeks for physi-

cians in practice. Graduates are invited to the various clinics in medicine, surgery, obstetrics and other specialties and the clinical pathologic conferences held weekly.

The Ohio State Medical Association holds annually a forum on allergy. During the present year it is beginning a series of lectures planned to run for five years, at which it is planned to have lectures on the fundamentals of allergy.

A course in caudal analgesia of one week is offered by the Philadelphia Lying-In Hospital subsidized by the United States Public Health Service.

The Pennsylvania Department of Health, Division of Health Education, and collaborating agencies, are sponsoring a series of health institutes throughout the state to discuss wartime health problems of the commonwealth. Leaders of the medical, dental and nursing professions in Pennsylvania and nationally known public health experts have taken part in these institutes. The first regional health institute was held in Erie in November. At this first institute twenty-two agencies participated.

Postgraduate courses are offered continuously throughout the year in Tennessee. The state is divided into ten districts, and the instructor circulates in the district for a period of ten weeks. This development is sponsored by the Tennessee State Medical Association. There are six centers in each district. At each center the instructor spends a day.

The University of Wisconsin offers opportunities for observation courses at the Wisconsin General Hospital, Madison. Physicians may come at any time for a period of from one to five months.

Refresher courses will again be offered by the American College of Physicians in the autumn of 1944. Such courses will be given in Illinois, Massachusetts, Minnesota, New York, Oregon and Pennsylvania.

The American Academy of Ophthalmology and Otolaryngology offers a home study course in ophthalmology or otolaryngology, or both, on the first of each month. The registrant is sent a selected list of reading on the topic of that month, which it is estimated should require one to two and one-half hours daily. On the last of each month a series of twenty questions on the reading of the past month is sent to each registrant. The answers are corrected, graded and returned to the registrant. These home study courses have been carried on for five years and have been oversubscribed every year. The value of these home study courses is recognized by the specialty boards, and registrants are recommended for residencies and candidates for board certification, although it is specifically understood that completion of the academy courses does not necessarily fulfil the requirements of the boards for fundamental training.

The value of refresher or continuation courses in the postwar plans of graduate education for returning medical officers is referred to in the analysis presented on page 1099 of this issue of *THE JOURNAL*.

The excellent opportunities outlined are mentioned to present the variability of the courses being offered throughout the country. *THE JOURNAL* for July 8, 1944 presents these and many others in detail. Mention should also be made of the systematic courses offered by organized graduate schools including Tulane, Hopkins, Harvard, Tufts, the Center for Continuation Study of the University of Minnesota, Buffalo, Columbia, the New York Polyclinic, the University of Pennsylvania and many others.

Systematic courses formerly given in many instances have been discontinued because of the war emergency, the shortage of teaching personnel and transportation difficulties. In other instances, however, new opportunities are being developed and further efforts are encouraged, since there is a real need for an equal geographic distribution of such opportunities.

ANALYSIS OF COURSES OFFERED IN 1943-1944

In presenting this analysis of graduate and postgraduate courses which have been offered during the annual period July 1, 1943 to July 1, 1944 the statistical summaries are divided into three groups: courses in which instruction was offered to physicians in or near their home communities, courses providing ample facilities for clinical instruction and, lastly, a group including clinical conferences, graduate assemblies, study courses and so forth.

Eight states (Illinois, Kansas, Massachusetts, Michigan, New York, Oklahoma, Tennessee and Wisconsin) provided opportunities for physicians to continue professional study in or near their home communities. These courses reached approximately sixty-seven centers within these states. Subjects of these courses included cardiology, chest diseases, general medicine, industrial medicine, military medicine, ophthalmology and otolaryngology, public health, surgical diagnosis, tropical diseases and venereal diseases. The War Sessions of the American College of Surgeons, consisting of a full day's program, were available in the winter and spring months in fifteen states.

Agencies which were active participants in providing these opportunities, either independently or jointly, included state and county medical societies in Illinois, Kansas, Massachusetts, Michigan, Oklahoma, Tennessee and Wisconsin, the two medical schools in Michigan, the University of Kansas, Albany Medical College, Vanderbilt University and the University of Tennessee. The state departments of health in Kansas, New York and Tennessee were active in cooperating in programs in those states. Other agencies included the Commonwealth Fund and the Horace H. and Mary A. Rackham Fund.

Sessions of one day were most common and consisted of both didactic and clinical instruction, didactic instruction being most commonly given. The facilities of hospitals, clinics and hotels were used for presentation of this type of instruction. The instructors for these extramural courses were chosen from physicians practicing in the state in which the courses were offered as well as from out of state men. The faculties of 11 medical schools made a large contribution to the teaching staff for these courses. No fee was charged in the majority of instances. The War Sessions of the American College of Surgeons attracted about 17,000 physicians. The attendance reported for other opportunities was 3,955.

In 1943 sixteen states offered this type of instruction in more than eighty centers, with an attendance of 4,500. Transportation and other difficulties greatly curtailed the sponsoring of these courses itinerant in nature, but while they were limited to eight states last year, exclusive of the war sessions of the American College of Surgeons, the increasing recognition of their value was evidenced in that 3,955 attended courses in sixty-seven centers in these eight states.

Two hundred physicians enrolled for the home study course conducted by the American Academy of Ophthalmology and Otolaryngology last year.

Altogether, opportunities were made available on general-medical subjects in cities in or near their home communities to 20,955 physicians.

In centers where ample clinical facilities are available, 382 graduate courses of less than one year's duration were offered in nineteen states and the District of Columbia. These states and the number of courses which were given in each of these states during 1943-1944 are as follows:

Alabama	1	Michigan	24
California	14	Mississippi	1
District of Columbia	2	New Jersey	2
Georgia	1	New York	242
Illinois	24	North Carolina	1
Indiana	2	Ohio	2
Kansas	11	Pennsylvania	10
Kentucky	1	South Carolina	1
Louisiana	14	Texas	1
Massachusetts	26	Virginia	2

Seventy-seven agencies or combinations of agencies participated in the planning of the programs. Three graduate schools of medicine played the most prominent part in offering courses of this nature. Seventeen undergraduate medical schools have given such courses. Seven state medical societies independently or in collaboration with state health departments planned courses for physicians of the state. Six state health departments and four city or county medical societies made contributions. In eight instances hospitals were the agencies offering short periods of study. Other sponsors included thirteen special societies, the American College of Physicians, National Foundation for Infantile Paralysis, Institute for Psychoanalysis in Chicago, Rutgers University, American Institute for Psychoanalysis, Trudeau School of Tuberculosis, Horace H. and Mary A. Rackham Fund, Lillia Babbit Hyde Foundation and the Commonwealth Fund. Government agencies included the United States Public Health Service, the office of the Surgeon General of the United States Army, the Federal Security Agency and the office of the Coordinator of Inter-American Affairs.

While the majority of the courses were in various subjects as the demand seemed apparent, specific courses in neurology and psychiatry were offered in fifty-three instances, ophthalmology in thirty-three, general medicine in twenty-seven, obstetrics and gynecology in twenty-three, general surgery in twenty-two, cardiovascular-renal diseases in nineteen, otolaryngology in eighteen, dermatology and syphilology in seventeen, electrocardiology and radiology fourteen each and gastroenterology in thirteen. Fewer than ten courses were offered in allergy, anatomy, anesthesia, arthritis, bronchoscopy, cystoscopy and endoscopy, chemistry, chest diseases, diabetes, electroencephalography, endocrinology, industrial medicine, internal medicine, hematology, infantile paralysis, legal medicine, nutrition, otorhinolaryngology, orthopedics, parasitology, pathology, pediatrics, physical therapy, physiology, plastic surgery, proctology, therapeutics, tropical medicine, urology, venereal disease control and war medicine.

The description of these intensive courses gave evidence that the type of instruction was both clinical and didactic. In presenting graduate courses medical school facilities were used for 194 courses, hospitals for 230 and clinics for 127. In many instances two or all three of these sources were used in presenting an individual course. Hotels and other facilities were used for 26 courses. The faculties of the medical schools served as instructors in 249 courses. Additional instructors were specialists in their fields chosen mainly from physicians residing within the state in which the course was given but including as well

physicians from outside the state. The duration of study in centers with clinical facilities varied from ten hours to one year. Many courses were of five days and one, two, four, six and eight weeks' duration as well as ten and twelve weeks and two months. Sixteen were courses of longer than three months, and one was a year's course. Courses were offered during every month last year and in thirty-eight instances they were arranged to suit the convenience of physician-students. Sixty-five courses were available for specialists only. Fees ranged from 50 cents to \$800. For seventeen courses no fee was charged, while in eight medical officers paid no fees or a nominal fee. The attendance reported for 364 of these courses was 8,888. Eighteen did not record attendance. This figure approximates that reported in 1943 for 440 similar courses.

Clinical conferences and graduate assemblies of less than five days were held in fourteen states and the District of Columbia as follows:

Colorado	New York
Connecticut	Ohio
District of Columbia	Pennsylvania
Illinois	South Carolina
Louisiana	Texas
Michigan	Virginia
Missouri	Wisconsin
Nebraska	

Thirty-one such opportunities were offered. This type of study was sponsored by four medical schools, six state medical societies, nine city or county medical societies, twenty-six special societies, one hospital and the United States Public Health Service. Study courses in a variety of subjects were offered. The assemblies were held in centers with facilities for clinical and practical work and for scientific exhibits. In addition the American College of Physicians held wartime regional meetings in a number of states. Instruction was both didactic and clinical. The instructors included physicians residing in the state where the assembly was held, physicians from other states and members of the professorial faculties of medical schools. One or more of these assemblies was given in every month last year. Registration fees ranged from no fee in fifteen instances to \$10. The total recorded attendance was 16,718. In 1943 the attendance for fifty-two such opportunities was 15,301.

For all three types of training offered during 1943-1944 the attendance was greater than the previous year,

when more individual opportunities were available throughout the country, indicating increasing recognition of this refresher type of training. Altogether 46,561 physicians were interested in some form of graduate education last year. This figure excludes physicians who were enrolled for courses of longer than a year's duration as well as those serving internships and residencies and physicians who attended the Wartime Graduate Medical Meetings.

WARTIME GRADUATE MEDICAL MEETINGS

Under the auspices of a committee representing the American Medical Association, the American College of Physicians and the American College of Surgeons, a series of Wartime Graduate Medical Meetings has been held. These programs have been organized for physicians in the Army, Navy and Public Health Service and for physicians in civilian life who are resident within reasonable traveling distance of the camps and hospitals in which these postgraduate opportunities are offered. For organizational purposes the country has been divided into twenty-four sections, and key committees of three men have been appointed in each section to carry on the details of the program. In order to insure the best results a group of qualified authorities has been designated to serve as national consultants in the various special fields. Likewise the Surgeon Generals of the Army, Navy and Public Health Service have appointed a committee of three, one man from each organization, to collaborate in the work of administration.

From July 1, 1943 to June 30, 1944 there have been 199 programs. Ninety-five of these were continuation courses in which meetings were held at the same installation at regular intervals. The total number of daily sessions of all wartime graduate medical meetings during this year was 952. Programs have been conducted in forty-one states and in Canada. Attendance has not been reported routinely, but it is estimated that well over 30,000 physicians have profited by these meetings. It is not possible to determine what proportion were military or civilian doctors. In the near future the committee in charge of the Wartime Graduate Medical Meetings will meet with the Committee on Postwar Medical Service to consider plans for the future, which will naturally depend on military events.

EXAMINING BOARDS IN THE MEDICAL SPECIALTIES

In 1933 the Council on Medical Education and Hospitals was instructed by the House of Delegates of the American Medical Association to formulate minimal essentials deemed necessary for certification as a specialist. Prior to 1934 there were five examining boards in the medical specialties functioning. Other boards were later organized, and since 1940 fifteen boards have been in operation. All these boards are fully approved by the Council.

The Council's "Essentials of Approved Examining Boards in Medical Specialties" outlines the type of organization and the responsibilities of such boards as well as the minimum qualifications deemed necessary for the certification of a specialist. Such qualifications

include graduation from an approved medical school, completion of an internship in a hospital approved by the Council, three additional years of special training in institutions approved by the Council and the board concerned, and a further period of two years devoted to specialty study and/or practice. Some boards require more than this minimum training. Each board has published a booklet containing a brief statement regarding its organization, personnel, purposes and requirements for certification. A statement of these requirements for each board was given in detail in the 1942 Educational Number of *THE JOURNAL*.

The Advisory Board for Medical Specialties was organized in 1933-1934 to coordinate graduate edu-

TABLE 28.—Approved Examining Boards in Medical Specialties

Key No.	Name of Board	Year of Incorporation	Total Certificates Awarded to	
			March 1, 1943	March 30, 1944
A. B. 1.	American Board of Pediatrics. Pres., Edward B. Shaw, 384 Post St., San Francisco, Calif. Sec., C. A. Aldrich, 115½ First Ave. S.W., Rochester, Minn.	1933	2,053	2,220
A. B. 2.	American Board of Psychiatry and Neurology Act. Pres., Hans A. Reese, Wisconsin General Hospital, Madison, Wis. Sec., Walter Freeman, 1023 Connecticut Ave., N.W., Washington, D. C.	1934	1,536	1,716
A. B. 3.	American Board of Orthopaedic Surgery Pres., Frank D. Dickson, 1400 Professional Bldg., Kansas City, Mo. Sec., Guy A. Caldwell, 3503 Prytania St., New Orleans, La.	1934	819	860
A. B. 4.	American Board of Dermatology and Syphilology Pres., Howard Fox, 140 E. 54th St., New York City, N. Y. Sec., George M. Lewis, 121 E. 60th St., New York City, N. Y.	1932	644	650
A. B. 5.	American Board of Radiology Pres., John W. Pierson, 1107 St. Paul St., Baltimore, Md. Sec., Byrl R. Kirkin, 102-110 Second Ave. S.W., Rochester, Minn.	1934	1,881	2,012
A. B. 6.	American Board of Urology Acting Pres. and Sec., Gilbert J. Thomas, 1409 Willow St., Minneapolis, Minn.	1935	942	983
A. B. 7.	American Board of Obstetrics and Gynecology Pres., W. T. Dannreuther, 380 Park Ave., New York City, N. Y. Sec., Paul Titus, 1015 Highland Bldg., Pittsburgh, Pa.	1930	1,656	1,764
A. B. 8.	American Board of Internal Medicine Chairman, Reginald Fitz, 319 Longwood Ave., Boston, Mass. Asst. Sec., W. A. Werrell, 1301 University Ave., Madison, Wis.	1936	2,903	3,263
A. B. 9.	American Board of Pathology Pres., Arthur H. Sanford, 102 Second Ave. S.W., Rochester, Minn. Sec., F. W. Hartman, Henry Ford Hospital, Detroit, Mich.	1930	954	1,012
A. B. 10.	American Board of Ophthalmology Chairman, John Green, 3720 Washington Blvd., St. Louis, Mo. Sec., S. Judd Beach, 56 Irie Rd., Cape Cottage, Me.	1917	2,198	2,336
A. B. 11.	American Board of Otolaryngology Pres., Harris P. Mosher, 127 Front St., Marblehead, Mass. Sec., Dean M. Lierle, University Hospital, Iowa City, Ia.	1924	3,570	3,737
A. B. 12.	American Board of Surgery Chairman, Arthur W. Elting, 119 Washington Ave., Albany, N. Y. Sec., J. S. Rodman, 225 S. 15th St., Philadelphia, Pa.	1937	2,144	2,342
A. B. 13.	American Board of Anesthesiology Pres., H. Boyd Stewart, 27th Place, Tulsa, Okla. Sec., Paul M. Wood, 745 Fifth Ave., New York City, N. Y.	1938	188	231
A. B. 14.	American Board of Plastic Surgery Chairman, John S. Davis, 135 E. 65th St., Baltimore, Md. Sec., James B. Brown, 400 Metropolitan Bldg., St. Louis, Mo.	1937	154	160
A. B. 15.	American Board of Neurological Surgery Chairman, Howard C. Naffziger, 384 Post St., San Francisco, Calif. Sec., Paul C. Bucy, 912 S. Wood St., Chicago, Ill. Advisory Board for Medical Specialties Pres., Willard C. Rappleye, 630 W. 168th St., New York City, N. Y. Sec., Byrl R. Kirkin, 102-110 Second Ave. S.W., Rochester, Minn.	1940	50	149
Totals.....			21,699	23,465

Certification in the subspecialties: By the American Board of Internal Medicine: allergy 71, cardiovascular disease 310, gastroenterology 149, tuberculosis 128, total 658. By the American Board of Surgery: proctology 70. Total certified in the subspecialties, 728. These figures are included in the above tabulation.

cation and certification of medical specialists in the United States and Canada. This board reports directly to its member groups and functions in close cooperation with the Council on Medical Education and Hospitals of the American Medical Association.

The American Board of Internal Medicine by special examination certifies specialists in allergy, cardiovascular disease, gastroenterology and tuberculosis. Similarly the American Board of Surgery certifies specialists in proctology. Regular board certification is a prerequisite for certification in the subspecialty.

A list of the Specialty Boards and their officers and the number of certificates awarded prior to March 1, 1943 and the number certified to March 30, 1944, respectively, appear in table 28. On March 1, 1943 there were 21,699 physicians certified by the fifteen specialty boards, and in the following year 1,766 were certified. On March 30, 1944 a total of 23,465 certificates had been issued.

Included in these figures are 728 who have been certified in the following subspecialties: allergy 71, cardiovascular disease 310, gastroenterology 149, proctology 70 and tuberculosis 128.

In internal medicine 3,263 have been certified and in general surgery 2,342. However, the greatest number in any one specialty certified was in otolaryngology. In this specialty 3,737 have received the board's certificate since the organization of this board in 1924. The board in ophthalmology, organized in 1917 and the oldest board in existence, has to date certified 2,336. There has been a tripling in the past year in the number certified in neurologic surgery, which was formulated in 1940 and is the last board organized.

A key number has been assigned to each approved specialty board, such as A. B. 1, and the biographic records of physicians published in the American Medical Directory include by this means reference to those certified by these boards.

The 9-9-9 program curtails the training of numbers of young physicians desiring specialty certification. Under this wartime program the various boards will probably allow credit for the actual time spent by the candidate in house officer training in approved hospitals.

The majority of the boards will grant some credit for military service which will compensate in part for the interruption of the graduate training of physicians by military exigencies. The policies adopted by the specialty boards vary considerably. One grants an indefinite amount of credit, to be determined by an evaluation of the experience of individual applicants. Another grants full credit for work done in the surgical division of a regularly constituted army or naval hospital. Most boards limit the credit allowed to one year of training and/or one year of experience. The special provisions for military medical credit made by each board were published in the 1943 Educational Number of THE JOURNAL.

Prospective applicants who are in military services should obtain a copy of the "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards" from the secretary of any board. This booklet describes procedures pertaining to military credit and will enable prospective applicants and candidates to keep an accurate account of work done in the military service and will constitute part of the credentials to be submitted to the board on application for certification.

APPROVED MEDICAL SCHOOLS

ARKANSAS

Little Rock

UNIVERSITY OF ARKANSAS SCHOOL OF MEDICINE, 1209 McAlmont Street.—Organized in 1879 as the Medical Department of Arkansas Industrial University. Present title in 1899. In 1911 the College of Physicians and Surgeons united with it and it became an integral part of the University of Arkansas. The first class was graduated in 1880. Clinical teaching was suspended in 1918 but resumed in 1923. Coeducational since organization. The faculty consists of 30 professors and 117 lecturers and instructors, a total of 147. The curriculum covers four sessions of nine months each. Entrance requirements are two years of collegiate work. The B.S. Degree is conferred at the end of the second year. An accelerated program was adopted July 1, 1943, involving the admittance and graduation of a class approximately every nine months. The fees for the four years for residents of Arkansas are \$280 per year; nonresidents are charged \$225 additional each year. The registration for 1943-1944 was 279, graduates 60. The present session began April 3, 1944, and will end Dec. 18, 1944. The subsequent session will begin Jan. 2, 1945. The Dean is Byron L. Robinson, M.D.

CALIFORNIA

Berkeley-San Francisco 22

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL, University Campus, Berkeley; Medical Center, San Francisco.—Organized in 1864 as the Toland Medical College. The first class graduated in 1864. In 1873 it became the Medical Department of the University of California. In 1909, by legislative enactment, the College of Medicine of the University of Southern California, at Los Angeles, became a clinical department but was changed to a graduate school in 1914. In 1915 the Hahnemann Medical College of the Pacific was merged, and elective chairs in homeopathic materia medica, and therapeutics were provided. Coeducational since organization. Three years of collegiate work are required for admission. The work of the first year is given at Berkeley and that of the last three years at San Francisco. An accelerated program has been adopted consisting of three terms of sixteen weeks in each academic year. The medical course may now be completed in three years. The faculty is composed of 181 professors and 314 associates and assistants, a total of 495. The fees average \$318 per academic year; nonresidents are charged \$250 additional each year. The registration for 1943 was 282; graduates, 65. The last session began November 1, 1943, and ended June 24, 1944. The present session began June 30, 1944. The Dean is Francis Scott Smyth, M.D., San Francisco.

Loma Linda-Los Angeles 33

COLLEGE OF MEDICAL EVANGELISTS, Loma Linda; Boyle and Michigan Avenues, Los Angeles.—Organized in 1909. The first class graduated in 1914. The laboratory departments are at Loma Linda; the clinical departments at Los Angeles. Coeducational since organization. Three years of collegiate work are required for admission. The faculty is composed of 43 professors and 376 associate professors, assistant professors, instructors and assistants—making a total of 419. The course covers a period of three years of four nine-month academic sessions and an additional twelve-month (nine-month for military personnel) internship in an approved hospital. The total fees are, respectively, \$602, \$590, \$612 and \$620. The registration for 1943-1944 was 335; graduates 67. The present session for the freshmen and sophomore students began on Mar. 31 and will end December 21, 1944; the present sessions for the junior and senior students began on January 2 and will end September 24, 1944. The subsequent freshman session will begin Dec. 29, 1944. The President is Walter E. Macpherson, M.D., Los Angeles. The Dean is Newton G. Evans, M.D., Loma Linda. The Associate Dean is W. F. Norwood, Ph.D., Los Angeles.

Los Angeles 7

UNIVERSITY OF SOUTHERN CALIFORNIA SCHOOL OF MEDICINE, 3551 University Avenue. Organized in 1895 as the University of Southern California College of Medicine. First class graduated in 1888. In 1908 it became the Los Angeles Medical Department of the University of California. In 1909 the College of Physicians and Surgeons, established in 1904, became the Medical Department of the University of Southern California. Its activities were suspended in 1920; reorganized in May 1928, under present title. Entrance requirements are approximately 90 semester hours. During present national emergency will operate the year round on accelerated three term basis, each term continuing for sixteen weeks. The faculty consists of 189 professors, associate professors and assistant professors and 241 instructors, assistants and lecturers—a total of 430, 147 of whom are now on active duty with the armed forces. An internship is required for graduation. Coeducational since organization. Annual fees (1½ academic years) amount to \$852. The registration for 1943-1944 was 238, graduates 49. The present session began March 6, 1943-1944 was 238, graduates 49. The subsequent session begins October 30, 1944. The Dean is Burrell O. Raulston, M.D.

Stanford University-San Francisco

STANFORD UNIVERSITY SCHOOL OF MEDICINE, University Campus, Stanford University; 2398 Sacramento Street, San Francisco. The main buildings are in San Francisco. The laboratories of anatomy, bacteriology and experimental pathology, chemistry, and physiology are located on the campus at Stanford University, which is thirty miles southeast of San Francisco adjoining the City of Palo Alto. The post office is Stanford University. Organized in 1908, when by agreement the interests of Cooper Medical College were taken over. The first class graduated in 1913. Coeducational since organization. The faculty consists of 138 professors and 190 lecturers, assistants and others, a total of 328. Two years of collegiate work are required for admission. The quarter plan is in operation admitting one class each nine months. An internship is a requirement for graduation. The fees for the four years, respectively, are \$474, \$438, \$418 and \$418. The registration for 1943-44 was 242; graduates, 56. During 1944-45 the quarters begin October 9th, January 8th, April 9th, and July 9th. The Dean is Loren Roscoe Chandler, M.D.

COLORADO

Denver

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE, 4200 East Ninth Avenue.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years except 1898 and 1899. Denver and Gross College of Medicine was merged Jan. 1, 1911. Coeducational since organization. The faculty is composed of 57 professors and 130 lecturers, instructors and assistants, a total of 187. The accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The entrance requirements for nonmilitary students are three years of collegiate work. The fees average \$289 per academic year. Nonresidents are charged \$245 additional each year. The registration for 1943 was 235, graduates 56. The present session began Jan. 3, 1944 and will end Sept. 19, 1944. The subsequent session will begin Oct. 2, 1944. The Dean is Maurice H. Rees, M.D.

CONNECTICUT

New Haven

YALE UNIVERSITY SCHOOL OF MEDICINE, 333 Cedar Street.—Chartered in 1810 as the Medical Institution of Yale College. Organized in 1812; instruction began in 1813; first class graduated in 1814. A new charter in 1879 changed the name to the Medical Department of Yale College. In 1884, the Connecticut Medical Society surrendered such authority as had been granted by the first charter. In 1887, Yale College became Yale University. Coeducational since 1916. The faculty consists of 196 professors and 159 lecturers and assistants, a total of 355. Of this number, 28 are on leave of absence for war service and about 100 others have entered the armed forces upon completion of or during appointments. The requirements for admission are three years of collegiate work. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. The fees average \$506 per academic year. The registration for 1943 (April to December) was 233; graduates, 49. The present session began December 27, 1943 and will end September 16, 1944. The subsequent session will begin September 25, 1944. The Dean is Francis G. Blake, M.D.

DISTRICT OF COLUMBIA

Washington

GEORGETOWN UNIVERSITY SCHOOL OF MEDICINE, 3900 Reservoir Road, N.W.—Organized in 1851. First class graduated in 1852. The faculty is composed of 56 professors, 48 associate professors, 16 assistant professors, 13 adjunct professors and 145 instructors, a total of 278, of whom 72 are on military leave. Minimum requirements for admission are the complete premedical Army Specialized Training Program or Navy College Training Program. Civilian students must finish at least two full years of premedical work in an approved college of arts and sciences. The accelerated program permits admission and graduation of a class every nine months. The fees average \$520 per academic year. Registration for 1943 was 318, graduates 63. The current session began January 3, 1944 and will close September 16, 1944. The next session will begin October 2, 1944. The Dean is David V. McCauley, S.J., Ph.D.

GEORGE WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, 1335 H Street, N.W.—Organized in 1825 as the Medical Department of Columbian College. Also authorized to use the name National Medical College. Classes were graduated in 1826 and in all subsequent years except in 1834 to 1838, and 1861 to 1863, inclusive. The original title except in 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1904, 1903 it absorbed the National University Medical Department. In 1904, by an Act of Congress, the title of George Washington University was granted to the institution. Coeducational since 1881. The faculty is

composed of 81 professors and 150 instructors, demonstrators and assistants, a total of 231. Sixty semester hours of collegiate work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. The fees average \$550 per academic year. The registration for 1943 was 294, graduates, 65. The present session began November 22, 1943 and will end September 19, 1944. The subsequent session will begin September 18, 1944. The Dean is Walter A. Bloedorn, M.D.

HOWARD UNIVERSITY COLLEGE OF MEDICINE, Fifth and W Street, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Coeducational since organization. Negro students compose a majority of those in attendance. The faculty comprises 37 professors and 64 instructors and assistants, a total of 101. The admission requirements are at least two years of collegiate work. The course covers four years of thirty-three weeks each. Under our present accelerated program this work can be completed in three calendar years. The fees are, respectively, \$269.00, \$269.00, \$259.00 and \$266.00. Registration for 1943-1944 was 257, graduates, 48. The curriculum was accelerated with the beginning class of September 1942. The present class was admitted March 25, 1944 and will end Dec. 22, 1944. The subsequent session will begin Dec. 28, 1944. The Dean is John W. Lawlah, M.D.

GEORGIA

Atlanta 3

EMORY UNIVERSITY SCHOOL OF MEDICINE, 50 Armstrong Street—Organized in 1854 as the Atlanta Medical College. Classes graduated 1855 to 1861, when it suspended. Reorganized in 1865. A class graduated in 1865 and each subsequent year except 1874. In 1898 it merged with the Southern Medical College (organized in 1878), taking the name of Atlanta College of Physicians and Surgeons. In 1913 it merged with Atlanta School of Medicine (organized in 1905), reassuming the name of Atlanta Medical College. Became the Medical Department of Emory University in 1915, assumed present title in 1917. For civilian students three years of collegiate work are required for admission. Students in the armed services are admitted in accordance with regulations set up by them. The course of study is four academic years of thirty-two weeks each. By the use of the long summer vacation as a teaching quarter, the time required for the completion of these four academic years has been reduced from four to three calendar years. This is in line with the accelerated program adopted by most medical schools during the present emergency. The fees for each of the four academic years are \$400. The registration for 1943 was 739 graduates, 50. Classes this year began on Jan. 3, 1944 and will end Sept. 16, 1944. The subsequent session will begin Oct. 2, 1944. The Dean is Russell H. Oppenheimer, M.D.

Augusta

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE, University Place—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. After 1873 it was known as the Medical Department of the University of Georgia. On July 1, 1933, the name was changed to the University of Georgia School of Medicine. Property transferred to the University in 1911. Classes were graduated in 1833 and all subsequent years except 1862 and 1863. Coeducation was begun in 1920. The faculty includes 30 professors and 67 associate and assistant professors, instructors, lecturers and assistants, a total of 97. Of this number 17 are on military leave. Three years of collegiate work are required for admission (except that for the duration of the present war the minimum requirement will be two years). An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$225 per academic year for residents of Georgia, nonresidents, \$445. The registration for 1943 was 259, graduates, 43. The present session began January 3, 1944 and will end September 11, 1944. The subsequent session will begin September 27, 1944. The Dean is G. Lombard Kelly, M.D.

ILLINOIS

Chicago

LOYOLA UNIVERSITY SCHOOL OF MEDICINE, 706 South Wolcott Avenue—Organized in 1915 by acquisition of Bennett Medical College, which had been organized in 1869. Facilities enlarged upon by acquisition of Chicago College of Medicine and Surgery, faculties in basic medical sciences put on full time basis and present title assumed in 1917. Operated as an organic part of Loyola University. Coeducational since organization. The faculty is composed of 19 full time professors and 329 associate and assistant professors, associates, instructors and assistants, a total of 348. Sixty semester hours of collegiate work are required for admission. The fees average \$510.00 per academic year. The registration for 1943 was 312, graduates, 70. The present session began on January 10, 1944 and will end September 23, 1944. The subsequent session will begin October 2, 1944. The Dean is Italo F. Volini, M.D.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL, 303 East Chicago Avenue—Organized in 1859 as the Medical Department of Lind University. First class graduated in 1860. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869 but retained the name of Chicago Medical College until 1891, when the present title was taken. Became an integral part of Northwestern University in 1905. Coeducational since 1926. The faculty comprises

28 professors, 147 associate and assistant professors and 433 associates, instructors and clinical assistants, a total of 608. For the duration of the war the requirement for admission is two years of collegiate work. The B.S. in medicine degree may be conferred before the end of the senior year. An accelerated program has been adopted involving the acceptance of a class every nine months. A hospital internship is required for graduation. The total fees are \$414 each year. The registration for 1943 was 590, graduates, 161. The present session began December 28, 1943 and will end September 16, 1944. The subsequent session will begin September 27, 1944. The Dean is J. Roscoe Miller, M.D.

UNIVERSITY OF CHICAGO, THE SCHOOL OF MEDICINE, Fifty Eighth Street and Ellis Avenue—Organized in 1924, as a part of the Ogden Graduate School of Science of the University of Chicago. In 1932, when the University of Chicago reorganized its departments, the medical departments were included in the Biological Sciences Division. The work of the first two years in the medical courses has been given on the University Quadrangles since 1899, but the last two years were offered only at Rush Medical College which was affiliated with the university until 1927 when actual work in the clinical departments on the campus began. After that time, candidates for the degree of Doctor of Medicine could take the work of the first two years on the campus and the work of the third and fourth years either on the campus or at the Rush Medical College. In June 1940 Rush Medical College became affiliated with the University of Illinois College of Medicine. All undergraduate instruction is now given only on the campus of the University of Chicago. The faculty of the School of Medicine is composed of 90 professors, 125 associates, instructors and others, a total of 215. The requirements for admission are 80 semester hours of collegiate work or completion of the Army or Navy premedical program, whether or not the applicant is actually in the Army or Navy. The B.S. degree may be obtained during the second year. The curriculum covers twelve quarters of work. Sixty-five students are admitted to the first year class every nine months. The tuition fee averages \$450. The registration for 1943 was 271, graduates, 72. Quarters begin in March, June, September and December of each year. All correspondence relating to general policies should be addressed to A. C. Bachmeyer, M.D., Associate Dean of the Division of Biological Sciences, and that pertaining to student affairs to J. J. Mullin, Assistant Dean of Students.

UNIVERSITY OF ILLINOIS COLLEGE OF MEDICINE, 1855 West Polk Street, Zone 12—Organized in 1882 as the College of Physicians and Surgeons. The first class graduated in 1883. It became the Medical Department of the University of Illinois by affiliation in 1897. Relation ship with the university was canceled in June 1912, and was restored in March 1913, when the present title was assumed. The staff of the Rush Medical College was incorporated in the University of Illinois College of Medicine in 1942 and at the same time Presbyterian Hospital, Chicago, became a teaching unit of the university. Coeducational since 1898. Two years of collegiate work are required for admission. The accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The B.S. in medicine degree is conferred at the end of the second year. The faculty is composed of 250 professors and 250 associates, instructors and assistants, a total of 500. The fees for residents of Illinois average \$288 per academic year, non residents pay an additional fee of \$150. The registration for 1943-1944 was 676, graduates, 161. The present session began April 3, 1944 and will end December 13, 1944. The subsequent session will begin Jan. 2, 1945. The Dean is Raymond B. Allen, M.D.

INDIANA

Bloomington-Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE, Bloomington, 1040 West Michigan Street, Indianapolis—Organized in 1903 but did not give all the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1905 by the merger of the Medical College of Indiana (organized in 1878), the Central College of Physicians and Surgeons (organized in 1879), and the Fort Wayne College of Medicine (organized in 1879) merged into it. The first class was graduated in 1908. Coeducational since organization. The faculty consists of 331 professors, lecturers, associates and assistants. The B.S. degree in anatomy and physiology is conferred. The school has been on an all time program since May 11, 1942. Three years of college work are required for admission. Each calendar year is divided into three semesters. The work given in two semesters is equivalent to the work formerly given in a year. The work of the first two semesters is given at Bloomington, the remainder of the work at Indianapolis. Regular fee for two semesters of work is \$217 for residents of Indiana and \$422 for nonresidents. The registration for the session 1943 was 596, graduates, 124. The next regular class will start work on January 1, 1945. The Dean is Willis D. Gatch, M.D., Indianapolis.

IOWA

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE, University Campus—Organized in 1869. First session began in 1870. First class graduated in 1871. Absorbed Drake University College of Medicine in 1913. Coeducational since 1870. The faculty is made up of 56 profes

sors, 74 lecturers, demonstrators and assistants, a total of 130. Three years of collegiate work are required for admission. The B.A. degree in the combined course of liberal arts and medicine is conferred. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The tuition fee is \$226 each year for residents of Iowa and \$490 for nonresidents. The registration for 1943 was 317, graduates, 64. The present session began January 3, 1944 and will end September 23, 1944. The subsequent session will begin October 2, 1944. The Dean is Ewen Murchison MacEwen, M.D.

KANSAS

Lawrence-Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE, Lawrence, 39th Street and Rainbow Boulevard, Kansas City—Organized in 1880. It offered only the first two years of the medical course until 1905, when it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. Absorbed Kansas Medical College in 1913. The first class graduated in 1906. The clinical courses are given at Kansas City. Coeducational since 1880. The faculty includes 64 professors and 125 instructors, assistants and others, a total of 189. The requirement for admission is three years of collegiate work. Students must have collegiate degree to enter sophomore year. The B.S. degree in medicine is conferred at the end of the second year. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees for residents of the state average \$229.50, nonresidents \$439.50. The registration for 1943-1944 was 330, graduates, 83. The present session for freshmen began March 6, 1944. Upper classmen were enrolled Feb. 21, 1944 and will complete the year Oct. 30, 1944. The subsequent session will begin Oct. 30, 1944. The Dean is Harry R. Wahl, M.D., Kansas City.

KENTUCKY

Louisville 2

UNIVERSITY OF LOUISVILLE SCHOOL OF MEDICINE, 101 West Chestnut Street—Organized in 1837 as Louisville Medical Institute. The first class graduated in 1838, and a class graduated each subsequent year except 1863. In 1846 the name was changed to University of Louisville Medical Department. In 1907 it absorbed the Kentucky University Medical Department, in 1908, the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. In 1922 it changed its name to the University of Louisville School of Medicine. Coeducational since organization. Two years of collegiate work are the minimum requirement for admission. Preference is given applicants with a degree or three college years leading to a degree. The faculty numbers 73 professors and 73 assistants, instructors and others, a total of 146. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. Fees are \$450 for residents of Louisville and Jefferson County and \$550 for nonresidents per school year. The registration for 1943 was 363, graduates 88. The present session began January 5, 1944 and will end September 8, 1944. The subsequent session will begin September 27, 1944. The Dean is John Walker Moore, M.D.

LOUISIANA

New Orleans 13

LOUISIANA STATE UNIVERSITY SCHOOL OF MEDICINE 1542 Tulane Avenue—Organized January 1931 as Louisiana State University Medical Center. Present title in 1939. Coeducational. First session October 1931, with students of first and third year. Faculty comprises 28 professors and 77 associate professors, assistant professors, instructors and assistants, a total of 105. Course covers four sessions of not less than 32 weeks each. Under the accelerated program adopted for the duration of the war, a first year class will be admitted each year and the entire course will be completed within a period of three years from the date of admission. A minimum of three years collegiate work is required for admission. Total fees, \$134 each year for residents of Louisiana, additional tuition of \$400 each year for nonresidents. The registration for 1943 was 339, graduates, 79. The present session began January 11, 1944 and will end September 6, 1944. The subsequent session will begin September 27, 1944. The Dean is Beryl I. Burns, M.D.

TULANE UNIVERSITY OF LOUISIANA SCHOOL OF MEDICINE, 1430 Tulane Avenue—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years except 1863-1865, inclusive. It became the Medical Department of the Tulane University of Louisiana in 1884. Present title in 1913. Coeducational since 1915. The faculty comprises 34 professors and 240 associate and assistant professors, instructors and assistants, a total of 274. An accelerated program has been adopted involving the admittance of a class at the beginning of each tenth month and the graduating of a class approximately every nine months. A minimum of three years of collegiate work is required for admission. Total fees average \$347 per academic year. The registration for 1943-1944 was 529, graduates, 119. The present session began March 1, 1944 and will end October 14, 1944. The subsequent session will begin December 1, 1944. The Dean is Hiram W. Kostmayer, M.D.

MARYLAND

Baltimore

JOHNS HOPKINS UNIVERSITY SCHOOL OF MEDICINE, 710 North Washington Street—The nucleus of a Medical Faculty was constituted in 1833. Systematic postgraduate instruction in pathology and bacteriology was begun in 1886. School was fully organized and opened in 1893. The first class graduated in 1897. Coeducational since organization. The faculty consists of 72 professors and 399 instructors, assistants and others, a total of 471. The requirement for admission is temporarily two college years. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. The fees average \$627 per academic year. The registration for 1943 was 295, graduates, 69. The present session began November 29, 1943 and will end August 18, 1944. The subsequent class will begin September 25, 1944. The Dean is Alan M. Chesney, M.D.

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE AND COLLEGE OF PHYSICIANS AND SURGEONS, Lombard and Greene Streets, Zone 1—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. Baltimore Medical College was merged with it in 1913. In 1915 the College of Physicians and Surgeons of Baltimore was merged and the present name assumed. Coeducational since 1918. The faculty consists of 52 professors and 332 associate and assistant professors and others, a total of 384, of which 137 are now absent serving with the Armed Forces. Premedical college training reduced from three to two years for the duration of the war. The medical school is now running under an accelerated program for the duration of the war, and requires the admission of a freshman class approximately every nine months. The tuition fees average \$501 for residents of the state, for non residents approximately \$150 additional. The registration for the session 1943 was 371, graduates 90. Present session began January 13, 1944 and will end September 29, 1944. The next subsequent session will begin October 17, 1944. The Dean is Robert U. Patterson, M.D.

MASSACHUSETTS

Boston

BOSTON UNIVERSITY SCHOOL OF MEDICINE, 80 East Concord Street—Organized in 1873 as a homeopathic institution. In 1874 the New England Female Medical College, founded in 1848 was merged into it. The first class was graduated in 1874. Became nonsectarian in 1918. Coeducational since organization. For the duration two years of collegiate work are required for admission. The normal requirement for admission is three years of college work. The faculty includes 23 professors, 212 associate and assistant professors, instructors and others, a total of 235. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. Total fees average \$480 per year. The registration for 1943 was 248, graduates 46. The present session began December 31, 1943 and will end September 22, 1944. The subsequent session begins September 29, 1944. The Dean is Charles F. Branch, M.D.

HARVARD MEDICAL SCHOOL, 25 Shattuck Street, Zone 15—Organized in 1782. The first class graduated in 1788. It has a faculty of 203 members and 427 other instructors and assistants, a total of 630. Two years of collegiate work are required for admission. The accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$420, plus \$5 the first year for matriculation. The registration for 1943 was 526, graduates, 132. The present session began January 3, 1944 and will end September 25, 1944. The subsequent session begins October 2, 1944. The Dean is C. Sidney Burwell, M.D.

TUFTS COLLEGE MEDICAL SCHOOL, 416 Huntington Avenue—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. Coeducational since 1894. It has a faculty of 107 professors and 322 assistant lecturers and others, a total of 429. Four academic years of college study are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The total fees for each of the four years respectively, are \$512, \$507, \$507 and \$517. The registration for 1943 was 414, graduates, 98. The present session began Jan. 3, 1944 and will end September 1944. The subsequent class will begin Oct. 2, 1944. The Acting Dean is Dwight O'Hara, M.D.

MICHIGAN

Ann Arbor

UNIVERSITY OF MICHIGAN MEDICAL SCHOOL—Organized in 1850 as the University of Michigan Department of Medicine and Surgery. The first class graduated in 1851. Present title assumed in 1915. Coeducational since 1870. It has a faculty of 28 professors, 19 associate professors, 31 assistant professors, 89 assistants, instructors and lecturers, a total of 167. The entrance requirements are ninety semester hours. An accelerated program has been adopted involving the admittance of a class annually and the graduation of a class every nine months. The fees average \$250 per academic year, for nonresidents \$400 a year. The registration for 1943-44 was 535, graduates, 118. The last freshman class began Nov. 1, 1943 and ended July 22, 1944. The next freshman class will begin Oct. 30, 1944. The Dean is A. C. Furstenberg, M.D.

Detroit

WAYNE UNIVERSITY COLLEGE OF MEDICINE, 1516 St Antoine Street—Organized as the Detroit College of Medicine in 1885 by consolidation of the Detroit Medical College (organized in 1868) and the Michigan College of Medicine (organized in 1879). Reorganized with the title of Detroit College of Medicine and Surgery in 1913. The first class graduated in 1869. In 1918 it became a municipal institution under the control of the Detroit Board of Education. In 1934 the name was changed by action of the Detroit Board of Education to Wayne University College of Medicine, as a part of the program of consolidation of the Detroit city colleges into a university system. Coeducational since 1917. Entrance requirement is 60 semester hours from an accredited college or university for the duration of the war. The faculty consists of 46 professors, 302 lecturers and others, a total of 348. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$325 for Wayne County residents, and for nonresidents, \$425. The registration for 1943 was 260, graduates 58. The present session began January 3, 1944 and will end September 28, 1944. The subsequent session will begin October 2, 1944. The Dean is Edgar H. Norris, M.D.

MINNESOTA

Minneapolis

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL, Zone 14—Organized in 1883 as the University of Minnesota College of Medicine and Surgery, reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged. Present title in 1913. Coeducational since organization. The faculty includes 219 professors, of whom 82 are on full time appointment and 137 on part time, and 152 instructors. 38 of whom are on full time appointment and 114 on part time, a total of 371. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. The entrance requirements are three years of university work, which must include six semester credits of rhetoric, eight semester credits of physics, thirteen credits of general chemistry, qualitative and quantitative analysis, organic and physical chemistry, eight credits of general zoology and genetics and eugenics, four credits of general psychology, and a reading knowledge of scientific German, with a "C" average in all subjects and in the sciences. For the duration of the war entrance requirements have been reduced to two years of college work, and physical chemistry, genetics and eugenics, psychology, and German may be waived by the admission committee. Students are required to meet the requirements for a degree of B.S. or B.A. before receiving the degree of Bachelor of Medicine (M.B.), which is granted at the end of the course. The M.D. degree is conferred after a year of intern work, of advanced laboratory work, or of public health work has been completed. Total fees are \$252 per academic year for residents and \$477 for nonresidents. The registration for 1943 was 494, graduates, 108. The academic year 1944 began Jan. 4, 1944 and will end Aug. 26, 1944. The subsequent class will begin October 2, 1944. The Dean is Harold S. Diehl, M.D.

MISSOURI

St. Louis

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, 1402 South Grand Boulevard, Zone 4—Organized in 1901 as the Marion Sims-Beaumont Medical College by union of Marion Sims Medical College, organized in 1890, and Beaumont Hospital Medical College organized in 1886. First class graduated in 1902. It became the Medical School of St. Louis University in 1903. The faculty is composed of 80 professors and 284 instructors and assistants, a total of 364. The completion of three years of college study is the minimum admission requirement but students presenting meritorious credits in excess of the minimum are accepted by preference. During the war period the minimal entrance requirements, however, are two years of college with 60 semester hours of credit. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$536 per academic year. The registration for 1943 was 477, graduates, 107. The present session began November 22, 1943 and will end for freshmen, sophomores and juniors on September 2, 1944 and for seniors on September 21, 1944. The subsequent session begins for freshmen on August 28, 1944, and for sophomores, juniors and seniors on September 5, 1944. The Dean is Alphonse M. Schwitalla, S.J., Ph.D.

WASHINGTON UNIVERSITY SCHOOL OF MEDICINE, Kingshighway and Euclid Avenue, Zone 10—Organized in 1842 as the Medical Department of St. Louis University. The first class graduated in 1843. In 1850 it was chartered as an independent institution under the name of St. Louis Medical College. In 1891 it became the Medical Department of Washington University. In 1899 it absorbed the Missouri Medical College. Coeducational since 1918. The faculty comprises 162 professors and 341 lecturers-instructors and others, a total of 503. For the duration of the war the entrance requirement has been reduced to two years of collegiate work. The B.S. degree in medicine is conferred at the end of the third or fourth year. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$396. The registration for 1943 was 397, graduates, 110. The present session began January 3, 1944 and will end Sept. 12, 1944. The subsequent session begins January 3, 1944 and will end Oct. 5, 1944. The Dean is Philip A. Shaffer, Ph.D.

NEBRASKA

Omaha

CREIGHTON UNIVERSITY SCHOOL OF MEDICINE, 306 North Fourteenth Street, Zone 2—Organized in 1892 as the John A. Creighton Medical College. The first class graduated in 1893. Present title in 1921. Coeducational since organization. It has a faculty of 79 professors and 76 instructors, lecturers and assistants, a total of 155. Sixty-four semester hours of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$376 per academic year and \$100 additional each year for students who had not taken the major part of their work at Creighton University. The registration for 1943 was 257, graduates 59. The present session began Jan. 4, 1944 and will end Sept. 22, 1944. The subsequent session will begin Sept. 28, 1944. The Dean is Charles M. Wilhelm, M.D.

UNIVERSITY OF NEBRASKA COLLEGE OF MEDICINE, Forty Second Street and Dewey Avenue, Zone 5—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. The instruction of the first two years was given at Lincoln and of the last two at Omaha until 1913, when the work of all four years was transferred to Omaha. Coeducational since 1882. The faculty is composed of 78 professors and 54 lecturers and instructors, a total of 132. Two years of collegiate work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The B.S. degree in medicine is conferred at the end of the second year. The fees average \$250 per academic year. The registration for 1943 was 340, graduates, 73. The present session began Jan. 3, 1944 and will end September 23, 1944. The subsequent session will begin October 2, 1944. The Dean is C. W. M. Poynter, M.D.

NEW YORK

Albany

ALBANY MEDICAL COLLEGE, 47 New Scotland Avenue—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. In 1915 Union University assumed educational control. Coeducational since 1915. The faculty is composed of 93 professors and 109 instructors, assistants and others, a total of 202. The requirement for admission is three years of college work. For the duration students who have completed two years of college and who have the proper specific qualifications will be admitted. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The fees average \$532 per academic year. The registration for 1943 was 170, graduates, 38. The present session began January 3, 1944 and will end September 23, 1944. The subsequent session will begin October 2, 1944. The Dean is R. S. Cunningham, M.D.

Brooklyn 2

LONG ISLAND COLLEGE OF MEDICINE, 350 Henry Street—Chartered in 1930, was originally organized in 1858 as The Long Island College Hospital. From the collegiate department the first class was graduated in 1860 and the last class in 1930. The first class of the Long Island College of Medicine was graduated in 1931. It is coeducational. It has a faculty of 104 professors, associate, assistant, clinical and assistant clinical professors, and 213 lecturers, associates, instructors, assistants, and others, a total of 317. For the duration of the war two years of collegiate work, including specified courses, are required for admission for men in the armed services, three years for civilians. The medical course covers four academic years but is being given in three calendar years for the duration of the war. The fees average \$610 per academic year. The registration for 1943 was 413, graduates, 91. The present session began Jan. 3, 1944 and will end September 28, 1944. The subsequent session begins Oct. 2, 1944. The President and Dean is Jean A. Curran, M.D.

Buffalo

UNIVERSITY OF BUFFALO SCHOOL OF MEDICINE, 24 High Street—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. Coeducational since organization. The faculty is composed of 127 professors and 191 associates, assistants and others, a total of 318. The minimum requirement for admission is two years of collegiate work including certain prescribed science subjects. An accelerated program has been adopted admitting a freshman class every nine months. The fees for the entire course are \$2,000. The registration for 1943-1944 was 295, graduates, 61. The present session for freshmen began April 3, 1944 and ends December 23, 1944. The subsequent session for freshmen begins January 2, 1945. The Dean is Edward W. Koch, M.D.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 630 West One Hundred and Sixty Eighth Street—The medical faculty of Columbia College, then known as King's College, was organized in 1767. Instruction was interrupted by the War of the Revolution. The faculty was reestablished in 1792 and merged in 1814 with the College of Physicians and Surgeons, which had received an independent charter in 1807.

In 1860 the College of Physicians and Surgeons became the Medical Department of Columbia College. This merger became permanent by legislative enactment in 1891. Columbia College became Columbia University in 1896. The medical school has been coeducational since 1917. The faculty is composed of 320 professors and 609 instructors, demonstrators and others, a total of 929. Two years of collegiate work are required for admission. During the war, the school will remain in session throughout the year and entering classes will be enrolled once a year. Fees average \$338 per academic year. The registration for 1943 was 466, graduates, 108. The present session began January 3, 1944 and will end September 28, 1944. The subsequent session begins October 2, 1944. The Dean is Willard C. Rappleye, M.D.

CORNELL UNIVERSITY MEDICAL COLLEGE, 1300 York Avenue—Organized in 1898. Coeducational since organization. First year teaching was given formerly to approximately one third of the class at Ithaca but in 1938 this division was discontinued and all instruction is now in New York City. The faculty is composed of 155 professors and 223 instructors, assistants and others, a total of 378. All students admitted are from approved colleges for premedical training. The requirement for admission is three years of college work. An accelerated program has been adopted whereby a class graduates every nine months. The fees average \$622 per academic year. The registration for 1943 was 319, graduates, 75. The present session began Jan. 3, 1944 and will end September 26, 1944. The subsequent session will begin September 28, 1944. The Dean is Joseph C. Hinsey, Ph.D.

NEW YORK MEDICAL COLLEGE, FLOWER AND FIFTH AVENUE HOSPITALS, 1 East 105th Street—Organized in 1838. Incorporated in 1860 as the Homeopathic Medical College of the State of New York. The title New York Homeopathic Medical College was assumed in 1869, the title New York Homeopathic Medical College and Hospital in 1887, the title New York Homeopathic Medical College and Flower Hospital in 1908, the title New York Medical College and Flower Hospital in 1936, the present title of New York Medical College, Flower and Fifth Avenue Hospitals, June 22, 1938. The first class graduated in 1861. Coeducational since 1919. Two years of college work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. It has a faculty of 105 professors and associate professors, 68 assistant professors, 303 lecturers and assistants, a total of 478. The fees average \$683 per academic year. The registration for 1943 was 373, graduates, 83. The present session began January 3, 1944 and will end September 28, 1944. The subsequent session begins October 2, 1944. The President and Dean is J. A. W. Hettrich, M.D.

NEW YORK UNIVERSITY COLLEGE OF MEDICINE, 477 First Avenue, Zone 16—The Medical Department of New York University (then called the University of the City of New York) was organized in 1841. In 1898 it united with the Bellevue Hospital Medical College organized in 1861, under the name of University and Bellevue Hospital Medical College. In 1935 the name was changed to New York University College of Medicine. Coeducational since 1919. The faculty is composed of 199 professors, associate, assistant, clinical, associate clinical and assistant clinical professors and 367 lecturers, instructors and others, a total of 566. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. Entrance requirements are two years of study in an approved college of arts and sciences. The fees average \$600 per academic session. The registration for 1943 was 521, graduates, 121. The present session began January 3, 1944 and will end September 28, 1944. The subsequent session will begin October 4, 1944. The Acting Dean is Donald Sheehan, M.D.

Rochester 7

UNIVERSITY OF ROCHESTER SCHOOL OF MEDICINE AND DENTISTRY, 260 Crittenden Boulevard—Organized in 1925 as the Medical Department of the University of Rochester. Coeducational since organization. The faculty is composed of 74 professors, 216 lecturers, assistants, instructors and others, a total of 290. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. For the duration of the national emergency, two years of collegiate work are required for admission. The fees average \$500 per academic year. The registration for 1943 was 257, graduates, 63. The present session began January 3, 1944 and will end September 23, 1944. The subsequent session will begin October 2, 1944. The Dean is George H. Whipple, M.D.

Syracuse 10

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE, 766 Irving Avenue—Organized in 1873, when the Geneva Medical College, chartered in 1834, was removed to Syracuse, under the title "The College of Physicians and Surgeons of Syracuse University." Present title assumed in 1875, when a compulsory three-year graded course was established. The first class graduated in 1873 and a class graduated each subsequent year. In 1889 the amalgamation with the university was made complete. Course extended to four years in 1896. Coeducational since organization. The faculty is composed of 62 professors and 188 associate and assistant professors, lecturers and instructors, a total of 250. Two years of a recognized college course are required for admission. An accelerated program has been adopted involving the completion of the four-year course in three years, admitting a freshman class every nine months. The fees average \$600 per academic year. The enrollment for 1943-44 was 194, graduates, 38. The present session for upper classmen began January 3, 1944 and will end September 1944 and for freshmen began April 1, 1944. The subsequent session will begin in January 1945 for first, second and third year students, October 1944 for fourth year students. The Dean is H. G. Wickkott, M.D.

NORTH CAROLINA

Durham

DUKE UNIVERSITY SCHOOL OF MEDICINE—Organized in 1925. The first class was admitted October 1, 1930. Coeducational. The faculty is composed of 13 professors and 141 associate and assistant professors, lecturers, instructors and assistants, a total of 154. The premedical requirement is three years of college work. The academic year consists of four quarters of twelve weeks each, which must be taken consecutively, with graduation in three calendar years. The B.S. degree in medicine may be conferred for special work after six quarters. Students are urged to spend three years in hospital or laboratory work after graduation and must give assurance satisfactory to the executive committee that they will spend at least two years. Active duty with the Army, Navy or Public Health Service can replace the second year. The fees are \$450 for each year of three quarters. The registration for 1943 was 286, graduates, 60. During 1944-1945 the quarters begin January 3, April 3, July 3, October 2 and end March 25, June 24, September 23 and December 23. The first year students were enrolled January 3, 1944. The next freshman class will be enrolled October 2, 1944. The Dean is Wilbur C. Davison, M.D.

Winston-Salem 7

BOWMAN GRAY SCHOOL OF MEDICINE OF WAKE FOREST COLLEGE—Organized in 1902 at Wake Forest as a school offering only the first two years of the curriculum. In 1941 the school was moved to Winston-Salem and expanded to a complete four-year medical school under its present name. Ninety semester hours of college work are required for admission. For the duration of the present war students may be admitted who have completed only sixty semester hours. The B.S. degree is given to those who on admission have completed ninety semester hours of academic work after the completion of the first year in the medical school. The next class will be admitted on September 27, 1944. The faculty numbers 119, 18 of whom are on leave of absence in active military service. Tuition for each academic session is \$450. Registration for the session 1943 was 161, graduates, 27. The present session began January 3, 1944 and will end September 25, 1944. The subsequent session will begin September 27, 1944. The Dean is C. C. Carpenter, M.D.

OHIO

Cincinnati

UNIVERSITY OF CINCINNATI COLLEGE OF MEDICAL, EDEN AND BETHESDA AVENUES—Organized in 1909 by the union of the Medical College of Ohio (founded in 1819) with the Miami Medical College (founded in 1852). The Medical College of Ohio became the Medical Department of the University of Cincinnati in 1896. Under a similar agreement, March 2, 1909, the Miami Medical College also merged with the University when the title of Ohio Miami Medical College of the University of Cincinnati was taken. Present title assumed in 1915. Coeducational since organization. Candidates for admission to the freshman class will be accepted in accordance with the Army and Navy plan for the training of medical students for the duration of the war. Liberal arts students of the University of Cincinnati may enroll for the seven-year combined liberal arts and medical program. The B.S. degree is granted on the joint recommendation of the faculties of the College of Liberal Arts and Medicine at the end of the first medical year. The faculty consists of 112 professors, associate and assistant professors, 350 instructors, etc., a total of 462. During the period of the war emergency the college will operate on an accelerated program. A new class will be admitted every nine months. Tuition is as follows for legal residents of Cincinnati: \$485 a year plus breakage fees (\$50 additional for those not legal residents). Each session will consist of thirty-six weeks of work and there will be a short recess between the major sessions. The registration for 1943 was 325, graduates, 74. The present session began Dec. 13, 1943 and will end August 25, 1944. The subsequent class will be admitted Sept. 5, 1944. The Dean is Stanley Dorst, M.D.

Cleveland 6

WESTERN RESERVE UNIVERSITY SCHOOL OF MEDICINE, 2109 Adelbert Road—Organized in 1843 as the Cleveland Medical College in cooperation with Western Reserve College. The first class graduated in 1844. The school assumed the present title in 1881. In 1910 the Cleveland College of Physicians and Surgeons was merged. Coeducational since 1919. The faculty includes 102 professors and 270 lecturers, assistants and others, a total of 372. The curriculum covers four scholastic years of 38 to 40 weeks each. During the war emergency, these are spaced so that the entire course will be completed in three calendar years. For the duration of the war, the entrance requirements have been reduced to two years of college work. The fees average \$529 per academic year. The registration for 1943 was 317, graduates, 66. The present session began November 22, 1943, and will end on August 26, 1944, for the first three classes, and on September 25, 1944, for the fourth year class. The subsequent session will begin August 28, 1944. Webster G. Simon, Ph.D., is Acting Chairman of the Administrative Committee.

Columbus 10

OHIO STATE UNIVERSITY COLLEGE OF MEDICINE, Neil and Eleventh Avenues—Organized in 1907 as the Starling Ohio Medical College by the union of Starling Medical College (organized in 1847 by charter granted by the State Legislature changing the name from Willow, Ohio Medical College, which was chartered March 3, 1834) with the Ohio Medical University (organized 1890). In 1914 it became an integral part of the Ohio State University with its present title. Coeducational since organization. The faculty consists of 99 professors, associate and

assistant professors, 120 lecturers, instructors and assistants, a total of 219, of whom 77 are on military leave. Three years of collegiate work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. Tuition fees average \$318 per academic year and \$150 additional for nonresidents. The registration for 1943 was 299, graduates, 66. The present session began Jan. 4, 1944 and will end Sept. 1, 1944. The subsequent session will begin Oct. 3, 1944. The Acting Dean is R. C. Baker, Ph.D.

OKLAHOMA

Oklahoma City 4

UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE, 801 East Thirteenth Street—Organized in 1900. Until 1910 gave only the first two years of the medical course at Norman, Okla., after which a clinical department was established at Oklahoma City by taking over the Medical School of Epworth University. The first class graduated in 1911. Coeducational since organization. A new medical school building and a second teaching hospital became available in 1928, and since September of that year the entire four-year course has been given in Oklahoma City. It has a faculty of 28 professors, 24 associate professors, 26 assistant professors and 120 associates, lecturers, visiting lecturers, instructors and assistants, a total of 198. Two years of college work are a prerequisite for admission during the war. The course covers four years of nine months each. An accelerated program was adopted beginning May 10, 1943 involving admission and graduation of a class every nine months. Fees \$50 maintenance and incidental fee per semester. Other annual course fees average \$128, \$90, \$53 and \$58, in the order given, beginning with the freshman year. For students not residents of Oklahoma there is a tuition charge of \$350 a year, plus laboratory and course fees as indicated for the different years. The registration for 1943 was 252, graduates, 51. The present session began January 5, 1944 and will end September 15, 1944. The next session will begin September 25, 1944 and end June 15, 1945. The Dean is Tom Lowry, M.D.

OREGON

Portland 1

UNIVERSITY OF OREGON MEDICAL SCHOOL, Marquam Hill—Organized in 1887. The first class graduated in 1888, and a class graduated each subsequent year except 1898. The Willamette University Medical Department was merged in 1913. Coeducational since organization. It has a faculty of 91 professors and 164 lecturers, assistants and others, a total of 255. Entrance requirements are 82 semester hours of collegiate work. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The total fees are, respectively, \$380, \$375, \$370 and \$376 for residents of Oregon, and \$60 a year additional for nonresidents. The registration for 1943 was 284, graduates, 63. The present session began January 3, 1944 and will end September 21, 1944. The subsequent session will begin October 2, 1944. The Dean is D. W. E. Baird, M.D.

PENNSYLVANIA

Philadelphia

THE HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF PHILADELPHIA, 233 North Fifteenth Street, Zone 2—Organized in 1848 as The Homoeopathic Medical College of Pennsylvania. In 1869 it united with The Hahnemann Medical College of Philadelphia, taking the latter title. Assumed present title in 1885. The first class graduated in 1849. Coeducational beginning with 1941-1942 session. Two years of collegiate work in an approved college of arts and sciences are required for admission. It has a faculty of 113 professors and 114 lecturers, instructors and others, a total of 227. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. Fees are, respectively, \$527, \$524, \$524 and \$547. The registration for 1943 was 521, graduates, 115. The present session began January 3, 1944 and will end September 14, 1944. The subsequent session will begin October 2, 1944. The Dean is William G. Schmidt, Ph.D.

JEFFERSON MEDICAL COLLEGE OF PHILADELPHIA, 1025 Walnut Street—Organized in 1825 as the Medical Department of Jefferson College, Canonsburg, Pa. It was chartered with its present title in 1838. Classes have been graduated annually beginning 1826. In 1838 a separate university charter was granted without change of title, since which time it has continued under the direction of its own board of trustees. It has a faculty of 92 professors, associate and assistant professors and 232 associates, lecturers, demonstrators and instructors, a total of 324. The bachelor's degree requirement for admission has been suspended for the duration. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The total fees for the current session are, respectively, \$505, \$490, \$480 and \$480. The registration for 1943-1944 was 570 graduates, 133. Registration for the present session is 590. The current session for freshmen sophomores and juniors extends from January 10, 1944 to September 11, 1944, for seniors from January 10, 1944 to September 22, 1944. The subsequent session will begin October 9, 1944. The Dean is William H. Perkins, M.D.

TEMPLE UNIVERSITY SCHOOL OF MEDICINE, 3400 North Broad Street, Zone 40—Organized in 1901. The first class graduated in 1904. Coeducational since organization. The faculty numbers 29 professors and 214 associates, assistants and others, a total of 243. An accelerated program

has been adopted involving the admittance and graduation of a class approximately every nine months. Two years of collegiate work are required for admission. The fees average \$492 per academic year. The registration for 1943 was 468, graduates, 117. The present session began January 3, 1944 and will end September 14, 1944. The subsequent session begins October 2, 1944. The Dean is William V. Parkinson, M.D.

UNIVERSITY OF PENNSYLVANIA SCHOOL OF MEDICINE, Thirty Sixth and Pine Streets—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772 and 1775-1779, inclusive. The original title was the Department of Medicine, College of Philadelphia. The present title was adopted in 1909. It granted the first medical diploma issued in America. In 1916 it took over the Medico-Chirurgical College of Philadelphia to develop it as a graduate school. Coeducational since 1914. The faculty consists of 134 professors, 140 associate and assistant professors and 450 lecturers, associates, instructors and others, a total of 584. Three years of collegiate work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The tuition fee is \$500 each year, with a deposit fee of \$15, a general fee including student health of \$15 and a matriculation fee of \$5. The registration for 1943 was 517, graduates, 130. The present session began January 3, 1944 and will end September 23, 1944. The subsequent session will begin October 2, 1944. The Dean is William Pepper, M.D.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA, Henry Avenue and Abbottsford Road, East Falls—Organized in 1880. Classes were graduated in 1882 and in all subsequent years except 1862. It has a faculty of 88 professors and 70 assistants, lecturers and others, a total of 158. At least three years of collegiate work are required for admission and candidates with a degree are given preference. The curriculum covers four years of eight and one-half months each. Total fees are \$500 yearly. The registration for 1943-1944 was 140, graduates, 21. The last session for freshmen and sophomores began September 1, 1943 and ended May 20, 1944, for juniors and seniors July 3, 1943 to March 16, 1944. The present session for fourth year students began April 24, 1944 and will end January 10, 1945, third year students entered July 10, 1944 and will finish March 24, 1945. For first and second year students the next session will begin September 2, 1944 and end June 2, 1945. The Dean is Margaret D. Craighill, M.D., who is on leave of absence for military service. The Acting Dean is Marion Lutz, Ph.D.

Pittsburgh

UNIVERSITY OF PITTSBURGH SCHOOL OF MEDICINE, Bigelow Boulevard—Organized in 1886, as the Western Pennsylvania Medical College, and in 1908 became an integral part of the University of Pittsburgh, removing to the university campus in 1910. The first class graduated in 1887. Coeducational since 1899. The faculty is composed of 30 professors and 370 associates, assistants and others, a total of 400. Entrance requirements are two years of collegiate work. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. The total fees are \$500 each year. The registration for 1943 was 376, graduates, 81. The present session began Jan. 3, 1944 and will end about Sept. 29, 1944. The subsequent session will begin Oct. 2, 1944. The Dean is William S. McElroy, M.D.

SOUTH CAROLINA

Charleston 16

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA, 16 Lacy Street—Organized in 1823 as the Medical College of South Carolina. The first class graduated in 1825. In 1832 a medical college bearing the present title was chartered and the two schools continued as separate institutions until they were merged in 1838. Classes were graduated in all years except 1862 to 1865, inclusive. In 1913, by legislative enactment, it became a state institution. Coeducational from 1895 to 1912, when privileges for women were withdrawn being restored in 1917. It has a faculty of 49 professors and 40 associates, instructors and others, a total of 89, of which 36 are on a full time basis. The accelerated program for war time operation has been modified to permit only one entering class in 1945 and thereafter continued so as to complete the four academic years in three calendar years. Two years of collegiate work are required for admission during the war, but normally this requirement is three years. The total fees are \$422 each year for residents of South Carolina and \$622 for nonresidents of the state. The registration for 1943 was 188, graduates, 43. The present session began January 3, 1944 and will end September 16, 1944. The subsequent class will begin October 2, 1944. The Dean is Kenneth M. Lynch, M.D.

TENNESSEE

Memphis 3

UNIVERSITY OF TENNESSEE COLLEGE OF MEDICINE, 874 Union Avenue—Organized in 1876 at Nashville as Nashville Medical College. First class graduated in 1877, and a class graduated each subsequent year. Became Medical Department of University of Tennessee in 1879. In 1909 it united with the Medical Department of the University of Nashville to form the joint Medical Department of the Universities of Nashville and Tennessee. This union was dissolved in 1911. The trustees of the University of Nashville by formal action of that board named the University of Tennessee College of Medicine as its legal successor. In 1911 it moved to Memphis, where it united with the

College of Physicians and Surgeons. The Memphis Hospital Medical College was merged in 1913. Lincoln Memorial University Medical Department was merged in 1914. Coeducational since 1911. The faculty includes 140 professors and 162 assistants, instructors and others, a total of 302. Two years of collegiate work are required for admission. The B.S. degree in medicine is conferred at the end of the second year. The fees are \$120 quarterly. For residents of the state the charge is reduced \$50 each quarter. The registration for 1943-1944 was \$65; graduates, \$2. During the academic year of 1944-1945 the quarters begin June 26, September 25, January 1 and March 26, and end September 16, December 16, March 24 and June 16. The Dean is O. W. Hyman, Ph.D.

Nashville

MEHARRY MEDICAL COLLEGE, Eighteenth Avenue North and Meharry Boulevard, Zone 8. (For Negro Youth).—This school was organized in 1876 as the Meharry Medical Department of Central Tennessee College, which became Walden University in 1900. First class graduated in 1877. Obtained new charter independent of Walden University in 1915. Coeducational since 1876. The faculty is made up of 49 professors and 30 instructors and lecturers, a total of 79. Two years' work in a college of liberal arts are required for admission. Tuition fees are, respectively, \$325, \$315, \$305 and \$315 each year. The curriculum covers four academic years of thirty-six weeks each. Registration for 1943-1944 was \$50; graduates, \$2. In September 1942, Meharry Medical College instituted the quarter system. Meharry initiated an accelerated schedule in July 1943. The present session began March 28, 1944 and will end December 17, 1944. The subsequent session begins December 27, 1944. The President is Edward L. Turner, M.D.; the Dean is Michael J. Bent, M.D.

VANDERBILT UNIVERSITY SCHOOL OF MEDICINE, Twenty-First Avenue South at Edgehill, Zone 4.—This school was founded in 1874. The first class graduated in 1875. Coeducational since 1925. The faculty numbers 255. For matriculation, civilian students must be graduates of collegiate institutions of recognized standing or seniors in absentia, who will receive the bachelor degree from their college after having completed successfully one year of work in the school of medicine. Army and Navy students will be accepted on completion of the Army or Navy premedical program. The course covers four academic years of nearly nine months each, but due to the accelerated program, the four year course is now completed in three calendar years. The fees average \$465 per academic year. The registration for 1943 was \$206; graduates, \$9. The present session began December 27, 1943 and will end September 11, 1944. The following session begins September 25, 1944. The Dean is Waller S. Leathers, M.D.

TEXAS

Dallas

SOUTHWESTERN MEDICAL COLLEGE OF THE SOUTHWESTERN MEDICAL FOUNDATION, 2211 Oak Lawn.—Organized 1943. The first class graduated March 20, 1944. Coeducational since organization. It has a faculty of 126 professors (including associate and assistant professors) and 60 instructors and assistants or a total of 186. The medical college is operated on an accelerated program offering three trimesters of eleven weeks each per academic year so that each beginning student graduates in three calendar years. The tuition fees average \$418 per academic year including hospitalization costs. It is planned to change the instruction fee to \$175 per trimester commencing January 2, 1945; all other fees with the exception of \$5.00 for breakage per academic year will be eliminated. Sixty semester hours are required for admission. Registration for 1943-44 was \$270; graduates, \$61. The present session began April 3, 1944 and will end December 18, 1944. The subsequent session will begin January 2, 1945. Plans at the present call for the acceptance of new students approximately every nine months after January 2, 1945. Thereafter it is planned to matriculate the next class October 1, 1946. The Dean of Faculty is Tinsley Harrison, M.D.; the Dean of Students is Donald Slaughter, M.D.

Galveston

UNIVERSITY OF TEXAS SCHOOL OF MEDICINE, 912 Avenue B.—Organized in 1891. The first class graduated in 1892. Coeducational since organization. It has a faculty of 72 professors (including associate and assistant professors) and 76 instructors and assistants, a total of 148. The Medical Branch is operating on an accelerated program offering four academic terms of nine months each for completion of the medical curriculum of thirty-six months. Seventy-two semester hours are required for admission. The fees average \$92.50 per academic year, including health fees for medical care and hospitalization. The registration for 1943 was \$401; graduates, \$87. The last freshman class was matriculated November 1, 1943. The freshman class matriculated June 28, 1944. The last class graduated June 24, 1944. The subsequent freshmen will matriculate in September or October 1945. The Dean is Chauncey D. Leake, Ph.D.

Houston

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 509 Lincoln Street, Houston.—Organized in 1900 at Dallas as the University of Dallas Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University. It acquired the charter of Dallas Medical College in 1904. The school was moved to Houston in 1943. Coeducational since organization. The first class

graduated in 1901. Entrance requirements are 72 semester hours of collegiate work. The course covers four years of eight months each. An accelerated program was adopted beginning July 12, 1943, involving the admittance and graduation of a class every nine months. The fees are, respectively, \$418, \$408, \$398, \$423. The registration for 1943-44 was \$129; graduates, \$16. The present session began March 27, 1944 and ends November 13, 1944. The subsequent session will begin November 20, 1944. The Dean is Walter H. Moursund, M.D.

UTAH

Salt Lake City

UNIVERSITY OF UTAH SCHOOL OF MEDICINE, University Street.—Organized in 1906. Coeducational since organization. Four year curriculum established March 1943 and is now in full operation. The first senior class will graduate September 6, 1944. During the national emergency an accelerated program has been adopted with the admittance of a new class every nine months. Three years of collegiate work are required for admission. The faculty is composed of 11 professors, 23 associate professors, 25 assistant professors, 31 instructors and 12 lecturers; a total of 102. The fees for each quarter are \$135; there is a nonresident fee of \$55 each year. The registration for the 1943 year was \$126. The present session began December 13, 1943 and will end September 2, 1944. The subsequent session will begin September 11, 1944. The Dean is A. Cyril Callister, M.D.

VERMONT

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE, Pearl Street, College Park.—Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. Coeducational since 1920. It has a faculty of 60 professors and 44 instructors, and assistants, a total of 104. Three years of college work are required for admission. An accelerated program has been adopted involving the admittance and graduation of a class every nine months. For residents of Vermont the tuition fee is \$100 each session. Nonresidents are charged an additional \$150 each session. A \$25 fee is charged for the doctor's degree. The registration for 1943 was \$142; graduates, \$33. The present session began January 3, 1944 and will end September 13, 1944. The subsequent session will begin September 25, 1944. The Dean is Clarence H. Beecher, M.D.

VIRGINIA

Charlottesville

UNIVERSITY OF VIRGINIA DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. Coeducational since the session of 1920-1921. An accelerated program has been adopted involving the admittance and graduation of a class approximately every nine months. It has a faculty of 49 professors and 46 lecturers, instructors, assistants and others, a total of 95. Two years of college work are required for admission. For residents of Virginia the total fees average \$388 per academic year. Nonresidents are charged an additional \$50 each year. The registration for 1943 was \$264; graduates, \$54. The present session began December 27, 1943 and will end September 14, 1944. The subsequent session will begin September 29, 1944. The Dean is Harvey E. Jordan, Ph.D.

Richmond

MEDICAL COLLEGE OF VIRGINIA, Twelfth and Marshall Streets.—Organized in 1838 as the Medical Department of Hampden Sydney College. Present title was taken in 1854. In 1913 the University College of Medicine was merged. In 1914 the North Carolina Medical College was merged. Coeducational since 1918. Classes were graduated in 1839 and in all subsequent years. It has a faculty of 97 professors and 170 lecturers, instructors and others, a total of 267. Of this group 11 professors and 79 lecturers, instructors and others are on military leave. Two years of collegiate work are required for admission. An accelerated program has been adopted involving the admission and graduation of a class approximately every nine months. Fees average \$384 per academic year. Nonresidents are charged an additional \$125 each year. The registration for 1943 was \$111; graduates, \$74. The present session began December 30, 1943, for first year students; January 3, 1944 for all other students and will end September 23, 1944. The subsequent session will begin October 4, 1944, for first year students; October 9, 1944, for all other students. The Dean is J. P. Gray, M.D.

WISCONSIN

Madison 6

UNIVERSITY OF WISCONSIN MEDICAL SCHOOL, 418 North Randall Avenue.—Organized in 1907. Gave only the first two years of the medical course until 1925, when the clinical years were added. Coeducational since organization. The requirement of three years of collegiate

work for admission has been reduced to two years for the duration. Beginning July 1, 1943, a class was admitted every nine months. An accelerated program has been adopted permitting the completion of four years of academic work in three calendar years. It has a faculty of 64 professors and 67 lecturers, instructors and others, a total of 131. The fees average \$206 per academic year. An additional fee of \$200 each year is charged nonresidents. The registration for 1943-1944 was 265, graduates, 57. The present session for freshmen began April 1, 1944 and the following session will begin January 1, 1945. The Acting Dean is Walter J. Meek, Ph.D.

Milwaukee

MARQUETTE UNIVERSITY SCHOOL OF MEDICINE, 561 North Fifteenth Street—Organized in December 1912 by the merger of the Milwaukee Medical College and the Wisconsin College of Physicians and Surgeons. Coeducational since organization. It has a faculty of 192. Three years of collegiate work are normally required for admission. During the duration students are admitted in accordance with the prescribed Army and Navy programs. The accelerated program includes three semesters each calendar year, an equivalent of four years of eight and a half months each in three calendar years. The fees average \$450 per academic year. The registration for 1943 was 347 graduates 70. The last session began November 1, 1943. The present session began July 31, 1944. The Dean is Eben J. Carey, M.D.

CANADA

Alberta

UNIVERSITY OF ALBERTA FACULTY OF MEDICINE, Edmonton—Organized in 1913. Coeducational since organization. Has given the complete six-year medical course since 1924. New course—three years premedical, four years medicine, one year undergraduate internship for medical degree—has been offered beginning with the session 1942-1943. The faculty includes fifteen full time and sixty-nine part time professors, instructors and assistants and others, a total of eighty-four, of whom twenty are absent on war service. Tuition for the first and second years is \$255, for the third and fourth years \$265 and for the fifth and old sixth year \$263. The registration for 1943 was 151, graduates 35. The present session (accelerated) including only the 3rd, 4th and old 6th years began on June 1st 1944 and will end on December 31st, 1944. The following session (regular) will open on September 28th, 1944, for the 1st and 2nd years (not accelerated) and in February 1945 (accelerated) for the 4th and 5th years. The Dean is Allan C. Rankin, M.D.

Manitoba

UNIVERSITY OF MANITOBA FACULTY OF MEDICINE, Bannatyne Avenue, Winnipeg—Organized in 1883 as Manitoba Medical College, first class graduated in 1886, and a class graduated each subsequent year. The college transferred all its property to the University of Manitoba in 1919 and assumed the present title. Coeducational since organization. The faculty includes 36 professors and 103 instructors and assistants, a total of 139. Matriculation requirements include two years of collegiate work in the faculty of arts and science of a recognized university. An accelerated program was adopted but was discontinued with class entering in fall of 1943. The course extends over four years of eight months each and a hospital internship. The fees average \$254 yearly. The registration for 1943-1944 was 229, graduates 61. The last class for freshmen began August 21, 1943. The subsequent session begins for first and second years, September 1, 1944, third year began January 3, fourth year, January 17, and will end April 1945. September 30, 1944, and October 21, 1944. The Dean is A. T. Mathers, M.D.

Nova Scotia

DALHOUSIE UNIVERSITY FACULTY OF MEDICINE, Morris Street, Halifax—Organized in 1867. Incorporated as the Halifax Medical College in 1875. Reorganized as an examining faculty, separate from the Halifax Medical College, in 1885. In 1911, in accordance with an agreement between the Governors of Dalhousie University and the Corporation of the Halifax Medical College, the work of the latter institution was discontinued and a full teaching faculty was established by the university. First class graduated in 1872. Coeducational since 1871. It has a faculty of 45 professors and 34 demonstrators, lecturers and others, a total of 79, 14 of whom are in active service and are on leave for the duration. Requires for matriculation two years of arts. The regular medical course covers four years and a hospital internship of one year. Beginning in 1942 the last three years of the medical course were given under the accelerated plan. This was accomplished eliminating holidays, the content of the course being practically the same. The final year internship was reduced to eight months. On January 6, 1944, Faculty decided to discontinue acceleration. The last two years, that is one graduating in May, 1944 and the present fourth year were conducted on the accelerated plan. All other years will be conducted under the old schedule. The fees average \$317 yearly, \$250 additional registration fee payable by students outside the British Empire. The last freshman class began September 14, 1943 and ended May 16, 1944. The subsequent freshman class will begin September 1944. The registration for 1943-1944 was 169, graduates, 36. The Dean is H. G. Grant, M.D.

Ontario

QUEEN'S UNIVERSITY FACULTY OF MEDICINE, Kingston—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty numbers 63. Fees for the first year amount to \$231, and for the following years \$253. The course covers six years of thirty teaching weeks. An accelerated program has been adopted, and is in effect for all years except the first which has returned to the normal course. Freshmen will be admitted annually. Registration for 1943-1944 was 272, graduates, 47. The last session for freshmen began September 27 1943 and ended April 30, 1944. The next session begins for first, second and fifth year students on September 25, 1944, for fourth year students on January 8 1945, for sixth year students on April 30, 1945, and for third year students in September, 1945. The last Convocation was held on May 4, 1944, and another class will graduate in February, 1945. The Dean is G. Spencer Melvin, M.D.

UNIVERSITY OF TORONTO FACULTY OF MEDICINE, Toronto—Organized in 1843 as the Medical Faculty of King's College. Abolished in 1853. Reestablished in 1887. In 1902 it absorbed Victoria University Medical Department, and in 1903 it absorbed the Medical Faculty of Trinity University. Coeducational since 1903. The B.Sc. (Med.) degree is conferred at the end of the third or sixth year. It has a faculty of 77 professors and 336 (including 86 on leave of absence for the duration of the war) lecturers, associates and others, a total of 413. The fees are \$240 for the first year, for the second \$315, \$315 for the third year, \$340 for the fourth and fifth years and \$368 the sixth year. The registration for 1943-1944 was 772, graduates, 107. The last freshman class began September 28, 1943 and ended May 6, 1944. The next first year course begins September 26, 1944 and ends May 5, 1945. Students in the final year graduated May 5, 1944 and will graduate every eight months thereafter. The Dean is W. E. Gallic, M.D.

UNIVERSITY OF WESTERN ONTARIO MEDICAL SCHOOL, Ottawa Avenue, London—Organized in 1881 as the Western University Faculty of Medicine, first class graduated in 1883, and a class graduated each subsequent year. Present title in 1923. The medical school has been under the control of the Board of Governors of the University of Western Ontario since 1913. Coeducational since 1913. The faculty numbers 101. The normal course of study covers five years of ten months each. The total fees to residents of Canada for the last four years respectively are \$356, \$356, \$352 and \$360, nonresidents are charged \$646, \$646, \$642 and \$650 for each of the last four years. The registration for 1943-1944 was 201, graduates 31. The last session for freshmen began September 20, 1943 and ended May 1944. The next session begins for all years September 5, 1944, and ends June 16, 1945. The Dean is F. J. H. Campbell, M.D.

Quebec

MCGILL UNIVERSITY FACULTY OF MEDICINE, 3640 University Street, Montreal—Founded in 1823 as Montreal Medical Institution, became the Medical Faculty of McGill University in 1829, first class graduated under the university auspices in 1833. No session between 1836-1839, owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop's College. Coeducational since 1919. Three years of collegiate work are required for admission. An accelerated program has been adopted for the upper classes. The faculty consists of 82 professors and 204 lecturers and others, a total of 286. The total fees for each of the four medical years are \$391 plus \$100 for non-British subjects. The registration for 1943-1944 was 409, graduates, 97. The present session began for sophomores June 7, juniors February 17 and seniors May 6, 1943. Freshmen will enroll September 5, 1944. The next class will graduate July 31, 1945. The Dean is J. R. Fraser, M.D.

UNIVERSITY OF MONTREAL FACULTY OF MEDICINE, 2900 Mount Royal Boulevard, Montreal—Organized in 1843 as the Montreal School of Medicine and Surgery. In 1891, by Act of Parliament, the Medical Faculty of Laval University (organized in 1878) was absorbed. Present name by Act of Parliament in 1920. A class was graduated in 1843 and each subsequent year. Coeducational since 1925. The faculty numbers 150. The requirements for admission are: First, a B.A. degree (or its equivalent), Second, one year premedical in the faculty of pure sciences (or an entrance examination on the premedical subjects). An accelerated program has been adopted. An internship is required for graduation. The fees average \$235 yearly. The registration for 1943-44 was 298, graduates, 52. The present session for juniors and seniors began February 1, 1944, and will end September 30, 1944. Freshmen and sophomores will enroll September 18, 1944, and will complete the year May 31, 1945, there is no accelerated course for them, nor for those of the subsequent years. The Dean is Albert LeSage, M.D.

LAVAL UNIVERSITY FACULTY OF MEDICINE, Quebec—The Quebec School of Medicine, organized in 1848, became in 1852 the Laval University Faculty of Medicine, first class graduated in 1855, and a class graduated each subsequent year. An accelerated program was adopted in 1942 on account of the war. The faculty numbers 93. The fees for each of the medical years are \$200 for residents of Canada. Nonresidents are charged an extra fee of \$200 each year. The premedical requirement is a B.A. degree or its equivalent. The registration for 1943-1944 was 416, graduates, 57. The last session began September 15, 1943 and ended May 20, 1944. The next class will graduate in June 1945. The subsequent session will begin September 12, 1944. The Dean is Charles Vézina, M.D.

APPROVED SCHOOLS OF THE BASIC MEDICAL SCIENCES

ALABAMA

University (Tuscaloosa)

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE—Organized in 1859 at Mobile as the Medical College of Alabama. Classes graduated in 1861 and subsequent years excepting 1862 to 1868, inclusive. Reorganized in 1897 as the medical department of the University of Alabama. Present title assumed in 1907, when all property was transferred to the University of Alabama. In 1920 clinical teaching was suspended and the medical school was removed to the university campus near Tuscaloosa. A four year medical school is being developed at Birmingham to be known as "The Medical College of Alabama." Dr. Roy R. Kraeche has been appointed as Dean in charge of developments at Birmingham. The present school of basic medical sciences will be maintained at the University until the medical building at Birmingham has been completed. Coeducational since 1920. Minimum entrance requirements are 96 semester hours. An accelerated program has been adopted and a new freshman class will be admitted approximately every nine months. The faculty includes 14 professors and 14 instructors, assistants, and others, a total of 28, of whom 7 are absent in the Armed Forces. The tuition fees are \$354 each academic year plus \$75 differential for nonresidents. The registration for 1943 was 108. The present session began Dec. 6, 1943, and will end Aug. 15, 1944. The subsequent session will begin Sept. 4, 1944. The Dean is Stuart Graves, M.D.

MISSISSIPPI

University

UNIVERSITY OF MISSISSIPPI SCHOOL OF MEDICINE—Organized in 1903. Coeducational since organization. A clinical department was established at Vicksburg in 1908 but was discontinued in 1910 after graduating one class. An accelerated program has been adopted and a new freshman class is admitted each nine months. Entrance requirement is three years of collegiate work or ninety semester hours of credit. The B.S. degree in medicine is conferred at the end of the second year. The faculty includes 9 professors, 2 assistant professors, 1 adjunct professor, 17 instructors, assistants and others, a total of 29. The total fees for the first year are \$375, and for the second year \$348. The registration for 1943 was 55. The last class began September 27, 1943 and ended May 29, 1944. The present session began May 31, 1944 and will end January 23, 1945. The subsequent session begins January 29, 1945. The Dean is J. B. Looper, M.D.

MISSOURI

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE—Organized at St. Louis in 1845, was discontinued in 1855 but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. Coeducational since 1872. An accelerated program has been adopted involving the admittance of a class every nine months. The faculty includes 23 professors and 19 instructors, lecturers and others, a total of 42. The entrance requirements are sixty semester hours of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. Total fees for the first year are \$266, for the second, \$224. The registration for 1943 was 80. The current session began December 27, 1943 and will end September 1, 1944. The subsequent session will begin September 16, 1944. The Dean is Dudley S. Conley, M.D.

NEW HAMPSHIRE

Hanover

DARTMOUTH MEDICAL SCHOOL—Organized by Dr. Nathan Smith in 1797. The first class graduated in 1798. It is under the control of the trustees of Dartmouth College. Courses of the third and fourth year were discontinued in 1914. The faculty consists of 22 professors and 14 instructors, a total of 36. Army and Navy premedical curricula accepted for admission. An accelerated program has been adopted admitting a freshman class approximately every nine months or eight months of actual teaching. Candidates for the A.B. degree in Dartmouth College may substitute the work of the first year in medicine for that of the senior year in the academic department. The tuition is \$450 for each year. The registration for 1943 was 48. The last session began October 31, 1943 and ended June 24, 1944. The present session began July 1, 1944. The Dean is John P. Bowler, M.D.

NORTH CAROLINA

Chapel Hill

UNIVERSITY OF NORTH CAROLINA SCHOOL OF MEDICINE—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a

department in Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. Coeducational since 1914. Three years of college work are required for admission. Certificates are awarded on the completion of two years' work in medicine. The faculty is composed of 20 professors, 14 instructors and 7 lecturers, a total of 41. The fees for each year are \$322.20 for residents, for nonresidents an additional fee of \$100. The school has gone on the accelerated schedule for the duration of the war. The registration for 1943 was 91. The present session began December 8, 1943 and will end September 9, 1944. The subsequent session will begin September 18, 1944. The Dean is W. Reece Berryhill, M.D.

NORTH DAKOTA

Grand Forks

UNIVERSITY OF NORTH DAKOTA SCHOOL OF MEDICINE—Organized in 1905. Offers only the first two years of the medical course. Coeducational since organization. Three years work in a college of liberal arts are required for admission. (For the duration of the war about two years as per Army and Navy plans.) The B.S. degree in combined arts medical course is conferred at the end of the second year. The faculty consists of 7 professors and 7 instructors, a total of 14. The fees are \$170 each year for resident students and \$340 for nonresidents. The registration for 1943-44 was 57. The present session began March 27, 1944 and ends Dec. 16, 1944. The subsequent session will begin January 2, 1945. The Dean is H. E. Trench, M.D.

SOUTH DAKOTA

Vermillion

UNIVERSITY OF SOUTH DAKOTA SCHOOL OF MEDICAL SCIENCES—Organized in 1907 as the University of South Dakota School of Medicine. Present title in 1937. Coeducational since organization. Offers only the first two years of the medical course. Two years work in a college of liberal arts are required for admission. Students who complete the third year of premedical work in the College of Arts and Sciences at the University of South Dakota may apply the work of the first year of medicine to the A.B. degree. The B.S. degree is conferred at the end of the second year on those students who do not hold a combination (Arts and Sciences and Medicine Course) A.B. degree. The faculty numbers 18. An accelerated program has been adopted involving the admittance of a class approximately every nine months. The tuition is \$150 each year for residents and \$255 for nonresidents. The registration for 1943 was 44. The present session began Dec. 13, 1943 and will end September 2, 1944. The subsequent session will begin September 11, 1944. The Dean is Joseph C. Oldmacker, M.D.

WEST VIRGINIA

Morgantown

WEST VIRGINIA UNIVERSITY SCHOOL OF MEDICINE—Organized in 1902, gives the first two years of the medical course, but agreement has been made for the transfer of 20 students each year to the Medical College of Virginia. Coeducational since organization. Entrance requirements are three years of collegiate work. The B.S. degree in medicine is conferred at the end of the second year. An accelerated program has been adopted involving the admittance of a class every nine months. Faculty numbers 24. Fees for residents of the state are respectively, \$255 and \$265, nonresidents, \$150 additional each year. The registration for 1943 was 55. The present session began December 27, 1943 and will end September 16, 1944. The subsequent session begins September 25, 1944. The Dean is Edward J. Van Lier, M.D.

CANADA

Saskatchewan

UNIVERSITY OF SASKATCHEWAN SCHOOL OF MEDICAL SCIENCES, Saskatoon—Organized in 1926. Coeducational. Offers the first two years of the medical course. An accelerated program has been adopted. Two years of collegiate work are required for admission. The B.A. degree is conferred at the end of the second year. The medical faculty includes 7 professors and 4 lecturers and assistants, a total of 11. The fees are \$150 for each year. The registration for 1943-44 was 46. The last session for freshmen began October 4, 1943 and ended May 12, 1944. The next session begins September 28, 1944 for the first year. The second year session begins May 30, 1944 and ends May 11, 1945. The second year session begins May 30, 1944 and ends May 11, 1945. The Dean is W. S. Lindsay, M.B.

CHALLENGES TO MEDICAL EDUCATION

The medical schools and their faculties have met the challenge of wartime conditions admirably, teaching more students in less time than formerly in the face of greatly depleted numbers of instructors. The devotion of faculty members who carried on the increased work under adverse conditions is highly commendable. In the period of demobilization to come, special consideration should be given to the preferential early release of physicians on medical school faculties so as to restore the quality of medical instruction to a higher level as soon as possible.

The studies carried out by the Committee on Postwar Medical Service and reported by Lieut. Col. Harold Lueth in this issue (page 1099) indicate the magnitude of the problem of providing further education for discharged medical officers. There were requests for additional postwar training from 796 of 1,000 officers replying to a questionnaire. Nearly 34 per cent requested courses of less than six months' duration. Nearly 46 per cent desired further work in hospitals for six months to three or more years. Provision of the requisite additional educational opportunities will require the concerted efforts of internship and residency hospitals, medical schools, medical societies, specialty boards and others. We owe this service to those medical officers whose education was interrupted by the war.

Numerous problems in undergraduate medical education also must be met. Wartime experiences in medical care for the armed forces and for civilians have accentuated the growing importance of certain expanding fields of medicine. Notable among these are neuropsychiatry, public health, industrial health, physical medicine and tropical medicine. The place of these in undergraduate and graduate medical education is considered by authorities in these fields in this issue (pages 1103 to 1109).

More material cannot be added to the undergraduate curriculum unless other subject matter is withdrawn. At many points a reduction of the content of "courses" not only would be possible but would improve the educational program. Vested interests of certain departments or faculty members, established by outworn tradition or the aggressive capturing of curricular time, must not be permitted to stand in the way of an improved curriculum which will more adequately prepare the student for the problems of today in medicine.

THE CIVILIAN DOCTOR'S RESPONSIBILITY

The physicians of the United States have an enviable record in the war. Those in the armed forces both by their quality and by their numbers have cooperated in the finest program of medical care ever developed for any army or navy. More than 55,000 physicians left their civilian positions, and those who remained at home took over most of the medical care that had been previously given by those entering the service. Theirs too has been a tremendous, back breaking undertaking. Each physician is caring for fifteen hundred instead of a thousand people on the average. Those who have gone from each community have been the healthiest portion of the populace, the physically qualified young men and women. For the civilian physicians remained those who were not physically qualified and therefore required more attention per capita than the group cared for by physicians prior to the war.

This load has resulted in an increase in morbidity and mortality in the medical profession. While some advantages, particularly increased income, accrued to these physicians, they have shortened their lives and impaired their health in meeting this extra task.

At present only a sufficient number of physicians remain in civil life to meet the needs of the civilian population, provided they are properly distributed. In an attempt to aid such proper distribution, the Procurement and Assignment Service of the War Manpower Commission limited recruiting in certain states and facilitated over three thousand three hundred relocations. However, perhaps as a result of what seems to be the impending end of conflict, a tendency has developed on the part of some physicians to move into other areas of practice or to enter postgraduate or other special training rather than to remain in their present essential job of meeting the needs of the community that depends on them for medical care.

The medical profession itself requested that a federal agency be set up by which the members could voluntarily supply the armed forces with necessary medical care and as a part of that federal program to continue minimal adequate care for the civilian population. If

now any appreciable number of physicians leave positions in which they are considered essential, the medical profession will fail in the second and equally important goal which was set for its attainment. Each physician who is in an essential position should remain in that capacity until present shortages of physicians can be relieved. The excellent record of the medical profession both in peace and in war should not be marred by any sudden exodus at this time to meet the call of greener interesting fields or more lucrative pastures.

DISEASE AND RACE

Studies of the relations between race and disease have not thus far yielded any results useful in the prevention or therapy of diseases. Such investigations have been limited largely to the compilation of statistical data covering the comparative incidence of certain disorders or dispositions to various diseases of endogenous or exogenous origin among the various races. Relatively little effort has been made to correlate such numerical facts with peculiarities and differences in the functional and anatomic constitution of different racial groups. This information would, of course, be distinctly valuable in determination of the endogenous factors that control the susceptibility or resistance of the individual to pathogenic agents and mechanisms.

European investigators have turned their main attention to the differences existing apparently in this respect between the Nordic, Slavic, Mediterranean and Jewish racial mixtures inhabiting Europe and North Africa. They noted, for instance, the higher frequency of cutaneous cancer among the fair skinned members of the Nordic race, the predominance of thalassemia among the inhabitants of the central and eastern parts of the Mediterranean basin and the greater incidence of lipoidoses, diabetes mellitus, vascular degenerative diseases, pentosuria and fibroids and cancers of the corpus uteri among the Jewish parts of the white race.¹ American observers confirmed these observations in studies on the white population of the United States and extended their investigations on American Negroes, Indians and Filipinos. The almost exclusive occurrence of sickle cell anemia among Negroes and a high incidence of malignant nephrosclerosis, atherosclerosis, hypertension, keloids, uterine fibroids and ovarian tumors among the members of this racial group has been recorded. On the other hand, the Negroes exhibited a low incidence of cutaneous cancer, dermatitis and coronary thrombosis in comparison to the white population.² American Indians and Eskimos have normally a lower blood pressure than the white race and they resemble in this respect other Mongoloid groups, such as Chinese, Japanese and Koreans. Fili-

pinos, however, behave in regard to blood pressure much like European and American white persons living in the tropics.

The present worldwide struggle has scattered American physicians all over the globe and brought them into intimate contact with members of practically all races. American scientists have therefore a unique opportunity for studying the relations that exist between race and disease. They may thereby contribute valuable data to the defective and often contradictory information existing on this matter. Military necessities which prescribe the enforcement of sanitary regulations and medical supervision of the native population of many foreign lands provide at the present time opportunities and conditions for such investigations which are not attainable when peacetime conditions again prevail. Special attention should be paid in such studies to the long range effects which hybridization exerts on the health and anatomic and mental constitution of the resulting racial mixtures. As racial interbreeding has been in recent years mainly the subject of social, economic and political considerations, it becomes an urgent necessity that reliable biologic facts on this important subject be obtained, which may influence the future of our national life.

Current Comment

NEW MEDICAL SCHOOLS

Within the past year three schools have been added to the list of approved medical schools maintained by the Council on Medical Education and Hospitals. The Southwestern Medical College of the Southwestern Medical Foundation is located at Dallas, Texas. Dr. Tinsley Harrison is dean of the faculties. The Bowman Gray School of Medicine has expanded from a school of the basic medical sciences to a four year medical school, located at Winston-Salem, N. C. Dr. C. C. Carpenter continues as dean. Under the deanship of Dr. A. Cyril Callister, the University of Utah School of Medicine, at Salt Lake City, has also developed a four year program. The University of Alabama has virtually completed arrangements for expansion to the four year status, employing the facilities of the Hillman and Jefferson hospitals in Birmingham. It is anticipated that junior instruction will commence about July 1945 under the direction of Dean Roy R. Kracke. Dr. Stuart Graves will continue as dean of the basic sciences. The Council on Medical Education and Hospitals is glad to encourage and assist well planned institutions in developing medical schools where the need exists; it must, however, discourage ill conceived ventures in medical education. New and more medical schools will not solve the problem of distribution of medical care. There is no assurance that more doctors will practice in rural communities if more doctors are produced. The rate of production of doctors and their adequate distribution are independent problems.

NECROPSIES IN INTERNSHIP HOSPITALS

Under wartime conditions, with staff shortages, efforts at maintaining an adequate necropsy percentage tend to lag in some hospitals. The Council on Medical Education and Hospitals is aware of these difficulties, yet its responsibility for maintaining educational standards remains. The Council cannot continue for approval hospitals which fail to maintain the required 15 per cent of necropsies or which are unable to correct deficiencies in necropsy performance within a reasonable time. The necropsy ratio of a hospital is recognized as one of the more reliable indexes of the quality of educational service in hospitals. This service is especially important now, since the curtailed internships must be made maximally valuable to house officers. To insure that post-mortem examinations are requested on all deaths, house officers should be required in each instance to file a report in the superintendent's office containing either a signed permit or a notation as to why the necropsy could not be obtained. This procedure has been extremely helpful in many hospitals, for it creates further interest among the medical staff and serves to stimulate the interns and residents to greater effort.

TEXAS CHIROPRACTIC ACT UNCONSTITUTIONAL

Since 1876 there has remained in the constitution of Texas a clause granting the legislature the right to pass laws prescribing the qualifications of practitioners of medicine coupled with a proscription that "no preference shall ever be given by law to any schools of medicine." The meaning of this proscription has been an issue in two important Texas cases. In one case, which arose a number of years ago, Texas osteopaths sought to compel the governing board of a municipal hospital to permit the use of its facilities by such practitioners. They relied in part on the constitutional proscription to support their case, which eventually reached the Supreme Court of the United States. The court held that the proscription had nothing whatever to do with the right of osteopaths to practice in municipal hospitals, and the right demanded was denied.¹ More recently, in 1943, Texas chiropractors were successful in securing the passage of legislation creating an independent board of chiropractors to examine and license applicants and prescribing qualifications to be possessed by persons desiring to practice chiropractic. Theretofore adherents of the cult were required to meet the standards applicable to all other practitioners. In other words, until 1943 Texas had a single standard of medical licensure. Chiropractor Halsted failed to obtain a license under the new act, and prosecution was instituted. He sought his release by writ of habeas corpus, asserting that the act was unconstitutional because of the provision in the Texas constitution. He was successful in convincing the court of the soundness of his contention. In an opinion delivered June 7, 1944 by the Commission of Appeals and subsequently approved by the Court of Criminal

Appeals,² it was pointed out that in enacting the chiropractic act the legislature had given preference to chiropractors over all others engaged in treating the human body for diseases and disorders because of the fact that the cultists were not required to have the same educational qualifications nor were they required, as a condition precedent to their right to treat patients, to pass a satisfactory examination on the same subjects that are required of all other practitioners. That the act violated the nonpreference clause of the constitution was held to be clear and, quoting from the opinion, "when the Constitution speaks, it is supreme. An enduring and lasting government requires that it so remain."

REORGANIZATION OF MEDICAL TRAINING IN GREAT BRITAIN

Word has been received from the British Information Services that the Interdepartmental Committee on Medical Schools has made the following recommendations: That every medical school should be an integral part of some university, and grants from public funds for its educational work should be received through the university; that there should be more full time appointments and salaries for clinical teachers, with an academic head for each clinical division; that postgraduate study should be encouraged as a feature of regular practice by refresher courses for general practitioners, along with regular association with hospitals and the work of specialists; that medical schools should have a triple function with regard to research: (1) to discover and train research workers, (2) to facilitate their work by good teaching staffs and (3) to house special research units. It is recommended that central health service councils be established with university representation on them, that nonteaching hospitals have access to teaching centers and that special centers maintain refresher courses for general practitioners.

SCHOOLS FOR X-RAY TECHNICIANS

Essentials of an Acceptable School for X-Ray Technicians were adopted by the House of Delegates of the American Medical Association at the recent annual session. These essentials were prepared by the Council on Medical Education and Hospitals with the advice of various organizations interested in the training of x-ray technicians. A survey of schools for x-ray technicians disclosed that six were fulfilling the essentials, sixty-three had minor deficiencies and sixty-two will require further reorganization to meet the present requirements. Each of the schools having deficiencies will be urged to comply with the essentials before the first list of approved schools for x-ray technicians is printed in THE JOURNAL. The Council will continue its work with the various schools engaged in the training of x-ray technicians and will give full assistance in the development of satisfactory training programs.

2. Ex parte W. B. Halsted (No. 22,775) decided June 7, 1944, Court of Criminal Appeals.

MEDICINE AND THE WAR

ARMY

BLIND YANKS TREATED AT ST. DUNSTAN'S

The first American casualty from Normandy was recently admitted at St. Dunstan's, famous British hospital and training center for the war blinded. Under the system of mutual aid, by which not only equipment but the brains and experience of Britain and America are pooled, it was agreed by the American and British governments that this unique eye hospital would receive American casualties from the European theater and treat and train them exactly as are British soldiers and airmen. The United States could similarly take care of British eye casualties from the Pacific area. Seven Americans have been admitted to St. Dunstan's to date. Some have now returned to America to continue treatment and training. Others have so taken to St. Dunstan's training and personnel that they have asked to stay in England until thoroughly rehabilitated and have been allowed to do so.

The most recent achievements in coordination between British and American services for the blind include the production of "talking books." These full length recorded novels, biographies and many other types are so made that the blind can confidently handle and play them. Like ordinary phonograph records except for the fact that they are very slow running, they must be played on a specially constructed machine. Thus technical coordination is essential in order for Britain and the United States to exchange recordings.

Britain has just begun making talking books for the Library of Congress and other distribution in America, and several copies of "Whereas I Was Blind," by Sir Ian Fraser, the personal story of the founder of St. Dunstan's, are now en route. St. Dunstan's finds that the blind especially like novels which have made popular plays and films, and American recordings of Daphne Du Maurier's "Rebecca" and Margaret Mitchell's "Gone With the Wind," on eight records, have recently arrived here. Richard Llewellyn's "How Green Was My Valley" is a popular British recording.

POSTWAR TRAINING OF MEDICAL CORPS OFFICERS

The Office of the Surgeon General of the Army has announced the appointment of a committee to formulate plans for postwar training of medical corps officers who will be separated from the military service at the end of the war. The committee consists of Brig. Gen. Raymond W. Bliss, chief of operations service, chairman; Brig. Gen. James S. Simmons, chief of preventive medicine service; Col. James R. Hudnall, chief of personnel service; Brig. Gen. Fred W. Rankin, director of surgery division; Brig. Gen. Hugh J. Morgan, director of medicine division; Col. Floyd L. Wergeland, director of training division; Col. William P. Holbrook and Lieut. Col. R. H. Meiling, representatives from the Army Air Forces; Col. R. B. Skinner, representative from the Army Ground Forces; George B. Darling, M.D., representative from the National Research Council.

ARMY NURSE CORPS ACQUIRES FULL MILITARY STATUS

Approximately 40,000 Army nurses have become officers of the Army of the United States, acquiring full military status for the first time since the Army Nurse Corps was founded in 1901 by an act of Congress. By the terms of an executive order signed by President Roosevelt, the entire personnel of the Army Nurse Corps has been moved bodily into the Army, with the same pay and prerogatives as other officers. Prior to passage of the bill signed by the President, June 22, and made fully effective July 12, Army nurses held what was known in

the Army as "relative rank," giving them subordinate status and limited military authority. Army nurses now have the same status as members of the WAC, who were also an army auxiliary when first organized. Commissions in their present grades will be issued to all members of the Army Nurse Corps under the provisions of the new executive order unless they expressly decline appointment. Female dietitians and physical therapy aides will have the same military status as nurses and will be commissioned similarly.

MAJOR MARGARET M. JANEWAY ASSIGNED TO NEW DUTIES

Major Margaret M. Janeway, who spent fourteen months in Italy and North Africa as physician for 1,800 members of the Women's Army Corps in that area, was recently assigned to duty as assistant to Major Margaret D. Craighill, director of the Women's Medical Unit, Office of the Army's Surgeon General, Washington, D. C. This unit develops policies concerning the medical care and welfare of women in the Army, including the thousands of nurses, dietitians and physical therapy aides, as well as the members of the Women's Army Corps. Dr. Janeway became a contract surgeon in 1942 and was assigned to the WAC. She was commissioned a first lieutenant in December 1942 and landed in Africa Jan. 26, 1943 with the first Women's Army Corps contingent to be sent abroad. At that time her charges numbered 190 women, carefully chosen from various sections of the United States. When she returned to the United States her responsibilities had been broadened to include all the members of the Women's Army Corps in North Africa and Italy. Dr. Janeway graduated from Columbia University College of Physicians and Surgeons in 1927.

UTILIZATION OF RECOVERED PSYCHONEUROTIC PATIENTS

Recovered psychoneurotic patients are given retraining by the Army so that they may be utilized for further service. Classification boards carefully review each man's record and indicate the degree and kind of service he is capable of performing. The Classification Board will be constituted only for the purpose of removing classification of restriction as regards mental state for the purpose of declaring an enlisted man to be qualified for full general duty. Assignments are governed largely by the geographic location in which the men desire to be stationed, and it is the responsibility of each installation to utilize the men in best possible manner considering their limitations as shown on W. D., A. G. O. form 20 and Disposition Board report included in records.

FOURTEEN SOLDIERS WHO VOLUNTARILY CONTRACTED SANDFLY FEVER FOR RESEARCH AWARDED MEDALS

The Legion of Merit was recently awarded to fourteen soldiers who volunteered to submit to experiments which greatly increased the knowledge of sandfly fever, a disease encountered by American fighting men in tropical and semitropical regions. The soldiers were all infected with the disease during the experiments. The fever was produced in some of the volunteers by small injections of blood from individuals who had it and in others by deliberate exposure to repeated bites of infected sandflies. The carrier is a fly about an eighth of an inch long, and it is only the female of the species which bites. The experiments disclosed that the virus causing the fever in the Middle East was the same as that contracted by our soldiers in Sicily.

ARMY AWARDS AND COMMENDATIONS

Captain William Allison Stem

Capt William Allison Stem, formerly of Fayetteville, N. C., and now a flight surgeon for the twelfth air force in the European theater, has been commended by his commanding officer. The commendation, in part, reads "Capt William Stem is commended for his exceptionally meritorious service as squadron flight surgeon during the Tunisian, Pantellerian, Sicilian and Italian campaigns from Nov. 12, 1942 to Jan 31, 1944. His ability to handle delicate situations has caused him to become the primary morale building factor in his organization." Dr Stem graduated from the University of Tennessee College of Medicine, Memphis, in 1936

Captain Joseph J. Nannariello

Capt Joseph J Nannariello, formerly of Hoboken, N J, was awarded the Silver Star Medal for administering first aid to nine Yanks wounded by enemy gunfire. Fighting in ravines at close quarters, the nine were felled by a burst of Jap fire. A call came for stretcher bearers, but Captain

Nannariello realized that moving the men to first aid stations would require considerable time and possibly be dangerous for the wounded men. Without hesitation he moved up and administered first aid. The citation states that "this was done within a few yards of the enemy position and with no protection or cover other than a thin fringe of trees and grass." Dr Nannariello graduated from Georgetown University School of Medicine, Washington, D C, in 1941 and entered the service in May 1942

Captain Mark W. Dick

The Bronze Star Medal was recently awarded to Capt Mark W. Dick, formerly of Grand Rapids, Mich., and was accompanied by the following citation "While enemy mortar shells exploded around him, Captain Dick ran 40 yards and crawled under a barbed wire entanglement to reach a seriously wounded soldier. Finding that the nature of the man's wounds made it impossible to move him to the protection of a pillbox, Captain Dick unhesitatingly exposed himself and stood in an upright position to administer medical treatment during the intense mortar barrage." Dr Dick graduated from the University of Michigan Medical School, Ann Arbor, in 1932 and entered the service May 6, 1942

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS,
DENTISTS AND VETERINARIANS

HOSPITAL STAFFS

The directing board of the Procurement and Assignment Service recently emphasized that hospitals will not have residents of matured experience if they do not make every effort to keep women or disqualified men on their staffs for longer periods of time, and if they do not do this they will find themselves in a situation which the Procurement and Assignment Service cannot correct for them. Some hospitals are saying that they cannot get physically disqualified residents. These hospitals, on the other hand, have never listed their names in THE JOURNAL as having vacancies. Experience indicates that this listing results in a large number of applications, which must be evaluated, but it is the only way in which physically disqualified house staff can be obtained, and it must be obtained as far as possible if any significant maturity of such staff is to exist.

Additional reasons for following the recommendation is the possibility that there may be slight increases in quotas of interns and corresponding decreases in quotas of residents for the period of July 1945 to March 1946. Present contracts for that period should be made flexible enough to arrange for some such change in quotas.

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service

(Continuation of list in THE JOURNAL August 12, page 1047)

COLORADO

Colorado Psychopathic Hospital Denver Capacity, 78, admissions, 884 Dr Charles A Rymer, Acting Director (fellowships—psychiatry)

MICHIGAN

Eloise Hospital and Infirmary (William J Seymour Hospital), Eloise Capacity, 6,432, admissions, 7,095 Dr Charley J Smyth, Medical Director (residents—surgery, medicine, eye, ear, nose and throat, September 1)

MINNESOTA

Asbury Hospital Minneapolis Capacity, 165, admissions, 5,316 Miss Lydia A Miller, Superintendent (interns, mixed residents)

PENNSYLVANIA

Fitzgerald Mercy Hospital, Darby Capacity, 191, admissions, 5,380 Sister Mary Lioba, Superintendent (3 interns, October 1).

MISCELLANEOUS

RAPID, SIMPLIFIED METHODS FOR
TREATING GONORRHEA WITH
PENICILLIN

Physicians of the U. S Public Health Service, Federal Security Agency, recently reported on the rapid, simplified methods for treating gonorrhea with penicillin, which require no hospital care for the patients and which can be used conveniently by physicians in private practice or by clinics. One schedule of five treatments can be completed in only seven and one-half hours, another requires additional treatment the morning of the second day. The use of either of these methods, or modifications of them, may make possible wider application of penicillin treatment to the problem of gonorrhea control in the national program to combat venereal diseases where time and circumstances do not permit the use of standard twelve to twenty-one hour treatment schedules. The new methods have been effective in almost as large a percentage of cases as the standard schedules.

The "outpatient" schedules of treatment were developed by Dr C J Van Slyke of the Public Health Service Venereal

Disease Research Laboratory, Staten Island, and Dr S Steinberg of the U S Marine Hospital, New York. The race of the patients, the length of time they had the disease and previous treatment with sulfonamide drugs apparently had no effect on the results of penicillin treatment. Many of the patients volunteered the information that a definite sense of well-being followed the injections of penicillin.

THE ASSOCIATION OF MILITARY SUR-
GEONS OF THE UNITED STATES

At the fifty-second annual meeting of the Association of Military Surgeons of the United States, to be held at the Hotel Pennsylvania, New York City, November 2-4, addresses will be made by the nation's three surgeons general, the chief of the Veterans Administration, the commanding general of the Second Service Command and New York City's mayor. Other features of the meeting will be forum lectures, discussion panels, military and commercial scientific exhibits and medical motion pictures. The arrangements are under the direction of Col.

Lucius A. Salisbury, president of the Association of Military Surgeons of the United States, and Col. Charles M. Walson, chairman of the convention program committee.

The forum lectures will cover war surgery, chemotherapy, communicable diseases, neuropsychiatry, medical problems in theaters of operation, dental rehabilitation and equine encephalitis. Topics for discussion panels, which will be integrated with the lectures, are "War Wounds, Burns and Fractures," "Neuropsychiatric Problems," "Treatment and Prevention of Venereal Diseases," "Penicillin and Sulfonamide Therapy," "Orthopedic and Reconstruction Therapy," "Neurosurgical Problems," "Tropical Diseases in the Army and Navy" and "Aviation Medicine."

DISTRICT OFFICES OF THE DIVISION OF NURSE EDUCATION

Dr. Thomas Parran, Surgeon General, U. S. Public Health Service, recently announced that district offices of the Division of Nurse Education, U. S. Public Health Service, are being opened in seven districts throughout the country. Where space permits, these offices will be located in the district offices of the U. S. Public Health Service. A nurse education consultant will be in charge of each district office. In given schools of nursing, Cadet Nurse Corps accounts will be verified by auditors from the district office. Representatives resident in the district offices will furnish publicity guidance and material for the recruitment of student nurses.

The first district office of the Division of Nurse Education was officially established in New Orleans at the U. S. Public Health Service District No. 4, 1307 Pere Marquette Building, 150 Baronne Street, with Miss Elsie T. Berdan, nurse education consultant, in charge.

The New York District No. 1 was opened July 17 at 119 West 57th Street. Miss Mary O. Jenny is nurse education consultant.

In Chicago District No. 3, the Division of Nurse Education office is located in the City Hall Square Building, 139 North Clark Street, and is under the supervision of Miss Jane E. Taylor, nurse education consultant.

The San Francisco office, in District No. 5, is at 1223 Flood Building, with Miss Lyndon McCarroll in charge.

Other Divisions of Nurse Education District offices will be established in the District of Columbia, Kansas City and Denver.

HOSPITAL PROJECTS RECOMMENDED IN TWENTY STATES

Hospital projects in twenty states to provide 16,000 additional beds, to cost \$70,000,000, have been recommended to the Federal Board of Hospitalization by the Veterans Administration. The new beds would include 5,000 for neuropsychiatric patients, 3,000 for tuberculosis victims and 8,000 for general medical and surgical cases. The announced program is the first in the \$500,000,000 hospital setup authorized in the "G.I. Bill of Rights" law. The new hospital facilities will be located in New Hampshire, Rhode Island, Delaware, Virginia, Florida, Michigan, Kentucky, Louisiana, Mississippi or Alabama, eastern Kansas or northern Missouri, eastern Montana or western North Dakota, Colorado, California, Texas, Washington, New York, Georgia, Ohio, Pennsylvania and Illinois.

DOCTORS USE OWN BLOOD TO SAVE WOUNDED SOLDIER

Two British army doctors each took a pint of blood from the other to save a seriously wounded soldier after the Germans had bombed a dressing station on the Normandy beach. The two physicians, Capt. D. A. Squire of Bristol and Capt. Hugh Conway of Beith, Scotland, had already sent for a fresh supply for their dwindling stock of plasma. Before it reached them, however, a bomb demolished the evacuation tent, killing some stretcher bearers and critically wounding others. There was no time to wait for the plasma, so the two doctors gave their own blood to one of the most badly wounded, thus saving his life.

PUBLIC HEALTH UNDER HITLER

NDZ of April 27, 1944 (Germany) reports that the new regulation concerning the period of service for RAD girls and the inspection which is at present being carried out provide an opportunity—a fact which will reassure many mothers of RAD girls—to draw attention to the measures which are being taken to safeguard the health of the RAD girls. The war has increased the scope of the RAD for girls on a scale such as even experts thought improbable. Work in the camps continues to consist in helping overburdened peasants' wives and mothers. The introduction of the Auxiliary War Service and the employment of RAD girls on air defense have placed yet greater emphasis on the girls' share in the war effort.

As the majority of the girls are unaccustomed to physical work and must be able to adapt themselves to camp life, definite standards must be applied in their selection. For this purpose the RAD has issued directives according to which service and labor qualifications are assessed. These directives are very helpful to the men and women doctors who carry out the inspection and the recruitment examinations. The camp doctor makes a thorough examination immediately on the girls' arrival at the camp, and the girls remain in the camp only if their health is altogether up to standard. Local general practitioners or those living nearby do duty as camp doctors. At the consulting hours and health rallies the camp doctor supervises the health of the girls. Physical defects are thus quickly recognized and remedied. Light cases receive treatment in the camp sick bay. The camp doctor is aided by a specially trained woman health assistant. All the camps are well equipped with medicaments and medical appliances.

Patients who suffer from a prolonged or more serious illness are taken to a hospital or district sick bay of the RAD for girls. The district sick bays have up to 100 beds; they have modern equipment and enable the women doctors of the RAD on duty there to use a variety of methods in examining and treating the girls. But the woman doctor in the RAD is mainly concerned with physical fitness. She is out to forestall illness and to increase performance by improving the general health of the girls. The RAD girls are trained to lead healthy lives. There are ample facilities for washing as well as shower baths; work, time off and sleep alternate suitably, food and clothing are appropriate, and the physical training is well planned. If RAD girls work outside the camp, the families to whom they go are first medically examined, so that here too there is no question of danger to the girls' health.

All these measures are of use only if the girls' minds too remain healthy. Girls who constitute a danger to the community in that respect are immediately removed. The responsibility of the RAD to the parents is too great to allow a few outsiders to jeopardize educational success. There is hardly a family which watches so carefully over the health of the girls as does the RAD. It spares no effort in seeing to the girls' health, and even anxious parents may rest assured that their daughter is well looked after. The RAD enjoys the cooperation of the entire medical profession and also trains its own women doctors in courses which are free of charge.

Pester Lloyd of April 18 (Hungary) states that, according to Laszlo Endre, the problem of doctors is a serious one. There are 13,000 doctors, including 4,000 Jews, 1,000 women doctors and 1,000 doctors who no longer practice. On principle, Jewish doctors are allowed to treat only Jewish patients, but this cannot be done in practice owing to the shortage of doctors.

The *Pariser Zeitung* of March 25, 1944 states that Dr. Grassot has made declarations to the press regarding the state of tuberculosis in France. In 1938 cases of tuberculosis amounted to 143 per 10,000 inhabitants, while in 1944 the number has risen to 170. This is due partly to undernourishment through the war and partly to psychologic causes, but in particular to the Anglo-American terror raids. In 1939 it was possible to accommodate 37,000 persons in sanatoriums, but recently the number of beds has proved insufficient. A number of spas are now to be turned into resorts for the treatment of tuberculosis.

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

Aug. 14, 1944.

Proposed Health Center for Nation's Capital

How to bring hospital facilities of the nation's capital up to the level of Baltimore, Pittsburgh and other cities in the United States is now occupying the attention of national and local officials here. House and Senate subcommittees on health and hospitals have proposed establishment of a vast health center on a 20 acre plot of land, with existing hospitals to be integrated, though retaining their independent status.

Meantime, a House committee has already reviewed the situation and concluded sittings with a request for further basic information, and today (August 14) a subcommittee of the Senate District Committee begins hearings on a bill which is designed to modernize completely existing hospital services.

The capital is now a city of hospital contrasts, with the great Navy Medical Center at Bethesda, Md., and Walter Reed General Army Hospital, serving the armed forces, but with only one strictly modern private hospital for civilian patients. That one up to date institution is relatively small and in a downtown section barring expansion. Not only has Washington inadequate and overcrowded civilian hospitals, according to Senator Millard E. Tydings (Democrat, Maryland), but 50 per cent of the patient population here is housed in buildings which are serious fire hazards. The hospital bill was introduced in the Senate by Senator Tydings, with Senator Theodore G. Bilbo (Democrat, Mississippi), and in the House by Representative Jennings Randolph (Democrat, West Virginia) and Representative Thomas D'Alesandro Jr. (Democrat, Maryland). Under the bill a hospital center would be established, and into it larger existing hospitals would be merged and other smaller hospitals could be affiliated, all on a voluntary basis. Senator Tydings said that these unusual merger features were the result of a six months study by a group of public spirited citizens, who

have made surveys, exchanged views and made a concerted effort to formulate the best plans for adequate and economically operated hospital facilities here.

The hospital center, as proposed, would not have more than 1,500 beds, with complete facilities for diagnosis and treatment in all specialties. Each merged institution could thus care for its own clientele, with major economies resulting from consolidation and coordination, sponsors submit. Participating hospitals would be permitted to retain their identities as corporations, safeguarding endowments and other resources as well as tradition and good will. Overall management would be vested in a joint administrative board. It is suggested that an ideal site would cover 20 acres, which should be close to transportation facilities. Possible locations have been surveyed by the National Capital Park and Planning Commission. A dozen with suitable acreage have been recommended.

Representative D'Alesandro has called on all federal and Washington local agencies to make an immediate survey of local postwar health aid and at an open hearing, as head of the House District Subcommittee on Health and Hospitals, he appealed for postwar improvement proposals from District of Columbia government, the District Health Department and the U. S. Public Health Service. He did not indicate at the hearing that a health center was proposed. District commissioner Guy Mason advocated rebuilding of Providence, Georgetown, George Washington and Garfield hospitals and modernization of almost all other private hospitals as a first step in providing adequate protection for the expanding metropolitan population. He based his recommendations on an independent survey made several years ago by Charles F. Neergaard, New York hospital consultant. Before the House subcommittee hearing Representative D'Alesandro had proposed that a gigantic health center be built here after the war, but inability of witnesses at the House subcommittee hearing resulted in the congressman's request for further basic information.

MEDICAL ECONOMIC ABSTRACTS

COMMUNITY HEALTH AND WELFARE EXPENDITURES IN WARTIME

Changes in community health and welfare expenditures in wartime, as described in a report of the Children's Bureau, show significant changes in several trends that have existed for a number of years.¹

The study covers twenty urban areas distributed throughout the United States. The choice of localities was influenced to some degree by the existence of social service agencies which would undertake the collection of data. The disappearance of unemployment and resulting higher standards of living, together with military operations, have brought about changes in organization and administration in some fields of public service.

Family welfare and relief decreased in twenty-six out of thirty areas and cost \$360,000,000 in 1940 and \$221,000,000 in 1942. "The outstanding increase in expenditures in this field of service was for the American Red Cross." The largest increase has been 20 per cent in health service. Other increases are in group work and leisure time activities 18 per cent, child welfare service 9 per cent and "planning, financing and coordinating services" 8 per cent.

"Health was the only major field of service in which increases occurred in every area." The increase in child welfare work was due directly to withdrawal of parents and others responsible for such care for military service and war production.

"Expenditures for health services were higher in 1942 than in 1940 in every area." The total increase was almost 170 million. There was also a very significant change in the source of funds.

"Increased ability of patients to pay for service affected significantly the volume of hospitalization and, hence, the expenditures of hospitals. In 1942 hospital expenditures comprised 84 per cent of the total expenditures for health services. Including fees from patients, total hospital expenditures advanced 23 per cent between 1940 and 1942. Expenditures excluding fees increased only 8 per cent. In 1942 many people were able to pay for hospitalization either through direct payment or through hospital insurance plans. More than 10 million persons in the nation were participating in some type of hospital prepayment insurance plan at the end of 1942, compared with about 6 million at the end of 1940. Because of hospital insurance and increased earnings, many people could afford to obtain medical treatment promptly, whereas in prior years their hospitalization had to be postponed or was not received at all.

"Increased ability to pay, rather than increased morbidity," caused an increase in hospitalization that often exceeded the capacity of existing hospitals. In services supported by government or philanthropy there was a general decline. This was especially true of clinics. The main increase of public expenditures occurred in the institutional care of tuberculous and mental patients.

"Payments from recipients of service were a more important source of funds in financing the health programs in the thirty areas than in financing any of the other major fields of service."

In general there was a decline in expenditures by the federal government and an increase in support from local agencies. Even within the local field "a drop in proportion of local tax funds and a rise in fees dominated the pattern of change shown in expenditures for clinic service, which is the health service accounting for the largest part of health expenditures other than those for hospital care."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ILLINOIS

Edwin Hamilton Honored.—The Kankakee County Medical Society gave a dinner in honor of Dr. Edwin S. Hamilton at the Kankakee Country Club, June 20, in appreciation of his many services to organized medicine. Guests at the dinner included officers of the Illinois State and Chicago medical societies. Dr. Hamilton was presented with a traveling bag.

Chicago

Loyola Alumni Meetings.—The Loyola University Medical Alumni Association will hold a dinner during the State Medical Society of Wisconsin meeting in Milwaukee, September 18. The dinner will be in the Pere Marquette Room of the Hotel Schroeder. Dr. George W. Leitch, Milwaukee, is chairman of the local arrangements committee and Dr. Charles E. Pechous, Kenosha, state counselor. The association will also hold a meeting during the Michigan State Medical Society meeting in Grand Rapids, September 28, in the Hotel Pantlind. Dr. Christian G. Krupp, Grand Rapids, is local chairman and Dr. Lawrence R. Banner, Kalamazoo, state counselor. The association will also hold a reunion during the Indiana State Medical Association meeting in Indianapolis, October 3. Dr. Frank B. Fisk, Indianapolis, is local chairman and Dr. Homer B. Gable, Monticello, state counselor.

Medical School Honors Graduating Class.—The University of Chicago School of Medicine will hold a banquet in honor of the 1944 graduating class in the Crystal Ballroom, Windermere East Hotel, August 31. Alumni are invited. Among the speakers at the dinner, at which Dr. Lester R. Dragstedt, professor of surgery, University of Chicago School of Medicine, will be the toastmaster, will be Brig. Gen. Percy J. Carroll, M. C., who will discuss "Medical Service in the Southwest Pacific Theater of War"; David Hellyer, president of the class of 1944, who will speak for the class; Dr. Victor Johnson, Secretary of the Council on Medical Education and Hospitals of the American Medical Association, and professorial lecturer in physiology, for the alumni, and Roland W. Harrison, Ph.D., acting dean, Division of Biological Sciences, for the faculty. Brigadier General Carroll will be introduced by Col. John R. Hall, M. C. A feature of the banquet will be the presentation of the year book, the first of its kind, which was started by the present class.

Mrs. Bevan's Will.—The will of Mrs. Anna L. Bevan, widow of Dr. Arthur Dean Bevan, disposes of \$550,000, most of which will go into a trust fund benefiting the Presbyterian Hospital of Chicago, where her husband was for many years chief surgeon. Mrs. Bevan died July 31. Three bequests to charity include \$10,000 to the Country Home for Convalescent Crippled Children, West Chicago, \$5,000 to the Visiting Nurse Association and \$5,000 to the Ridge Farm Preventorium of Lake Forest. In addition there is a provision for \$10,000 to set up the Arthur Dean Bevan Endowment Fund for the Hospital Association of Lake Forest, the income to be used perpetually for teaching and research in the hospital's surgery department. The residue of the estate, after other bequests, will approximate \$458,000 and will go into a trust fund with the First National Bank of Chicago as trustee, the income to go perpetually to the Presbyterian Hospital for teaching and research in surgery. After the death of one beneficiary of the will, the money provided will go to the Presbyterian Hospital. The trust also will be known as the Arthur Dean Bevan Endowment Fund.

IOWA

Personal.—Morningside College, Sioux City, recently conferred the honorary degree of doctor of science on Drs. Don H. O'Donoghue, Oklahoma City, and Archibald F. O'Donoghue, Sioux City. The degrees were bestowed by Dr. James H. O'Donoghue, Storm Lake, father of the two physicians.

Special Society Election.—Dr. Chester L. Putnam, Manchester, was chosen president-elect of the Iowa Public Health Association at its eighteenth annual meeting recently in Des Moines and Paul J. Houser, M.S., Des Moines, was installed as president. Hazel Roberts, R.N., Manchester, was named vice president and Dr. Carl F. Jordan, Des Moines, is secretary.

KENTUCKY

Memorial Issue for Dr. McCormack.—The *Kentucky Medical Journal* for August was designated the Arthur Thomas McCormack memorial number in honor of the late secretary of the state society and state health commissioner. The issue contains various tributes and eulogies in honor of the late physician. Dr. McCormack died Aug. 7, 1943.

LOUISIANA

Otto Schales Joins Ochsner Foundation.—Otto Schales, D.Sc., research associate in medicine and tutor in the biochemical sciences at Harvard Medical School and director of the clinical laboratories of the Peter Bent Brigham Hospital, Boston, has been appointed director of chemical research of the Ochsner Foundation and director of the biochemical laboratory at the Ochsner Clinic, New Orleans.

Special Society Election.—Dr. John R. Schenken, professor and head of the department of pathology and bacteriology, Louisiana State University School of Medicine, New Orleans, was elected president of the Louisiana Association of Pathologists at a meeting at the Charity Hospital, July 6, and Dr. Emma S. Moss, assistant professor of pathology and bacteriology at the medical school, was elected secretary-treasurer.

MASSACHUSETTS

Admission of Women Students at Harvard.—Women students will be admitted to Harvard Medical School, Boston, for the first time if the university's board of overseers sanctions a move by the Harvard Corporation on September 25, according to the *New York Times*. The medical school faculty voted to admit women last year, but the Harvard Corporation opposed the action. The corporation recently reversed its decision, and the matter now goes before the overseers, who are expected to grant approval, it was stated.

Medicolegal Conference and Seminar.—The Massachusetts Medicolegal Society in conjunction with the medicolegal departments of Harvard, Boston University and Tufts medical schools will hold an all day conference at the Mallory Institute of Pathology, Boston City Hospital, October 4. It will include lectures, demonstrations and informal discussions concerning many subjects in legal medicine, particularly stressing some of the more recent procedures. This meeting will be open to any registered physician, lawyer, police official, senior medical student or other medical investigator who may be interested and care to register. No limit in number has been made. There will be no fee for registration. While advance application is not essential, it would be helpful to those arranging the conference if notice of intention to attend is sent prior to October 1 to Dr. William H. Watters, department of legal medicine, Harvard Medical School, Boston. The Harvard Medical School, Courses for Graduates, with the cooperation of the medical schools of Boston University and Tufts College, offers a seminar in legal medicine, October 2-7, planned particularly for medical examiners and coroners physicians but open to any other suitable graduate of an approved medical school. The course will be practical rather than theoretical and will consist of necropsy demonstrations, technique and interpretation of laboratory tests, study of the day by day cases of a medical examiner, round table conferences and the many subjects now included in the widening field of legal medicine. In order that each participant may receive the maximum benefit, the enrolment has been limited to fifteen. For the seminar the fee is \$25. Application should be made on or before October 1 to Harvard Medical School, Courses for Graduates, 25 Shattuck Street, Boston 15.

MINNESOTA

Prosecution of Abortionists.—The Minnesota State Board of Medical Examiners reports that on July 6 Michael J. Koehler, a licensed chiropractor of Minneapolis, was sentenced to a term of one year in the Minneapolis Workhouse after pleading guilty to a charge of abortion. On July 8 Lillian Kruse Flick, Minneapolis, was sentenced to a term of two years in the Women's Reformatory at Shakopee following a similar plea to a similar charge. Mrs. Flick also pleaded guilty to having a prior conviction of a felony.

Personal.—Dr. Francis E. Harrington, Minneapolis, who has been acting superintendent of the Minneapolis General Hospital, has accepted the position on a conditional basis for the duration of the war, pending the appointment of a full time superintendent. Dr. Harrington recently retired as health commissioner of Minneapolis. Dr. Herbert B. Aitken was

recently honored at a dinner given by the community of Le Center, where he had been practicing for fifty years; he was presented with a purse to cover expenses of a trip to his native England and a plaque carrying the inscription "in appreciation of fifty years of faithful service as family doctor in Le Center since April 9, 1894." He was given honorary membership in the American Legion post and life membership in the Le Center Community Club. Dr. Aitkens has been a member of the local school board for forty years and president for more than thirty.—Dr. David E. McBroom has resigned as superintendent of the Minnesota Colony for Epileptics, Cambridge, to accept a similar position at the State School and Home for Feeble-minded, Redfield, S. D.

Northern Minnesota Meeting.—The Northern Minnesota Medical Association will hold a scientific meeting and business session at the Androy Hotel, Hibbing, August 26, under the presidency of Dr. Herbert H. Leibold, Parkers Prairie. Among the speakers will be:

- Dr. Orwood J. Campbell, Minneapolis, Fractures of the Upper Extremities.
- Dr. Moses Barron, Minneapolis, Recent Advances in Medical Therapeutics.
- Dr. Lawrence E. Schneider, Duluth, Some Psychiatric Conditions Seen by the General Practitioner.
- Dr. Walter C. Alvarez, Rochester, Hints in Diagnosing Puzzling Abdominal Pain.

A luncheon session will be addressed by Dr. William A. O'Brien, Minneapolis; Dr. Alvarez; Dr. Willard L. Burnap, Fergus Falls, and Dr. Edward L. Tuohy, Duluth, and a clinical x-ray pathologic conference will be held by Dr. Tuohy, and Drs. John R. McNutt, George L. Berdez and Arthur H. Wells, Duluth. Dr. Richard N. Jones, St. Cloud, is secretary-treasurer of the association.

MONTANA

State Medical Appointments.—Dr. Edmund A. Welden, Lewistown, has been appointed to the Montana State Board of Medical Examiners to succeed Dr. Alonzo T. Munro, who has moved to the state of Washington. Dr. Charles J. Bresee, Great Falls, has been reappointed a member of the state department of public health, according to the *Journal-Lancet*.

Refresher Course in Obstetrics.—Dr. John L. Parks, chief of the department of obstetrics and gynecology, Gallinger Municipal Hospital, Washington, D. C., is giving a series of courses in obstetrics throughout the state under the auspices of the division of maternal and child health of the state department of public health in cooperation with the Medical Association of Montana. The local county medical society in the different centers chosen for the lectures is host to the meeting.

NEW YORK

Edward Bausch Dies.—Edward Bausch, LL.D., chairman of the board of Bausch & Lomb Optical Company, died in Rochester, June 30, aged 89.

Association of School Physicians.—Dr. Clarence A. Greenleaf, Olean, was recently elected president of the New York State Association of School Physicians; Dr. Edgar Bieber, Dunkirk, was reelected vice president and Dr. Clara Adele Brown, Oswego, secretary-treasurer.

Teaching Days on Poliomyelitis.—On August 17 a teaching day on poliomyelitis was conducted at Syracuse University College of Medicine at Syracuse, under the sponsorship of the university, the Cayuga, Cortland, Madison, Oneida, Onondaga and Oswego county medical societies, the state medical society and the state department of health. Among the speakers will be Drs. James E. Perkins, Albany, on "Epidemiology of Poliomyelitis"; John F. Landon, New York, "Clinical Features—Pathology, Diagnosis and General Treatment"; William B. Snow, New York, "Physical Therapy in the Acute and Convalescent Stages," and Halford Hallock, New York, "Orthopedic Measures." A similar program was held at the Cumberland Hotel, Plattsburgh, August 14, under the auspices of the Clinton, Essex, Franklin and St. Lawrence county medical societies, the state medical society, the state department of health and the Clinton County chapter of the National Foundation for Infantile Paralysis, at which the speakers were Drs. A. Clement Silverman, Syracuse; Arno D. Gurewitsch, New York, and R. Plato Schwartz, Rochester. An evening session was addressed by Dr. Perkins, who is director of the state division of communicable diseases. A similar program will be presented in Alexandria Bay, August 24, under the auspices of the Hamilton, Herkimer, Jefferson and Lewis county medical societies, the state medical society, the state department of health and the Jefferson County chapter of the National Foundation for Infantile Paralysis.

New York City

Grant for Mental Hygiene.—The Commonwealth Fund has given \$10,000 to the National Committee for Mental Hygiene to provide fellowships to train psychiatrists for work with children, it is reported. Both basic training and advanced study as well as refresher courses will be provided by fellowships.

Graduate Fortnight.—"Infections and Their Treatment" will be the theme of the graduate fortnight of the New York Academy of Medicine, October 9-20. The program will consist of morning panel discussions, afternoon hospital clinics, evening addresses and scientific exhibits and demonstrations. The speakers at evening sessions will include:

- Dr. Colin M. MacLeod, Factors Which Influence the Choice of Antibacterial Agents.
- Brig. Gen. Hugh J. Moran, M. C., Sulfonamides in the Control of Streptococcal Infections.
- Comdr. Alvin F. Coburn (MC), Mass Sulfadiazine Prophylaxis of Respiratory Diseases in the U. S. Navy.
- Dr. Francis G. Blake, New Haven, Conn., Rickettsial Infections in the Southwest Pacific Area.
- Brig. Gen. Stanhope Bayne-Jones, M. C., Infectious Hepatitis.
- Dr. Joseph E. Moore, Baltimore, Chemotherapy of Syphilis.
- John F. Mahoney, senior surgeon, U. S. Public Health Service, Chemotherapy of Gonorrhea.
- Dr. Russell L. F. Cecil, Chemotherapy in Acute Upper Respiratory Infections.
- Dr. William S. Tillett, Use of Penicillin in the Treatment of Pneumococcal Infections.
- Dr. John H. Dingle, director, commission on acute respiratory diseases, board for investigation of epidemic diseases, U. S. Army, Primary Atypical Pneumonia.
- Dr. J. Albert Key, St. Louis, Treatment of Osteomyelitis.
- Capt. Lewis K. Ferguson (MC), Treatment of Burns and War Wounds.
- Dr. Harrison F. Flippin, Philadelphia, Recent Developments in Sulfonamide Therapy.
- Dr. Charles A. Janeway, Boston, Use of the Immune Globulin Fraction of Human Plasma in Acute Infections.
- Dr. Wiley D. Forbes, Durham, N. C., Reactions of Tissues Following Infection and Their Place in an Environmental Conception of the Nature of Disease.
- Lieut. Comdr. Harold J. Harris (MC), Brucellosis (undulant fever) Problems of Diagnosis and Treatment.

The Ludwig Kast Lecture will be delivered by René J. Dubos, Sc.D., on "The Mode of Action of Antibacterial Agents" and the Carpenter Lecture by Dr. Thomas Francis Jr., Ann Arbor, Mich., on "Influenza—Methods of Study and Control." The panel discussions will be devoted to pneumonia types and their response to various forms of chemotherapy, treatment of syphilis and gonorrhea and treatment of infections of the eye, ear and upper respiratory tract.

NORTH CAROLINA

Personal.—Dr. James J. Croley, Plymouth, has resigned as head of the district health department serving Tyrrell, Hyde and Washington counties.—Dr. Ottis L. Ader, Walkertown, has been named director of the venereal disease clinic of the Durham City-County Health Department, succeeding Dr. Roy H. McDowell, Durham.—Dr. Robert B. C. Franklin, Mount Airy, has resigned as health officer of Surry County to enter military service.—Dr. James E. Hemphill has been appointed associate professor of radiology at the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, effective July 1.

Opening of Schools Delayed Because of Poliomyelitis.—On August 4 the executive committee of the state board of health passed the following resolution:

In view of the grave situation which exists in North Carolina because of the epidemic of poliomyelitis, of which there have been up to this time 453 cases reported in forty-eight counties since June 1, and which has resulted in twenty-one known deaths, it is the sense of this committee that the local boards of education and those charged with the administration of all private and parochial schools defer the opening of any and all such schools until September 18, and then only if the epidemic has subsided to such an extent as to permit their opening with safety.

The action was taken after consultation with Dr. James P. Leake, Washington, D. C., epidemiologist of the U. S. Public Health Service. A release from Dr. Carl V. Reynolds, Raleigh, state health officer, stated that in 1935 the poliomyelitis epidemic began in May and had subsided by September. However, this year the outbreak did not begin until June; July registered more cases than were reported in July 1935, and there is a possibility that August of this year will show a greater number of cases than August 1935, throwing the period of abnormal incidence into the school year. On August 5 poliomyelitis had been reported in four additional counties, all in the eastern part of the state, these counties being Hyde, Pitt, Beaufort and Bertie. Dr. Reynolds stated that everything humanly possible has been done to hospitalize every infantile paralysis case in the state. At the time of his report on August 5 there were more than 150 patients at the Hickory center, nearly 60 at Charlotte and about 50 at Gastonia, all of whom are being given care never before given anywhere

in the history of the disease. At the time of his report there was an estimated 90 per cent of the state's children under voluntary quarantine through the cooperation of parents in keeping their children at home.

NORTH DAKOTA

Special Society Election.—At the recent twenty-sixth annual meeting of the North Dakota Academy of Ophthalmology and Otolaryngology Dr. Wilbur L. Diven, Bismarck, was elected president, Dr. Clarence W. Robertson, Jamestown, vice president, and Dr. Albert E. Spear, Dickinson, secretary-treasurer, to succeed Dr. Frederick L. Wicks, Valley City, who resigned after holding the position for twenty-five years (THE JOURNAL, July 29, p. 921).

OHIO

Latin Americans at Health Museum.—Drs. Mario Quieroz, in charge of the federal health museum in Brazil, and Pedro B. de Araujo Penna, an officer of the National Public Health* Education Service of Brazil, are spending a number of weeks at the Cleveland Health Museum as interns, under the auspices of the Office of the Coordinator of Inter-American Affairs.

School and Community Health Education.—The Ohio Department of Education in cooperation with the Ohio Department of Health will conduct a school and community health education project throughout the state, beginning with the fall term in September. Financed by a grant from the W. K. Kellogg Foundation of Battle Creek, Mich., funds allotted to the state department of education are to be specifically expended for workshops, inservice training of teachers, health conferences, publications, outline of the course of study and the employment of a full time health education consultant to supervise the project on a state level. Main units to be included in the project are helping students to meet general health objectives, helping students to meet health objectives for special wartime services, family health, health agencies, community health, the function of the school health program and administration of the health education program.

Dr. Gerstenberger to Devote Full Time to Writing.—Dr. Henry J. Gerstenberger has been granted a leave of absence as director of the Babies and Childrens Hospital and director of pediatrics at Western Reserve University School of Medicine, Cleveland. Dr. John A. Toomey, clinical professor of pediatrics and contagious diseases at the medical school, will be acting director of the hospital and acting director of pediatrics at the medical school. He will also take over Dr. Gerstenberger's activities as administrator of the contagious division at City Hospital, Cleveland, where he is physician in charge of the division at the present time. The change will be effective August 26. Dr. Gerstenberger will devote the remaining years of his active career as professor of pediatrics at the medical school to publishing results of his extended researches and to do other writing. In making the announcement of the change Winfred G. Leutner, LL.D., president of Western Reserve, stated that Dr. Gerstenberger has been collecting photographs, roentgenograms, clinical records and scientific data, but the pressure of his many activities made it impossible for him to carry out his plans to prepare these for teaching and publication. It is hoped that he will soon be able to write the history of the Babies and Childrens Hospital and the development of preventive and social medicine in Cleveland.

PENNSYLVANIA

Personal.—Dr. George B. Woods, Washington, who is 93 years of age, is credited with being the oldest graduate of Waynesburg College. Dr. Wesley D. Richards, Bellevue, has been appointed a member of the state board for medical education and licensure. A dinner was given to Dr. Harry J. S. Keim, Catasauqua, recently, in recognition of his completion of fifty years in the practice of medicine.

Philadelphia

New Professor of Pharmacology.—Dr. Lloyd D. Seager has been appointed professor of pharmacology and toxicology at the Woman's Medical College of Pennsylvania to succeed Ben King Harned, Ph.D., who has joined the research staff of Lederle Laboratories, Inc., New York. Dr. Harned has held the position since 1935. Dr. Seager served as senior instructor in pharmacology at St. Louis University School of Medicine from 1934 to 1939 and has been assistant professor of pharmacology at the University of Tennessee College of Medicine, Memphis, since 1939. He graduated at St. Louis University in 1934.

SOUTH DAKOTA

State Medical Election.—Dr. William Duncan, Webster, was chosen president-elect of the South Dakota State Medical Association at its recent annual meeting and Dr. Daniel S. Baughman, Madison, was installed as president. Dr. Roland G. Mayer, Aberdeen, is the secretary.

TENNESSEE

Changes in Health Officers.—Dr. William O. Bingham, Roan Mountain, has resigned as health officer of Carter County. Dr. William B. Farris, Franklin, in charge of the Williamson County Health Unit, has accepted a similar position in Sumner County, effective June 1. Dr. William B. Camp has been appointed director of the Bedford-Marshall County Health District.

Society Observes Fiftieth Anniversary.—The Upper Cumberland Medical Society held its fiftieth annual meeting in Cookeville, June 27-28, under the presidency of Dr. Sam B. McFarland, Lebanon. Among the speakers were:

- Dr. Carl R. Crutchfield, Nashville, Management of Malignancies of the Colon and Rectum.
- Dr. Roscoe C. Gaw, Gainesboro, Some of the Common Emergencies in General Practice and Their Management.
- Dr. Edward D. Gross, Chestnut Mound, Pyelitis.
- Dr. Charles T. Lowe, Lebanon, Management of Abnormal Obstetric Cases.
- Dr. Thurman Shipley, Cookeville, Treatment of Varicose Veins and Ulcers by Sclerosis.
- Dr. William A. Howard, Cookeville, Differential Diagnosis in Gall-bladder Disease and Coronary Heart Disease.
- Dr. John T. Moore, Algood, Some Unusual Cases of Continued Fever.
- Dr. Joseph R. B. Branch, Macon, Ga., Medical Conditions in China and Japan.
- Major John R. Nerves—Not Psychoses.
- Dr. Thayer S. Management of Acute Intestinal Obstruction.
- Dr. Henry L. Douglass, Nashville, Prostatic Hypertrophy.
- Dr. Burnett W. Wright, Nashville, An Unusual Kidney Condition.

GENERAL

Society News.—The American Rheumatism Association has announced that its 1945 session will be held during the annual session of the American Medical Association in New York in June. The chairman of the program committee is Dr. Donald F. Hill, 4 East Congress Street, Tucson, Ariz. Dr. Loring T. Swain, 372 Marlborough Street, Boston, is the acting secretary of the American Rheumatism Association.

Infantile Paralysis Fund.—The National Foundation for Infantile Paralysis received in its 1944 March of Dimes celebrations the total of \$10,973,491, the greatest donation from the American public since the President's birthday celebrations were started. Last year's contributions totaled \$5,527,590. In an announcement to the press August 6 Mr. Basil O'Connor, president of the National Foundation for Infantile Paralysis, stated that the disease now is prevalent or threatening outbreaks in twelve states: North Carolina, Kentucky, New York, Louisiana, Pennsylvania, Virginia, Tennessee, Ohio, Michigan, Maryland, Mississippi and Indiana. To date this year the number of cases is bigger than during the comparable period of 1943, when the United States suffered its "third worst" recorded epidemic of infantile paralysis. Half the amount of funds raised annually is retained by the three thousand county chapters for aid to poliomyelitis sufferers; the rest is sent to the foundation for research, epidemic aid and education.

Mississippi Valley Meeting.—The tenth annual session of the Mississippi Valley Medical Society will be held at the Pere Marquette Hotel, Peoria, September 27-28. Speakers on the "all Chicago" program on Wednesday will include:

- Dr. Raymond B. Allen, Obligations of Practicing Physicians to Medical Education.
- Dr. Warren H. Cole, Appendicitis.
- Dr. Edward L. Compere, Treatment of Intertrochanteric Fractures of the Femur.
- Dr. Loyal Davis, Experiences as Consultant in Neurological Surgery in the European Theater of Operations.
- Dr. Newell C. Gilbert, The Clinical Use of Digitalis.
- Dr. Andrew C. Ivy, The Rationale of Tests of Liver Function.
- Dr. Eric Oldberg, Herniated Intervertebral Disks.
- Dr. David Slight, Psychiatric Problems in Veterans.
- Dr. Willard O. Thompson, The Fröhlich Syndrome.

Speakers on the "all St. Louis" program Thursday will include:

- Lieut. Comdr. Henry C. Allen (MC), Recent Advances in Laboratory Diagnosis.
- Dr. Hollis N. Allen, Curable Leukemia?
- Dr. Edwin C. Ernst, Diagnosis and Treatment of Cancer of the Cervix.
- Dr. Oswald P. J. Falk, Practical Points in Recognition and Management of Coronary Disease.
- Dr. George T. Gafney, Cancer of the Rectum.
- Dr. Louis H. Jorstad, Management of Lymph Nodes in Neck in Neoplastic Disease.
- Dr. Roland M. Klemme, Neurosurgical Aspect of Essential Hypertension.

Capt. Alphonse McMahon (MC), Medicine in the South Pacific.
Dr. Arthur Wright Neilson, The Use of Massive Arsenotherapy and Penicillin in the Treatment of Syphilis.
Dr. Carl A. Wattenberg, The Kidney and Hypertension.
Drs. Edward Massie, Raymond O. Muether and Robert A. Moore will participate in a round table discussion on hypertension. Speakers at evening sessions will include Frederick M. Gillies, general superintendent, Inland Steel Company, East Chicago, Ind., on "We Must Retain Free Enterprise"; Dr. Everett P. Coleman, Canton, Ill.; Dr. Maurice C. Hennessy, Council Bluffs, Iowa, and Dr. Arthur S. Bristow, Princeton, Missouri.

Changes in Status of Licensure.—At a meeting of the California Board of Medical Examiners in San Francisco, June 26-29, the following actions were taken:

Dr. Archibald A. Atkinson, North Sacramento, found guilty of violation of the business and professions code and placed on five years' probation without narcotic privileges.

Dr. Arthur Anson Bird, Oakland, found guilty of violation of the business and professions code and his license revoked.

Dr. Charles Bacon Boudwin, Los Angeles, found guilty of violation of the business and professions code (alleged illegal operation) and his license revoked.

Dr. Gustav Adolph D. Eisengraeber, Minneapolis, found guilty under the business and professions code and his license revoked.

Dr. George C. Esker Jr., Wilmington, found guilty of violation of the business and professions code and penalty deferred to the August meeting of the board.

Dr. Edward M. Lundegard, Oakland, found guilty of violation of the business and professions code (alleged aiding and abetting of unlicensed practitioner) and placed on probation for one year, with the proviso that he report at the June 1945 board meeting.

Dr. Frederick H. C. Olberg, Sacramento, found guilty of violation of the business and professions code and placed on probation for five years, without narcotic privileges.

Dr. George Edmund P. Walton, Oakland, found guilty of violation of the business and professions code (alleged aiding and abetting of unlicensed practitioner) and placed on probation for one year, with the proviso that he report at the June 1945 board meeting.

The Massachusetts Board of Registration in Medicine reports the following:

Dr. Perry C. Baird Jr., Boston, license revoked June 21 because of a mental condition.

The Pennsylvania State Board of Medical Education and Licensure recently took the following actions:

Dr. Ralph H. Armstrong, Peckville, license revoked because of his conviction in the courts of Lackawanna County for committing abortion.

Dr. Alexander J. P. Conlen, Allentown, license revoked for advertising.

The Kansas State Board of Medical Registration and Examination on June 8 took the following actions:

Dr. John C. Curtis, Kansas City, license revoked for conviction on a felony charge of narcotic violations.

Dr. Harold H. Theis, formerly of Norton, license revoked for morphine addiction; whereabouts unknown at present time.

Dr. Daniel R. Wilson, formerly of Kansas City, license restored.

LATIN AMERICA

Health Activities of Latin America.—*New Training Division of Inter-American Institute.*—A new training division in the Institute of Inter-American Affairs, created July 1, will administer the fellowship program of the food supply division as well as that of the health and sanitation division, according to the latter's *Newsletter* of July 19. The new division was formerly the professional training and health education section of the division of health and sanitation. Dr. Charles E. Shepard, formerly chief of the latter, has been made director of the professional training division, and Mr. Philip A. Hooker, formerly of the food supply division, has been appointed associate director. Health education activities will remain in the division of health and sanitation and will be administered by the medical section. The Institute of Inter-American Affairs has been assisting in the training of Latin American professional and technical personnel through the granting of fellowships for training in the United States and by the Inter-American Cooperative Health Services in the various American republics through a number of local training projects. On Oct. 8, 1942 the program started, when the board of directors of the Institute of Inter-American Affairs provided the initial funds. The grants given by the institute are noncompetitive and the power of recommendation rests with the chief of part and the minister of health or appropriate national authority in the country of the applicant. Grants for graduate study are divided roughly into two classes: fellowships for study with recognized institutions or scholars, generally for one year, and travel grants for observation of various phases of public health, these being of various lengths depending on the type of study desired. Under the training provided by the Inter-American Cooperative Health Services in other American republics, hundreds of persons have received instruction in sanitation, medical or nursing services and in methods of teaching the public and winning understanding and cooperation.

Pan American League Against Rheumatism.—Dr. Anibal Ruiz Moreno, Buenos Aires, Argentina, is the temporary chairman of the newly formed Pan American League Against Rheumatism, which consists of Argentina, Brazil, Canada, Chile, the United States, Mexico, Paraguay, Peru and Uruguay. Officers of the central committee appointed by the different countries are Dr. Ralph Pemberton, Philadelphia, president; Dr. Moreno, vice president; Dr. Loring T. Swain, Boston, secretary, and Dr. Fernando Herrera Ramos, Uruguay. Representatives of the American Rheumatism Association to the central committee are Lieut. Col. Philip S. Hench, M. C., and Dr. Richard H. Freyberg, New York. Representatives to the regional committee are Col. Walter Bauer, M. C., and Dr. Donald F. Hill, Tucson, Ariz.

New Corresponding Members of Internal Medicine.—The Society of Internal Medicine of the Asociación Médica Argentina, Buenos Aires, has appointed as foreign corresponding members the following physicians:

Dr. David P. Barr, New York.
Dr. Edward L. Bortz, Philadelphia.
Dr. Morris Fishbein, Chicago.
Dr. Reginald Fitz, Boston.
Dr. Louis Hamman, Baltimore.
Dr. Ernest E. Irons, Chicago.
Dr. Roger I. Lee, Boston.
Dr. William S. Middleton, Madison, Wis.
Dr. John H. Musser, New Orleans.
Dr. James E. Paulin, Atlanta, Ga.
Dr. O. A. Perry Pepper, Philadelphia.
Dr. William D. Stroud, Philadelphia.
Dr. Paul D. White, Boston.

Each of the physicians has been presented with a certificate signed by the president of the society, Dr. Egidio S. Mazzei. Dr. Mazzei has invited the new members to forward short scientific papers to be read at a meeting to be held in October in Buenos Aires, at which the general discussion will concern "Anti-Infectious Chemotherapy in Internal Medicine."

Personal.—A new factor in the technic of grafting the nerve of a cadaver to a human being is now under development by Dr. Nilson de Rezende, Rio de Janeiro, Brazil. Any peripheral nerve from a fresh cadaver, no more than twenty-four hours dead, can be removed and prepared with antiseptic solutions, washed in vitamin B complex and grafted with special technic. Dr. Rezende is reported to have said in describing his own method of utilizing a glue suture with acacia powder and pectin, according to an announcement from the Pan American World Airways.—Dr. Antonio González Ochoa, chief of the laboratory of mycology at the Institute of Public Health and Tropical Diseases, Mexico City, has gone to the United States as the guest of the U. S. Department of State.

Production of New Yeast.—The Colonial Food Yeast Limited, a corporation created by the British government to finance and manage the plant, has entrusted the West Indies Sugar Company with the construction and operation of a factory; an interest free loan of \$600,000, drawn from the Colonial and Development and Welfare Fund, will serve as capital. A. C. Thaysen of the British Department of Scientific and Industrial Research is the inventor of the yeast, which is said to contain from 40 to 50 per cent protein and all B vitamins. The anticipated cost is 12 cents per pound, and it is expected that one-half ounce will be sufficient to meet the average person's daily requirements of proteins and B vitamins. Cane sugar is the source of the yeast, and its discovery represents the result of research conducted by the British government to stimulate the sugar industry in the West Indies. One acre of agricultural land will produce only 70 pounds of protein annually, but sown in sugar cane the same area would become twelve times as productive, yielding 840 pounds of protein a year, it was stated.

Haiti Health Program Extended.—Inter-American health and sanitation work in Haiti is to be extended for another three years as the result of an agreement just concluded by the Haitian government with the Institute of Inter-American Affairs. Inter-American health work has been under way in Haiti for more than two years and has involved malarial control and installation of sanitation facilities, largely to support war activities of the island republic. Under the new agreement the work is to be continued and will be financed by a joint fund. Haiti has agreed to contribute \$150,000 to the joint fund, and the institute has agreed to contribute \$300,000. Haiti is the twelfth of the other American republics to extend inter-American health work. Under the program, eighteen of the other American republics are making a united effort to elevate health standards in the hemisphere with financial and technical aid from the United States. Dr. George C. Dunham, vice president of the Institute of Inter-American Affairs, signed the new agreement on behalf of the institute.

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 15, 1944.

Enlargement of the Council of the Royal College of Surgeons

The governing body of the Royal College of Surgeons, its council, is elected by the college fellows, a majority of whom are general surgeons. The result is that the council consists of general surgeons with only rare exceptions. The great development of specialism in modern times has rendered the practical exclusion of specialists from the council an anomaly which the present council proposes to remove. The council has sent a letter to the bodies representing ophthalmology, otolaryngology, radiology, anesthetics and general practice stating that it is felt to be increasingly important to ensure representation on the council of branches of practice which at any time may not have representation by the ordinary process of election. The council therefore will apply for such alterations in the charters as will enable it to appoint additional members for this purpose. It is intended that such appointed members may be fellows or members of the college of the same seniority as that required for those seeking election to the council, that such members shall be appointed annually after consultation with the bodies representing the different branches of practice, that the same individual shall not be eligible for reappointment beyond five years and that such appointed members shall not have the right of voting for election of the president or vice president. These proposals require alterations in the charters of the college, application for which will not be accepted till after the war. But the council considers that it should have at an early date the assistance in its deliberations of those branches not represented by any of the elected members. The present members have decided forthwith to invite representatives of these groups to attend the council meetings. The council members do not have the power to grant voting rights to those invited, but the guests will have every opportunity to express their views. The council has invited the following bodies to suggest names: the councils of British ophthalmologists, the Association of Anesthetists, the British Association of Otolaryngologists, the Faculty of Radiologists and (for general practice) the British Medical Association.

The Relief of Liberated Europe

At a conference organized by the Socialist Medical Association and the Fabian International Bureau to discuss medical relief and food supplies for needy countries after the war, some appalling facts were given of the effects of the German occupation of the countries of Europe. Dr. B. H. Sajet of the Netherlands gave recent statistics on the increase of disease there, which he said afforded some index of the conditions in other occupied countries. The incidence of diphtheria had risen from 1,273 cases in 1939 to 53,000 in 1943, he said, and over the same period the incidence of bacillary dysentery rose from 700 to 5,300 cases, and of poliomyelitis from 400 to 1,947 cases. The mortality from phthisis almost doubled between 1939 and 1942. Dr. A. Kleinzeller of Czechoslovakia reported that in one region of his country, with a population of 2 to 3 million, the incidence of typhus, which used to be 3 or 4 cases a year, was now more than 400 cases in three months. In some districts more than half the population have dysentery and more than half the infants die in their first year.

Dealing with the danger of epidemics in the liberated countries, Dr. Philip D'Arcy said that we should now be preparing teams of experts in epidemiology, not only doctors but also nurses and technical and social workers. Dr. Marc Daniels spoke of the great increase in Europe in the incidence and

mortality of tuberculosis. We must begin by improving nutrition and the standard of living, he said.

Prof. J. R. Marrack dealt with food supplies. The minimal requirement of a man was estimated at 2,000 calories daily. In Greece the average is about 1,000, in Belgium 1,400, in Europe as a whole about 1,400. Of the 400 million people in Europe, about 250 million will need help, he estimated. By 1941 milk production had fallen by a third in Denmark and meat by more than a third. If Europe is to be fed, well fed countries like Britain and the United States must eat less, it was concluded.

Sir Cuthbert Wallace: A Great War Surgeon

Sir Cuthbert Wallace, a former president of the Royal College of Surgeons, died recently in his seventy-seventh year. Among much important work, administrative as well as surgical, his services to war surgery were noteworthy. His experience in this branch was considerable, beginning with the South African war in 1899. During the first world war he was consulting surgeon to the first army of the British Expeditionary Force. His greatest achievement was the part he played in placing abdominal surgery in the classification of field surgery in war. This is well described in the *British Medical Journal* by another distinguished war surgeon, Surgeon Rear Admiral Gordon-Taylor. At the beginning of the first world war administrative authority was strongly opposed to operative intervention in gunshot wounds of the abdomen, basing this view on experience in the South African war. The evidence soon convinced Wallace that operative surgery in the forward area must be invoked if those suffering from frightful lacerations of the intestine and bleeding wounds of the mesentery were to be saved. He surreptitiously carried instruments in his pockets to forward surgical formations to implement those whose surgical activities in the abdomen was handicapped by lack of facilities. As a result of his connivance abdominal surgery in the field was born, and in the early months of 1915 the late John Campbell successfully operated on the first gunshot wound of the stomach, Owen Richards performed the first successful small intestine resection and Claude Frankau the first resection of the colon for gunshot injury.

Treatment of Carcinoma of the Prostate

A discussion took place at the Section of Urology of the Royal Society on the treatment of carcinoma of the prostate. Mr. Clifford Morson said that operations were aimed at eradicating the growth or relieving the obstruction. In attempts at radical surgery the ureters must be transplanted and the bladder and prostate removed, he stated. Having found that patients did not survive this formidable operation longer than five years, he said, he had abandoned it. But the results of inserting radium needles proved no better. He condemned castration, but later speakers did not agree with this. Mr. Kenneth Walker believed that it relieved symptoms in some patients but that endocrine treatment was better. There was general agreement as to the value of diethylstilbestrol. Mr. E. W. Riches was impressed with the dramatic results: He gave 1 mg. three times a day to begin with and worked up to 20 mg. three times a day. It was admitted, however, that the duration of the improvement still remained in doubt.

University College to Reopen

It has been decided to bring back to London, for the next university session, beginning in October, the university faculties of Arts, Science and Engineering, which have been evacuated for five years. The faculty of medicine which is attached to University College Hospital was not evacuated. Considerable damage was done to the college by German bombs. Almost the whole of the Faculty of Arts was destroyed. It will be housed in temporary quarters, which are now being prepared.

TEL-AVIV, PALESTINE

(From Our Special Correspondent)

July 6, 1944.

Smallpox

In January an infant of 4 weeks was brought to the Municipal Hospital in Tel-Aviv suffering from hernia of the umbilicus. It had a rash on the body, which developed quickly into smallpox. The entire section of the hospital was at once declared under quarantine. Three children in the same ward contracted the disease. Two of them died, and the third suffered an acute form of smallpox. By means of strict quarantine, and thanks to the fact that in this country children are vaccinated against smallpox at an early age, the epidemic was localized and no further cases occurred. The origin of the first case was investigated, and it was found that the father of the infant was employed outside Tel-Aviv in a locality where there were some cases of smallpox; evidently he had transferred the disease to the infant without contracting it himself.

Recently a slight epidemic of smallpox broke out in Haifa, where 20 cases have occurred. The medical authorities are in control of the situation.

On April 1 several cases of smallpox were discovered in the southern parts of the country, and by the end of the month these had reached the proportions of a light epidemic. There were 40 cases, all among the Arab fellahin and Bedouins. Strangely enough, the number of children who contracted the disease was small; most of the patients were adults, including some elderly men. This is explained by the fact that the adults had not been vaccinated in childhood, or if they had been vaccinated the immunity had expired. There have been only 4 fatal cases. The department of health of the government of Palestine and the health institutions of the Jewish community have taken steps to localize the epidemic and to vaccinate large numbers of the population.

Leishmaniasis of the Skin

The main home of leishmaniasis in Palestine is considered the ancient city of Jericho and its surroundings north of the Dead Sea. In the Jewish settlement south of the Dead Sea this disease is unknown. In 1926 Dr. Dostrowsky discovered a few nests in some quarters of Jerusalem. Dr. Sternfeld has now published a summary of 189 cases which he encountered in the North of Palestine in 1938-1943. Published in *Harefuah*, the journal of the Palestine Jewish Medical Association, his conclusions are as follows:

1. Leishmaniasis, an endemic disease in Palestine, is continually spreading. Haifa and the northern part of Palestine, which were heretofore considered free from Leishmaniasis, have also become nests of this disease during recent years.

2. The spreading of the disease from its original foci in the neighborhood of the Dead Sea and Jericho is apparently connected with the industrial development of this district. Immigration from affected regions like Aleppo, and the habit of the Arabs of leaving it untreated, are additional contributory factors to the spread of the disease.

3. New centers of leishmaniasis are bound to appear in the North if the sporadic cases are not discovered early and radically treated.

Activities of Kupat Holim in Infant Welfare Stations and Schools

In 1943, 31 infant welfare stations were maintained by Kupat Holim, the sick fund of the general federation of Jewish labor in Palestine. In addition, ninety agricultural settlements were visited by a children's doctor, and fifty schools were under medical supervision.

Kupat Holim, through its infant welfare stations, serves a third of the Jewish infants of the country. Of the 10,000 infants born to Jewish parents, Kupat Holim takes care of 30 per cent,

Hadassah 40 per cent and the municipality of Tel-Aviv 28 per cent. Infant mortality of the infants treated in the infant welfare stations declined from 3 per cent in 1936 to 1 per cent in 1942.

Nearly 7,500 children in fifty schools are under the supervision of Kupat Holim. The first aim of medical supervision over schools is prevention of the spread of infectious diseases. During 1941, convalescent camps were arranged for 572 children, 547 children received dental treatment, 328 children received orthopedic treatment and 131 children were fitted with glasses. Trachoma has become almost nonexistent. Pediculosis has dropped from 13-19 per cent to 3 per cent.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Aug. 12, page 1059.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Various centers, Nov. 13-15. Part III. Various centers, September or October. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Part I. Various centers, Jan. 19. Final date for filing application is Oct. 21. Sec., Dr. P. M. Wood, 745 Fifth Ave., New York 22.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I. Various centers, February. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Oct. 5-7. Los Angeles, January. Final date for filing application is Oct. 1. New York, June. Chicago, October. Final date for filing application is Dec. 1. Sec. Dr. S. Judd Beach, 56 Ivie Road, Cape Cottage, Maine.

AMERICAN BOARD OF OTOLARYNGOLOGY: Oral. Chicago, Oct. 4-7. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Oral*. New York, April 14-15. Final date for filing application is Dec. 15. Chicago, May 19-20. Final date for filing application is Jan. 19. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY: *Oral*. New York, December. Final date for filing application is Sept. 30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N.W., Washington 6, D. C.

Society Proceedings

COMING MEETINGS

Aero Medical Association of the United States, St. Louis, Sept. 4-6. Dr. David S. Brachman, 5440 Cass Ave., Detroit 2, Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Oct. 8-12. Dr. W. L. Benedict, 102 Second Ave. S.W., Rochester, Minn., Secretary.

American Association of Obstetricians, Gynecologists and Abdominal Surgeons, Hot Springs, Va., Sept. 7-9. Dr. James R. Bloss, 418 Eleventh St., Huntington, W. Va., Secretary.

American Congress of Physical Therapy, Cleveland, Sept. 6-9. Dr. Richard Kovacs, 2 East 88th St., New York 28, Secretary.

American Hospital Association, Cleveland, Oct. 2-6. Mr. George P. Bugbee, 18 East Division St., Chicago, Executive Secretary.

American Pediatric Society, Atlantic City, N. J., Sept. 25-27. Dr. Hugh McCulloch, 325 N. Euclid Ave., St. Louis 8, Secretary.

American Public Health Association, New York, Oct. 3-5. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Roentgen Ray Society, Chicago, Sept. 24-29. Dr. H. Dabney Kerr, University Hospitals, Iowa City, Secretary.

Colorado State Medical Society, Denver, Sept. 27-29. Dr. John S. Bouslog, 537 Republic Bldg., Denver 2, Secretary.

Delaware Medical Society of the, Lewes, Sept. 11-12. Dr. W. O. La Motte, 601 Delaware Avenue, Wilmington, Secretary.

District of Columbia Medical Society of the, Washington, Oct. 5-7. Mr. Theodore Wiprud, 1718 M St. N.W., Washington, Secretary.

Indiana State Medical Association, Indianapolis, Oct. 3-5. Mr. T. A. Hendricks, 23 East Ohio St., Indianapolis 4, Executive Secretary.

International College of Surgeons, U. S. Chapter, Philadelphia, Oct. 3-5. Dr. Desiderio Roman, 250 South 17th St., Philadelphia, Secretary.

Kentucky State Medical Association, Lexington, September 18-20. Dr. P. E. Blackerby, 620 S. Third St., Louisville, Secretary.

Michigan State Medical Society, Grand Rapids, Sept. 27-29. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Secretary.

Mississippi Valley Medical Society, Peoria, Ill., Sept. 27-28. Dr. Harold Swanberg, 510 Maine St., Quincy, Ill., Secretary.

Northern Minnesota Medical Association, Hibbing, Aug. 26. Dr. R. N. Jones, 8 3/4th Ave. N., St. Cloud, Secretary.

Oregon State Medical Society, Portland, Sept. 2-3. Dr. Thomas D. Robertson, St. Vincent's Hospital, Portland, Secretary.

Pennsylvania Medical Society of the, State of, Pittsburgh, Sept. 19-21. Dr. Walter F. Donaldson, 800 Penn. Ave., Pittsburgh 22, Secretary.

Radiological Society of North America, Chicago, Sept. 24-29. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse, N. Y., Secretary.

Utah State Medical Association, Salt Lake City, August 21-26. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.

Wisconsin State Medical Society of, Milwaukee, Sept. 18-20. Mr. Charles H. Crownhart, 110 E. Main St., Madison 3, Secretary.

Deaths

Andrew Porter Biddle Ⓢ Detroit; Detroit College of Medicine, 1886; an Affiliate Fellow of the American Medical Association; since 1917 emeritus professor of dermatology and syphilology at his alma mater, now known as the Wayne University College of Medicine; formerly professor of dermatology at the Detroit Post-Graduate School of Medicine; in addition to serving as secretary and counselor to the Michigan State Medical Society, he had been president for two successive terms from 1916 to 1918; formerly secretary of the Wayne County Medical Society; a member and past president of the Detroit Academy of Medicine; first president of the Detroit Dermatological Society in 1922; member of the Chicago Dermatological Society; member of the American Dermatological Association, serving as president in 1925-1926; fellow of the American College of Physicians; specialist certified by the American Board of Dermatology and Syphilology; for six years a member of the state board of health; a member of the board of education of Detroit from 1917 to 1925, when he became president; a member of the Detroit Library Commission for many years and president in 1931; served for a long period in the Michigan National Guard and had been commissioned major and surgeon of the 31st regiment during the Spanish-American War; in 1892 appointed U. S. Pension Examining Surgeon; consultant on the staffs of Receiving Hospital, St. Mary's, Woman's Hospital, Children's Hospital, St. Joseph's Mercy Hospital, the Protestant Children's Home of Detroit and the Detroit Board of Health; in recognition of his loyal and continuous service, the state medical society created the annual Andrew P. Biddle Oration; in 1929 received the honorary degree of doctor of science from the College of the City of Detroit and in 1935 the honorary degree of master of arts from the University of Michigan, Ann Arbor, "in recognition of a life devoted to the advancement of education and ethics in the medical profession"; member of the Naval and Military Order of the Spanish-American War and a Companion of the Military Order of Foreign Wars; first editor of the *Journal of the Michigan State Medical Society*, serving from 1902 to 1906; died August 2, aged 82.

Rudolph Jerome Price, Dayton, Ohio; University of Michigan Medical School, Ann Arbor, 1923; member of the Ohio State Medical Association, American Roentgen Ray Society, Radiological Society of North America, Inc., and the American College of Radiology; specialist certified by the American Board of Radiology; intern at the Miami Valley Hospital, 1923-1924; awarded the French Croix de Guerre for services during World War I; recently appointed by the army as a consultant at Wright Field; radiologist at the Good Samaritan Hospital; secretary of the Dayton Hospital board; died June 8, aged 48, of injuries received in an automobile accident.

Winfred Wilson Ⓢ Memphis, Texas; Johns Hopkins University School of Medicine, Baltimore, 1904; member and past president of the Panhandle District Medical Society; at one time professor of pathology at the Baylor University College of Medicine, Dallas; for many years health officer of the city of Memphis and of Hall County; operated the Memphis Hospital; since 1917 local surgeon for the Fort Worth and Denver Railroad; during World War I, chairman and physician for the Selective Service Board number 1 in Hall County, and chairman of the Hall chapter of the American Red Cross; died in the Union Memorial Hospital, Baltimore, May 1, aged 64, of coronary occlusion and peritonitis following intestinal obstruction.

Charles William Farr Ⓢ Major, U. S. Army, retired, Buffalo; University of Vermont College of Medicine, Burlington, 1897; veteran of the Spanish-American War; entered the U. S. Army as an assistant surgeon in 1901; became a captain in 1906; retired as a major in 1910 because of disability in line of duty; returned to active duty intermittently until Aug. 15, 1932, when he was again retired; formerly professor of military science and tactics at the University of Buffalo School of Medicine; at one time physician at the Sing Sing Prison; died in the Edward J. Meyer Memorial Hospital July 11, aged 68, of cerebral thrombosis.

Frank Henry Hacking, Minneapolis; Rush Medical College, Chicago, 1899; member of the Minnesota State Medical Association; one of the founders of the Minnesota Association for Crippled Children; a director of the Hennepin County Tuberculosis Association; attending specialist in charge of the tuberculosis department of the U. S. Veterans Bureau from

1919 to 1926; served as physician in charge of the Hopewell and Thomas tuberculosis hospitals, on the staff of the Glen Lake Sanatorium, Oak Terrace, and the Fairview Hospital, where he died June 2, aged 72, of coronary occlusion and cerebral thrombosis.

Charles Edward Caine Ⓢ Morris, Minn.; University of Minnesota College of Medicine and Surgery, 1896; served for many years as a member of the state board of medical examiners, of which he had been past president; since January 1942 mayor of Morris; for six years member of the city commission; served as city and county physician, as county coroner for many years and as member and president of the local board of education; medical director and owner of the Morris Hospital; surgeon in Morris for the Great Northern and Northern Pacific railways; died April 15, aged 75, of coronary occlusion.

Burton Whitford Christie Ⓢ Omaha; Omaha Medical College, 1902; past president of the Omaha-Douglas County Medical Society; served as assistant professor of medicine and pediatrics at the University of Nebraska College of Medicine; for many years on the staff of the Immanuel Hospital; surgeon for the Burlington Railroad; died in a Portland, Ore., hospital May 27, aged 66, of heart disease following pulmonary edema.

William Harvey Cooke Ⓢ East Orange, N. J.; Boston University School of Medicine, 1888; a founder of the Homeopathic Hospital of Essex County, now known as the East Orange General Hospital, of which he had been a member of the board of directors and where he died June 6, aged 77, of cerebral hemorrhage.

William Seward Dart, Oneonta, N. Y.; Eclectic Medical College of the City of New York, 1890; member of the Medical Society of the State of New York; member of the associate staff of the Aurclia Osborn Fox Memorial Hospital, where he died June 13, aged 78, of uremia.

George Pitzer Dougherty, Farina, Ill.; Barnes Medical College, St. Louis, 1911; died June 5, aged 56, of coronary thrombosis.

Francis G. Earley Ⓢ Ridgway, Pa.; Jefferson Medical College of Philadelphia, 1885; on the staff of the Andrew Kaul Memorial Hospital, St. Marys; died May 7, aged 80, of carcinoma of the left lung.

Edwin M. Stanton Edwards Ⓢ Trinway, Ohio; Baltimore Medical College, 1898; died in the City Hospital, Coshocton, June 11, aged 71, of pneumonia.

Herman Frederick Fraser, Detroit; Detroit College of Medicine and Surgery, 1927; member of the Michigan State Medical Society; interned at the Henry Ford Hospital; member of the staff of Northwestern Branch of Grace Hospital; died in the Woman's Hospital June 5, aged 56, of coronary occlusion.

Cornelius J. Geenen Ⓢ Grand Rapids, Mich.; State University of Iowa College of Medicine, Iowa City, 1926; senior surgeon, Butterworth Hospital, where he died June 7, aged 47, of agranulocytosis.

Abraham Chester Green, Chicago; Northwestern University Medical School, Chicago, 1910; member of the city health department; died in the Wesley Memorial Hospital June 7, aged 57, of bronchopneumonia, chronic myocarditis and chronic glomerular nephritis.

Franklin Jacob Hahn Ⓢ Bath, Pa.; Jefferson Medical College of Philadelphia, 1895; served for many terms on the school board; director and vice president of the First National Bank; died June 4, aged 73, of heart disease.

Jabez Masten Harman, Floyd, Va.; University of Louisville (Ky.) Medical Department, 1891; member of the Medical Society of Virginia; coroner and chairman of the Floyd County Board of Health; died June 3, aged 77, of injuries received in an automobile accident.

Elizabeth Mercelis, Montclair, N. J.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1892; served on the staffs of the Mountinside and St. Vincent's hospitals; formerly member of the board of health and school physician; died June 1, aged 75, of coronary occlusion.

James Leland Merrell, Hoxie, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1924; also a pharmacist and lawyer; member of the Arkansas Medical Society; president of the Lawrence County Medical Society; served in the medical corps of the U. S. Army during World War I; member of the board of education; on the staff of the Missouri Pacific Hospital, Little Rock; surgeon of the Missouri Pacific Rail-

road Company; died in Little Rock June 12, aged 55, of carcinoma of the lung.

Hugo Neukamp, Hosmer, S. D.; Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, Germany, 1898; member of the South Dakota State Medical Association; killed in an automobile accident June 1, aged 68.

Edwin Plassnig, Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1925; member of the Medical and Chirurgical Faculty of Maryland; served during World War I; physician for the Baltimore Transit Company; on the staffs of the Mercy Hospital and the South Baltimore General Hospital, where he died June 6, aged 47, of chronic glomerulonephritis.

Harry Allen Richter Ⓢ Kenilworth, Ill.; Northwestern University Medical School, Chicago, 1923; member of the American Heart Association and the American Therapeutic Society; fellow of the American College of Physicians; intern at the Kings County Hospital in Brooklyn, 1923-1924; member of the staff of the Swedish Covenant Hospital, Chicago, and cardiologist at St. Francis Hospital, Evanston, where he died July 8, aged 47, of carcinoma of the bladder and rectum.

Daniel Rutgers Robert Ⓢ New Lebanon Center, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1911; served during World War I; served as health officer of Canaan and New Lebanon Center; attending physician at the Berkshire Industrial Farm, Canaan, where he died June 21, aged 59, of coronary thrombosis.

Robert Rosenberg, Brooklyn; Fordham University School of Medicine, New York, 1917; died in the Flower and Fifth Avenue Hospitals June 13, aged 55, of tumor of the brain.

Harry Preston Sayle, Tillatoba, Miss.; University of Louisville (Ky.) Medical Department, 1912; died May 10, aged 57, of acute dilatation of the heart.

Peter Arthur Scheurer Ⓢ Manchester, Mich.; Detroit College of Medicine, 1908; member of the school board and the village council; president of the People's Bank; for many years a member of the staff of the Mercy Hospital, Jackson, where he died June 9, aged 59, of myocardial failure.

Elisha Lewis Sencindiver, Martinsburg, W. Va.; University of Maryland School of Medicine, Baltimore, 1891; one of the founders of the King's Daughters' Hospital; died June 19, aged 77, of coronary thrombosis.

William Ward Seward, Surry, Va.; Medical College of Virginia, Richmond, 1897; member of the Medical Society of Virginia; past president of the Post-Graduate Medical Society of Southside Virginia; chairman of the medical advisory board for Surry and Sussex counties during World War I; died May 5, aged 70, of pyelonephritis.

Marshall J. Shaw, Plainview, Texas; University of Tennessee Medical Department, Nashville, 1892; died April 30, aged 91, of cerebral hemorrhage.

Charles Almon Sheely, Gulfport, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1898; member of the Mississippi State Medical Association; formerly associated with the U. S. Public Health Service; served as district surgeon for the Louisville and Nashville and the Illinois Central railroads; died in the King's Daughters' Hospital May 19, aged 75, of cerebral hemorrhage.

Dustin Samuel Shiepe, Springfield, Mass.; Tufts College Medical School, Boston, 1943; intern at the Mercy hospital, where he died May 26, aged 26, of coronary thrombosis.

James Young Simpson Ⓢ Evanston, Ill.; College of Physicians and Surgeons, New York, 1882; an Affiliate Fellow

of the American Medical Association; member of the Missouri State Medical Association; died May 2, aged 83, of cerebral thrombosis.

John Siveke Ⓢ Passaic, N. J.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1913; chief medical inspector for the public schools in Passaic; on the staff of the Passaic General Hospital; died May 9, aged 59, of cerebral hemorrhage, hypertension and arteriosclerosis.

Alexander Soble, Elmira, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1922; member of the Medical Society of the State of New York; on the staff of St. Joseph's Hospital; died June 11, aged 46, of accidental barbitol poisoning.

Edward Isaac Stanley Ⓢ Albany, Ohio; Starling Medical College, Columbus, 1898; died May 9, aged 69, of coronary thrombosis.

Ichabod Thomas Sutton, Prattville, N. Y.; Albany (N. Y.) Medical College, 1890; member of the Medical Society of the State of New York; served as county coroner and as health officer of Prattville and Ashland; died May 12, aged 81, of diabetes mellitus and general arteriosclerosis.

Otto William Thie Ⓢ St. Louis; St. Louis University School of Medicine, 1912; visiting physician on the staff of the Missouri Pacific Hospital; died May 31, aged 69, of heart disease.

Oscar Theodore Thomas, Cleveland; University of Pennsylvania Department of Medicine, Philadelphia, 1892; formerly assistant clinical professor of gynecology at the Western Reserve University School of Medicine; a member of the staff of the Woman's Hospital and formerly on the staffs of the Charity Hospital and the City Hospital, where he died June 3, aged 74.

David Chester Thompson Ⓢ Assistant Surgeon, Lieutenant, U. S. Navy, retired, Jacksonville, Fla.; Manitoba Medical College, Winnipeg, Man., Canada, 1905; retired from the Navy

Dec. 16, 1921; medical officer for the U. S. Sugar Corporation, Azucar; died in Pahokee June 5, aged 63, of diabetes mellitus.

Francis Meredith Vessells, Perryville, Mo.; Missouri Medical College, St. Louis, 1899; served as a major in the medical corps of the U. S. Army during World War I; died May 23, aged 69, of cardiorenal disease.

KILLED IN ACTION

William Ireys Hunt, Greenville, Miss.; Tulane University of Louisiana School of Medicine, New Orleans, 1942; served an internship at the Charity Hospital, New Orleans; began active duty in the medical corps, Army of the United States, as a first lieutenant on June 30, 1943; later promoted to captain; cited for heroism in crawling under fire to relieve the sufferings of wounded Americans and Japanese; killed in action on Bougainville June 5, aged 30.

George Emmanuel Mortis, Peabody, Mass.; Middlesex College of Medicine and Surgery, Waltham, 1932; served as city physician; commissioned a first lieutenant in the medical corps, Army of the United States, on July 11, 1942; later promoted to captain; awarded the Purple Heart; died on the isle of Capri January 1, of wounds received in action, aged 38.

CAPT. WILLIAM I. HUNT
M. C., A. U. S., 1913-1944

CAPT. GEORGE E. MORTIS
M. C., A. U. S., 1905-1944

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

- *Effect of Intravenously Administered Digoxin and Ouabain on Systemic Venous Pressure of Patients with Congestive Heart Failure. L. W. Eichna and H. Taube.—p. 641.
- Further Observations on Ischemia Injury Pattern Produced in Dog by Temporary Occlusion of Coronary Artery. Incomplete T Diversion Patterns, Theophylline T Reversion and Theophylline Conversion of Negative T Pattern. R. H. Bayley, J. S. La Due and Dorothy Joseph York.—p. 657.
- Persistent Displacement of RS T Segment in Case of Metastatic Tumor of Heart. F. F. Rosenbaum, F. D. Johnston and V. V. Alzamora.—p. 667.
- Heart Block: Influence of Ventricular Systole on Auricular Rhythm in Complete and Incomplete Heart Block. A. E. Parsonnet and R. Miller.—p. 676.
- Congenital Cardiac Disease Bibliography of 1,000 Cases Analyzed in Maude Abbott's Atlas, with an Index D. deF. Bauer and E. C. Astbury.—p. 688.

Intravenous Digoxin and Ouabain in Congestive Heart Failure.—While studying the circulatory effects of purified cardiac glycosides a rapid fall of the elevated venous pressure was encountered when these drugs were administered intravenously to patients with congestive heart failure. The subjects of the study by Eichna and Taube were hospitalized patients with organic heart disease of widely varying kinds. All had congestive heart failure. Venous pressure was measured in the antecubital veins by the direct method, using a manometer filled with isotonic solution of sodium chloride. The ventricular rate was counted, always for one full minute, by auscultation over the precordium. Arterial blood pressure was measured by the usual auscultatory method, employing a mercury manometer. Electrocardiograms were obtained by the standard limb leads. To ascertain the rate of the flow of urine, a catheter was placed in the urinary bladder and allowed to drain continuously. At ten minute intervals the amount of urine collected was measured, removed and recorded. These measurements were made frequently and often simultaneously, throughout an adequate control period and for two to four hours after injection of the glycoside. Thereafter, they were made daily or less frequently. The authors found the administration of single therapeutic doses of "Digoxin" and ouabain induced rapid improvement in the circulatory dynamics of patients with congestive heart failure. A rapid fall of the elevated venous pressure was the most striking and constant effect. It had the following characteristics: Onset of effect: ouabain three to eleven minutes, digoxin five to twenty-two minutes. Major effect: ouabain thirty-five to fifty-six minutes, digoxin forty-five minutes to three hours. It was associated with, but not dependent on, slowing of the ventricular rate when the cardiac mechanism was auricular fibrillation. It was unaccompanied by a change in ventricular rate when the cardiac mechanism was normal. It preceded the onset of diuresis, which at times was rapidly initiated. Its pattern did not depend on the initial level of venous pressure or the degree of congestive heart failure. It bore no relationship to changes in the electrocardiogram. Its duration was relatively short except in those patients whose cardiac reserve was sufficient to maintain circulatory compensation once it was reestablished. Compared molecule for mole-

cule, ouabain induced effects more rapidly than digoxin. Large doses of these two glycosides at times induced toxic complications. The intermediate doses were free of these effects and therapeutically just as effective.

Anesthesiology, New York

5:225-328 (May) 1944

- *Production of Negative Pressure in Respiratory Tract by Ciliary Action and Its Relation to Postoperative Atelectasis. A. C. Hilding.—p. 225.
- Survival of Preserved Red Cells After Transfusion. O. F. Denstedt, Dorothy E. Osborne, H. Stansfield and I. Rochlin.—p. 237.

- Diffusion Respiration in Dog Anesthetized by Pentothal Sodium. W. B. Draper and R. W. Whitehead.—p. 262.
- Analysis of Inhalation Anesthesia by Graphic Means. P. Saunders.—p. 274.
- Studies on Paraldehyde: II. Median Lethal Dose, LD₅₀, of Paraldehyde for Both Young and Old Rats on Two Dietary Regimens. G. W. Phillips, E. B. Carmichael and F. A. Kay.—p. 287.
- Anesthesia: X. Irritative Action of Volatile Anesthetics on Mucous Membranes and Relationship Between Potency and Chemical Constitution. J. C. Krantz Jr., C. J. Carr and W. E. Evans Jr.—p. 291.

Ciliary Action in Respiratory Tract and Postoperative Atelectasis.—Hilding describes experiments which demonstrated that ciliary power acting on masses of occluding mucus can produce negative pressure in both the upper and lower parts of the respiratory tract. Steps in the production of postoperative pulmonary atelectasis seem to be about as follows: (1) production of an excessive amount of secretion; (2) formation of occluding masses in the air passages partly because of reduced respiration through splitting of diaphragm and pain and because the patient lies quietly in one position; (3) movement of a succession of these masses upward in the tract by ciliary action; (4) removal of a quantity of air by each of these masses; (5) progressive shrinkage of the affected lobes as air is removed; (6) compensatory distention of neighboring lobes; (7) production of considerable negative pressure within an affected lobe when the contained air has been exhausted; (8) immobilization of the mucus in the bronchus by atmospheric pressure.

Surgical Treatment of Hyperinsulinism.—Bell and his associates report 3 cases in which operation was performed for hypoglycemia resulting from hyperinsulinism. Symptoms suggesting hypoglycemia were present in all 3 and the minimum fasting blood sugar determinations were considerably below 50 mg. per hundred cubic centimeters. Solitary tumors of the pancreatic islet cells were excised from the region of the tail of the pancreas in 2 of the patients. In 1 of these the tumor was almost completely extrapancreatic. Its gross appearance was similar to that of an accessory spleen or hemolymph node.

and although it was adjacent to the inferior aspect of the pancreas its attachment to this organ was apparent only on microscopic examination of the specimen. The third patient was known to have had diabetes mellitus for seven years. Episodes of hypoglycemia appeared and became progressively more frequent and severe over a period of a few weeks. At operation no evidence of tumor or aberrant pancreatic tissue could be found. A partial resection of the pancreas was performed. The condition of diabetes mellitus recurred following the operation, and subsequently the patient has remained diabetic. Pathologic examination of the part of the pancreas excised showed alterations in the staining of the tissue, suggesting the presence of islets of Langerhans that were increased in number and size. Hyperinsulinism may be caused by tumors containing actively secreting islet cells or by the hypersecretion of insulin in a pancreas in which the islets of Langerhans may appear to be either normal or increased in size and number. Aberrant pancreatic tissue also is a possible source. Rarely, hyperinsulinism has appeared in patients who previously had diabetes mellitus. The clinical manifestations of hyperinsulinism do not appear in all patients with tumors of the islet cells. Such tumors may be found at necropsy or during laparotomy for other abdominal conditions. It is supposed that insulin is elaborated by the beta cells of the islets of Langerhans and that tumors of the islet cells giving clinical manifestations of hyperinsulinism contain appreciable numbers of these cells. The dietary management of patients with hypoglycemia consists of low carbohydrate, high protein, high fat food given at frequent intervals (six meals a day).

Swelling of Arm Following Radical Mastectomy.—Having seen a patient who developed swelling of the arm two and one-half years after radical mastectomy, Holman and his associates tried to determine the cause of such swelling. They examined 100 patients who had been subjected to radical mastectomy between six months and eleven years previously. They were not consecutive cases but were selected because they were available for follow-up examination. The arms of these patients were measured, the presence or absence of swelling noted and data collected relating the swelling to grafting, infection, recurrence and roentgenotherapy. The authors found that primary skin grafting has no influence on the occurrence of swelling of the arm following radical mastectomy. Swelling of the arm cannot be assumed to signify recurrence of carcinoma. The presence or absence of metastases to the axillary nodes at the time of operation has no bearing on the swelling. In this series of cases by far the greatest factors in the cause of swelling of the arm were infection and x-ray dermatitis.

Ulcerative Colitis: Clinical Experiments with Pig's Intestine. A. M. Gill.—p. 536.

Kala Azar Treated with 4:4' Diamidinostilbene.—Somers says that until the introduction of 4:4' diamidinostilbene in 1939 treatment of kala-azar in the Anglo-Egyptian Sudan had been most disheartening. The drugs in general use at the time were antimony tartrate, "neostibosan" and urea stibamine. During the last eight years the author has treated 26 patients with kala-azar in the Sudan; the first 21 were treated with either antimony tartrate or neostibosan. They died in the hospital or ran away before completing their treatment; none showed permanent improvement. The last 5 patients were treated with the urea derivative 4:4' diamidinostilbene and responded favorably; 4 of them were alive and well when seen between eight and nine months after their apparent cure; only four months had elapsed since the fifth patient completed treatment when he was last seen. The drug was given at intervals of one to three days in doses gradually increased from 1 mg. to 4 mg. per kilogram of body weight. The total amount varied from 3.01 Gm. to 4.88 Gm.

Malaria as a Nonrelapsing Disease.—Rodger presents a survey which he undertook to test his belief that malaria is an easily curable disease and that its reputation for relapsing is often the result of reinfection. He made his observation in a copper mine of northern Rhodesia on a European population of 2,500, which, though living in a hyperendemic area where the parasite and spleen indexes are between 50 and 60 per cent in native children, is yet so well protected by antilarval and anti-mosquito measures that the average expectation of an attack is once in every seven or eight years. European employees, over 1,000 in number, are not permitted a day's stay off work without a medical certificate, nor can they return to work without a further certificate. No quinine is issued to employees except in the course of treatment. Blood smears are taken from every febrile patient, and no patient is treated for malaria until parasites are found in the blood. Every patient is treated in a hospital, and no one is allowed to rely on the casual and haphazard administration of quinine or atabrine. The present series covers five years. There were in all 1,619 cases of malaria in Europeans. These represented attacks in 1,157 persons, 842 of whom had only one attack. Thus 72.7 per cent of infected persons did not suffer a second attack in five years. Of the remaining 27.3 per cent a large proportion are probable reinfections and not relapses. Atabrine is given when there is a history of blackwater fever, quinine idiosyncrasy or previous irregular quinine administration over long periods. Plasmodium ovale infections require a course of quinoplasmoquine and some quartan cases also require some such combination.

Local Analgesia in Periarticular Fibrositis of Knee.—Kelly maintains that pain in the region of the knee joint, when not due to mechanical derangements or to well defined disease such as tuberculosis or rheumatoid arthritis, will frequently be found associated with fibrositic lesions of adjacent muscles. Periarticular fibrositis can be differentiated from arthritis

because of the absence of redness, widespread tenderness and muscular atrophy, and there is little evidence of fluid in the joint. There is a well defined area of tenderness in muscle, and referred tenderness may be found over a greater or lesser area of the joint surface. The pain may or may not be accompanied by swelling; the range of movement usually is limited, though the degree varies. The pain may be worse on weight bearing, or the patient may complain bitterly of aching at night. The lesion may follow an injury, or it may appear spontaneously. The pain is felt more commonly on the inner side of the joint, and tenderness will be detected more frequently on the medial side. Injection of a local anesthetic into the joint capsule may counteract pain and restore mobility, but the relief is not lasting. Adjacent muscles should be searched for tender spots, and when these are anesthetized the tenderness of the capsule disappears and the relief is often permanent. In the great majority of instances the author has found muscular lesions on the inner side posteriorly. A number have been found in the inner fibers of the calf muscles behind the tibial condyle; but by far the commonest site is in relation to the inner condyle of the femur, at what the author terms the "adductor tubercle spot." Points of tenderness may be found along the upper border of the condyle, or a lesion may be found a little farther back in the fibers of the semimembranosus muscle. On deep infiltration of the lesions the tenderness of the whole internal aspect of the knee will disappear, together with other symptoms, such as pain on weight bearing and limitation of flexion. In many cases articular or periarticular swelling accompanied the other signs; if the treatment was successful in allaying the pain, the swelling subsided in the course of a few days. Manifestations of arthritis in some cases are brought about by a nervous reflex.

*Action of Chlorophyll on Healing of Wounds. Marie Louise Boehringer.—p. 793.

Action of Chlorophyll on Healing of Wounds.—Boehringer compared the healing effect of chlorophyll ointments of different concentrations with other ointments and an ointment base. Her experiments were made on rabbits. She found that chlorophyll ointment promotes the healing of wounds. The wounds dried more quickly, the granulations were stronger and healthier, epithelization was more rapid and the wounds shrank in size much better than when the other ointments were used. Whereas the control wounds nearly always showed inflammatory changes and were extremely sensitive to pressure, this occurred only exceptionally in the wounds treated with chlorophyll. The scars resulting after treatment with chlorophyll were easily movable on the base, whereas in the wounds treated with the other ointments adhesions with the underlying fascia were frequent. The ideal concentration of the chlorophyll ointment has not been ascertained. Concentrations of 0.01 and of 0.5 per cent effect a noticeable acceleration in wound healing.

Schweizerische medizinische Wochenschrift, Basel

73:841-864 (July 3) 1943. Partial Index

Inauguration of New Teaching Method by the Faculty of Medicine at the University in Geneva. R. de Seigneux.—p. 855.

Involvement of the Inner Ear in Epidemic Parotitis.—Rodel advocates functional tests of hearing for all cases of bilateral swelling of the parotid and particularly for those of

uncertain origin. The importance of this was well demonstrated in the case of a woman aged 48 who had had measles, scarlet fever, diphtheria, whooping cough and dysentery, but not mumps. A septicopyemic condition spreading from the parotid and a posterior pharyngeal abscess were the predominant features on her admission at the laryngologic clinic. Diagnosis of unilateral epidemic parotitis with mixed infection and secondary perforation of the parotid abscess into the external acoustic canal and into the posterior pharyngeal cavity was made. A sudden onset of neuralgic pain in the area of the facial nerve and of all three branches of the fifth nerve within twenty-four hours prior to the swelling of the parotid was considered as a premonitory sign of toxic-infective lesions of those cerebral nerves. The septicopyemic condition subsided after the removal of the posterior pharyngeal abscess by tonsillectomy, whereas the external incision of the parotid abscess had failed to control the infection. The involvement of the inner ear, demonstrated by the functional hearing tests, represented a meningeal complication of epidemic parotitis. Loss of hearing on the right side continued for some time. Paresis of the facial nerve occurred on the sixteenth day of the disease and continued for weeks without improvement. The destructive character of the suppurative inflammation of the parotid was considered responsible. Increase in the pressure of the cerebrospinal fluid (500 mm.) suggested primary irritation of the meninges. The functional hearing tests and the lumbar puncture clarified the diagnosis.

Bol. del Instituto de Maternidad, Buenos Aires

12:1-346 (Dec.) 1943. Partial Index

- *Sulfonamide Therapy in Prevention of Infection in Cesarean Section in Contaminated Cases. A. Peralta Ramos.—p. 21.
*Obstetric Shock. R. Caso and J. J. Báez.—p. 160.
Endometriosis. A. Peralta Ramos and H. Mónaco.—p. 296.

Sulfonamide Therapy in Cesarean Section.—Peralta Ramos reports the results of cesarean sections on two groups of parturients, 429 and 69 patients respectively. The patients in both groups belonged to three grades of contamination, second, third and fourth degrees. Sulfanilamide or sulfapyridine powder 4 or 5 Gm. was applied to the peritoneum in the second group of patients. Mortality amounted to 3.49 per cent in the group not given sulfonamide and to 1.45 per cent in the treated group. The only patient who died in the sulfonamide group was a patient classified as representing the third degree of contamination. The patient died from generalized peritonitis. The effect of local application of the drug after cesarean section in infected cases is less favorable than that in other surgical interventions. The less favorable effect is due to the functional lability of the hepatic and renal systems in pregnancy and to the difficulties in identifying the causal bacteria of the infection. Local application of sulfanilamide, reinforced in certain cases by oral administration of the drug, is of value after cesarean section in contaminated cases. Hysterectomy is indicated only in very grave cases of acute uterine infection.

Obstetric Shock.—Caso and Báez report 5 cases of obstetric shock. They believe that obstetric shock is vasogenic. The most frequent form is that which follows acute hemorrhage. Adrenal dysfunction and imbalance of the sympathetic nervous system are the main causal factors. Preventive therapy consists in proper antepartum care and of administration of adrenal cortex extract if there are symptoms of adrenal insufficiency. The therapy of shock is one of emergency. It consists in plasma or blood transfusion and the treatment of the associated gynecologic and general disorders. Plasma is indicated in post-hemorrhagic shock, provided the amount of hemoglobin is not greatly diminished. Blood of the O group is used in blood transfusion when the latter follows administration of plasma. Heart tonics are interdicted. Vasoconstrictive drugs are unnecessary after plasma or blood transfusion because of the spontaneous peripheral vasoconstriction which follows either plasma or blood transfusion. Morphine is contraindicated if there is cyanosis.

Book Notices

Minor Surgery. By Frederick Christopher, S.B., M.D., F.A.C.S., Associate Professor of Surgery at Northwestern University Medical School, Chicago. Fifth edition. Cloth. Price, \$10. Pp. 1,006, with 575 illustrations. Philadelphia & London: W. B. Saunders Company, 1944.

This is a splendid book on minor surgery containing an enormous amount of information. It has an extensive bibliography, which is well chosen and up to date. The author quotes freely from medical literature but now and then presents perhaps too many ideas on a given point. The discussion on varicose veins might be considered an example of too many views without specific recommendations of any one as being preferable. In general, the reviewer agrees entirely with the author in presenting more than one view when the subject is controversial and sound arguments and good minds are on both sides. Most of the illustrations are borrowed but well chosen. Even the best books have a few weak spots. On page 4 the author has included a brief discussion on the local application of chemical agents to contusions. Although no claims are made for these, it would appear just as well to eliminate them entirely. Important subjects such as burns and wounds have been covered splendidly and in proper detail. Chapter XXXI, dealing with the technic of numerous methods of hospital care, including fluid administration and transfusion, should be particularly valuable to the intern. This material has been made up to date, even including a short discussion on the Rh factor in blood grouping and blood transfusions. The reviewer agrees that the limitation of the discussion on bandaging to five or six pages is appropriate. Chapter XXIV, dealing with preoperative and postoperative care, is likewise particularly valuable to the surgical intern but could be read profitably by any surgeon. The last chapter, which has been directed primarily to the intern, includes discussion on the conduct and responsibilities, which are seldom considered in medical literature. This book continues to be one of the best in the field and can be read profitably by any one in the medical profession.

The Adrenal Glands in Health and Disease. By Max A. Goldzieher, M.D., Endocrinologist, St. Clare's Hospital, New York City. Fabrikoid. Price, \$3. Pp. 727, with 81 illustrations. Philadelphia: F. A. Davis Company, 1944.

This volume, written by a man who has devoted most of his professional lifetime to a study of the adrenal glands, is of real value to any student in clinical endocrinology or clinical pathology. There has been an interval of eight years since a comprehensive treatise on the adrenals by Grollman was published. During that time much new investigative work and clinical experience in the management of Addison's disease has appeared. In the current volume the author has presented a careful documentation of the entire field and has studied the adrenal cortex and medullas from the points of view of embryology, anatomy, physiology, biochemistry and clinical management of disorders of the glands. His own points of view are presented with modesty and without failing to point out differences of opinion and the points of view which are held by numerous other modern students in this field. In the sixty chapters of this book one will find discussion of correlation between the adrenals and almost any aspect of physiology or of clinical medicine which can be considered significant in any way. References to the literature are given chapter by chapter, with definite reference to the authority for all questionable statements. A twenty-three page index adds greatly to the usefulness of the book. The paper, the typography and the reproductions of the illustrations are excellent. The author is to be congratulated on an enormous task well done.

Six Thousand Years of Bread: Its Holy and Unholy History. By H. E. Jacob. Cloth. Price, \$4.50. Pp. 399, with 63 illustrations. Garden City, New York: Doubleday, Doran and Company, Inc., 1944.

Man must eat to live. In his desire to survive, the word "bread" has become synonymous with survival. This book gives the story of bread in its religious, political and technical aspects over a period of six thousand years. The author consulted a vast bibliography. His record of six thousand years ends with

a recognition of the necessity for feeding a starving world in the postwar period if mankind is to survive. No better quotation could be selected to indicate the significance of this work than that from ex-President Hoover, who said in May 1943 "The first word in a war is spoken by the guns—but the last word has always been spoken by bread."

The Brush Foundation Study of Child Growth and Development. I: Psychometric Tests. By Elizabeth Ebert & Katherine Simmons. Monographs of the Society for Research in Child Development, Volume VIII, No. 2 (Serial No. 35). Paper. Price, \$1.50. Pp. 113, with 19 illustrations. Washington, D. C.: Society for Research in Child Development, National Research Council, 1943.

This is the first of a series of reports of a study of growth and development of children, originally organized and directed by T. Wingate Todd. Periodic examinations, including psychometric tests, anthropometric determinants and roentgenograms, have been made. A selected group of presumably "normal" (probably, as a group, "superior") children were examined between the ages of 3 months and 15 years. The report covers ages 2 to 15 years. Constancy of intelligence tests, constancy and relation of performance tests to tests of intelligence, the prediction of scholastic achievement by earlier psychometric tests, and sibling resemblances are reported. To select items of clinical interest, it is reported, "there are children whose mental test standard scores show decided decelerating trends and accelerating trends which apparently are independent of test standardization and peculiar to the individuals." Further, a superior intelligence quotient does not offer assurance that educational achievement will be at a correspondingly high level. These observations point toward problems of psychiatric import not otherwise dealt with in the study. This important study, in the form published, is of interest to the research worker in child development; one will await with interest clinical elaboration in connection with the later studies of the series.

The Jews and Medicine: Essays. By Harry Friedenwald, M.D., D.H.L., D.Sc. Volumes I and II. Publications of the Institute of the History of Medicine, The Johns Hopkins University, First Series, Monographs, Volumes II and III. Cloth. Price, \$3.75 per volume. Pp. 390; 391-817, with 40 illustrations. Baltimore: Johns Hopkins Press, 1944.

These two volumes represent the collected essays of a distinguished medical historian and scholar. Many of the essays have previously appeared in the *Bulletin of the History of Medicine* from the Johns Hopkins Institute of Medical History and others in a wide variety of medical publications, such as the *Annals of Medical History*, the *Medical Pickwick*, *Medical Life* and *Medical Leaves*. For those especially interested in the field concerned, it is delightful to have these collected essays readily available. Particularly valuable is the list of eminent Jewish physicians of the Middle Ages, with brief biographic notes and bibliography.

Ventilation and Heating: Lighting and Seeing. Conditions for Industrial Health and Efficiency Pamphlet No. 1. Issued by the Industrial Health Research Board of the Medical Research Council. Paper. Price, 3d. Pp. 20, with 11 illustrations. London: His Majesty's Stationery Office, 1943.

This pamphlet outlines the main facts known about ventilation, heating, lighting and seeing that should be applied to industrial establishments. It is written in a nontechnical manner for the industrial manager or worker to aid primarily in the problems arising from complete blackout of plants in England. The presentation describes practical procedures that may be used in any installation.

The Use of Penicillin in Treating War Wounds. (Instructions Prepared by the Penicillin Clinical Trials Committee). Medical Research Council, War Memorandum No. 12. Paper. Price, 10 cents; 3d. Pp. 16. New York: British Information Services; London: His Majesty's Stationery Office, 1944.

This pamphlet was prepared by the Penicillin Clinical Trials Committee of England for the purpose of providing instructions for the use of penicillin in war wounds. It contains an adequate outline of the methods of administration and preparation of penicillin for clinical use, and specific instructions are given for its application in various types of wounds. The content is sound and accurate. Every one interested in penicillin will profit from reading this booklet.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PRESENT MORTALITY RATES OVER AND UNDER AGE OF FIFTY

To the Editor:—Recently I saw a statement that the mortality rate at persons over 50 years of age had increased 10 per cent since the declaration of war and that even with the casualties in the battle zones or with all war casualties the mortality rate of the younger people, or those under 50, has remained approximately the same. Are there definite statistics concerning this?

D. D. Sanderson, M.D., Lincoln, Neb.

ANSWER.—According to the provisional mortality figures of the United States Bureau of the Census based on a 10 per cent sample of death certificates, there has been an increase of a little over 4 per cent in the death rate for the population 50 years and over in 1943 as compared with the corresponding rate for 1941. The mortality rate for the age group under 50 years showed a slight decrease in 1943 from the corresponding rate in 1941. These comparisons do not include deaths among military personnel occurring outside the continental United States. Although exact data on war casualties are not available, the relative increase in the death rate for the population under 50 years of age would probably not be greater than the 4 per cent increase observed for the age group 50 years and over if deaths among American soldiers abroad are taken into consideration.

AUTONOMOUS BLADDER AFTER SECTION OF NERVE ROOTS

To the Editor:—An exploratory operation on the sacral canal to determine the cause for intractable sciatic pain was performed about ten months ago on a woman aged 62. The only condition of a pathologic nature found was a chronic inflammation of the nerve roots. The second and third sacral roots on the left and the second sacral root on the right were severed. Following the operation, urinary incontinence developed. For the past two months the incontinence has ceased while the patient is in bed. However, on assuming the erect posture, there is an almost immediate flow of urine. The bladder does not seem to be completely paralyzed, since the patient can voluntarily express urine. A cystocele is present; residual urine analysis, which at first showed innumerable white cells, has been normal for the past three weeks. Catheterization, which was practiced frequently some months ago, has been discontinued. May I have an opinion concerning the prognosis and treatment?

M.D., New York.

ANSWER.—The results of the exploratory operation are similar to those which follow complete section of both pelvic nerves. The result is similar to that found in a lesion of the conus medullaris, or reflex center of the sacral cord. The present condition may be described as an autonomous bladder. It is difficult to make an accurate diagnosis from the data given without determining the amount of residual urine remaining in the bladder after the patient has strained to void all that is possible. It would be advisable to empty the bladder with a catheter and later determine how long the patient can hold the urine before the so-called incontinence appears. The incontinence might be an overflow incontinence. It is also suggested that cystoscopy be made to determine whether or not the bladder is hypertonic and trabeculated, as it should be with an autonomous bladder. It seems hardly probable that the cystocele is a factor in the patient's condition.

If such a condition is present, about the only thing that could be done would be to train the patient to void at intervals, using abdominal straining and manual compression of the bladder. In this way the amount of urine in the bladder could be kept below the level at which the so-called incontinence occurs. Should secondary infection be present, sulfonamide medication at intervals may be indicated.

BURNS AND RHEUMATOID ARTHRITIS

To the Editor:—In a case of infective arthritis following severe burns a claim has been filed. I would appreciate any reference in the literature to sequelae of this nature following burns.

D. J. Fraser, M.D., Winnipeg, Man.

ANSWER.—A severe burn might operate in two ways to induce arthritis: (1) by virtue of the excessive demands made on the central defense mechanism of the body and (2) by virtue of the secondary infection which develops on the burned surfaces. In rheumatoid or atrophic arthritis, infection may act as a precipitating factor and the modern view is that the arthritic

phenomena probably represent a psychosomatic reaction, presumably through the mediation of the neuroendocrine system. In the present war cases of rheumatoid disability are developing on the apparent basis of the strain and tension involved in army service. In the last war, exposure and such conditions as dysentery induced rheumatoid arthritis, which sometimes developed only after considerable delay. It is worthy of note also that in the last war patients who developed arthritis gave a history of previous attacks with a frequency five times greater than was observed in cases admitted to the medical service at large. A severe burn can therefore be regarded as a precipitating factor, acting on soil presumably somewhat susceptible to rheumatic disease to produce the full picture of rheumatoid arthritis.

IMMEDIATE TREATMENT OF CARBON TETRACHLORIDE INGESTION

To the Editor:—A woman aged 40 drank a large amount of carbon tetrachloride fluid. She was immediately given gastric drainage and lavage, and this was followed by saline cathartics. Our question is, as this substance is highly soluble in oils, could liquid petrolatum be given to the patient? My associates feel that the oil is so poorly absorbed that it would be evacuated before significant absorption has occurred. However, I believe that there is considerable absorption as evidenced by the oil in the lymph glands of the mesentery as seen on autopsy, especially in those who have had considerable quantities at one time or for some period of time.

David E. MacQuigg, M.D., Albany, N. Y.

ANSWER.—Liquid petrolatum is effective in decreasing gastric absorption of carbon tetrachloride only if it is administered promptly. If any considerable time elapses between the swallowing of carbon tetrachloride and the administration of liquid petrolatum, little antidotal effect can be expected. In any event it is important to wash out the stomach thoroughly, employing oils such as liquid petrolatum or vegetable oils (olive oil, cottonseed oil, salad oil) and to follow gastric lavage with a saline cathartic. The administration of liquid petrolatum only shows absorption of carbon tetrachloride, and any of the poison which has passed the pylorus will unquestionably be absorbed in spite of the use of oily antidotes.

CONCEPTION AFTER ECTOPIC PREGNANCY

To the Editor:—What successes or failures in becoming pregnant have been achieved following ectopic pregnancy which has necessitated removal of one ovary and tube? What are the percentages of recurrences of ectopic pregnancy?

M.D., New York.

ANSWER.—Statistics from various clinics indicate that among women who have had one tube and ovary removed because of ectopic gestation (that is, in whom there is a theoretical possibility of future conception), about 35 per cent subsequently become pregnant. Of those who do have a subsequent pregnancy, 10 to 15 per cent have another ectopic pregnancy. Stated differently, among 100 women who have had one tube and ovary removed because of ectopic gestation, about 65 women would not conceive at all, about 30 would become pregnant with normal intrauterine gestations, while 4 or 5 would experience another ectopic pregnancy.

CHRONIC UNDULANT FEVER

To the Editor:—Has penicillin been used successfully in the treatment of undulant fever? What seems to be the most satisfactory treatment for this disease? The patient is ambulant, has an afternoon fever and complaints of lassitude and weakness; she has been in this stage for about two years but has been slightly worse lately.

Leonard Nelken, M.D., Clinton, Iowa.

ANSWER.—Penicillin has had no effect on the course of undulant fever. There is no really satisfactory treatment for this disease. Occasionally, sulfadiazine has been found beneficial. An effort should be made to discover a chronic focus of infection, particularly in the biliary tract, which would be amenable to surgical treatment. Some consideration should be given to the possibility that the patient's symptoms are caused by some other disease.

THERAPY FOR COLD HANDS AND FEET

To the Editor:—In the June 3, 1944 issue of The Journal there was on page 390 an inquiry about cold hands and feet in a girl aged 19. I agree with the answer as far as the neurologic differential diagnosis is stressed. The cervical rib, Raynaud's syndrome and thromboangitis obliterans should always be excluded. Assuming that the results are negative, however, it would not begin by considering cervical sympathectomy. One should begin with one of the following: relaxation therapy as described by Edmund Jacobson, 1938, University of Chicago Press, wake suggestion or hypnosis. The first two may be used as a preliminary for the third, if necessary. The results are encouraging and lasting, and they can be reached without even taking the patient to a warmer climate. The same, incidentally, holds for cold feet and neurotic red ears and hot head in younger persons.

Wladimir Eliasberg, M.D., New York.

ENDEMIC EXUDATIVE PHARYNGITIS AND TONSILLITIS

ETIOLOGY AND CLINICAL CHARACTERISTICS

COMMISSION ON ACUTE RESPIRATORY DISEASES

During the course of studies at the Regional Hospital at Fort Bragg, it was noted that approximately 10 per cent of all patients admitted for respiratory disease had exudate in the pharynx or on the tonsillar tissue. Some of these patients exhibited both clinical and bacteriologic evidence of beta-hemolytic streptococcus pharyngitis; some had beta-hemolytic streptococci in their throats but the clinical picture was not characteristic, and others had neither clinical nor laboratory evidence of beta-hemolytic streptococcus infection. These findings were at variance with commonly held beliefs that the beta-hemolytic streptococcus is the commonest cause of exudative pharyngitis and tonsillitis and that a characteristic clinical picture is associated with the presence of exudate in the throat.¹ It therefore seemed of importance to undertake a systematic clinical and laboratory study of the problem. Since beta-hemolytic streptococci may be harbored in the throats of healthy persons as well as in those suffering from colds and other types of respiratory illness, the diagnosis of streptococcal pharyngitis rests secure only when a specific antibody response to the organism can be demonstrated during convalescence.

One hundred and sixteen cases of exudative tonsillitis and pharyngitis were studied. In 25 per cent of the cases, beta-hemolytic streptococci were found

and a rise in streptococcus antibodies was demonstrated in the serums in convalescence. In these cases beta-hemolytic streptococci clearly contributed to, or were responsible for, the clinical condition. In another 25 per cent of cases beta-hemolytic streptococci were found but a rise in antibodies did not occur. In most of these cases there was considerable doubt as to the etiologic significance of the organism. In slightly more than 50 per cent of all cases streptococci were not found on repeated cultures, and in these cases there was little evidence that bacteria were etiologic agents.

Well defined clinical differences were demonstrated between those patients who harbored streptococci and developed antibodies and the other two groups of patients. The latter two groups were, in general, similar to each other in clinical characteristics.

MATERIALS AND METHODS

Source of Cases.—The study was confined to patients who were admitted from selected organizations to the Regional Hospital at Fort Bragg during a ten week period from April to June 1943. The criterion employed for deciding when a soldier required hospitalization was, in general, a temperature of 100 F. (oral) or higher at the time of reporting to the dispensary. Altogether, 900 soldiers from the selected organizations were admitted to the hospital for respiratory symptoms during the period of the study.

The patients were examined within a few hours after admission, and all who had exudate in their throats at that time were included in the study. The presence of exudate at the time of initial examination was the sole criterion for the selection of cases.

Clinical Methods.—The history and physical findings were elicited and recorded in a uniform manner. An attempt was made to date the onset of the illness accurately, to elicit the symptoms and physical signs every day, and to grade their severity.

Codeine was given for symptomatic relief in doses not exceeding one-half grain (0.032 Gm.), but antipyretic drugs were not used. Sulfonamide drugs were administered to a few patients according to clinical indications. Blood samples were obtained on all patients at the time of initial examination and again at approximately four weeks after the onset of illness. Total and differential leukocyte counts were made routinely soon after admission to the hospital, and subsequently as often as indicated.

Bacteriologic and Serologic Procedures.—Swab cultures of the throat were made daily for three successive days, beginning at the time of the first examination of the patient. An effort was made to include in the swabbing the surface of both tonsils or tonsillar fossae, the posterior pharynx and especially surfaces containing exudate. Cultures of the nose and nasopharynx were not taken.

From the Respiratory Diseases Commission Laboratory, Regional Hospital, Section 2, Fort Bragg, North Carolina.

The Commission was assisted by the technical staff of the laboratory, consisting of Marguerite Buckingham, Walter A. Mickle Jr., 2d Lieutenant, Sn. C., Barbara A. Mulliken, Thomas J. Oliver, 1st Lieutenant, Sn. C., Ralph L. Robinson, 1st Lieutenant, Sn. C., and Edith E. Searles.

Members of the Commission on Acute Respiratory Diseases are J. H. Dingle, Major, M. C., A. U. S., Director; T. J. Abernethy, Major, M. C., A. U. S.; G. F. Badger, Captain, M. C., A. U. S.; J. W. Beard, M.D.; N. L. Cressy, Major, M. C., A. U. S.; A. E. Feller, M.D.; A. D. Langmuir, Captain, M. C., A. U. S.; C. H. Rammelkamp, M.D., and E. Strauss, Captain, M. C., A. U. S.

This investigation was supported through the Commission on Acute Respiratory Diseases, Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, Preventive Medicine Service, Office of the Surgeon General, United States Army, and by grants from the Commonwealth Fund, the W. K. Kellogg Foundation, the John and Mary R. Markle Foundation and the International Health Division of the Rockefeller Foundation to the Board for the Investigation and Control of Influenza and Other Epidemic Diseases for the Commission on Acute Respiratory Diseases.

The following officers and their staffs at Fort Bragg assisted the Commission on Acute Respiratory Diseases and made this study possible: Major Gen. D. C. Cubbison, commanding general, Field Artillery Replacement Training Center; Brig. Gen. H. C. Coburn Jr., M. C., surgeon, Fort Bragg; Col. G. D. Chunn, M. C., commanding officer, Regional Hospital; Lieut. Col. W. B. Daniels, M. C., chief of medical services; Lieut. Col. H. O. Brown, M. C., chief of x-ray services; Lieut. Col. F. J. Pohle, M. C., chief of laboratory services; Major R. L. Siegel, M. C., surgeon, Field Artillery Replacement Training Center; Capt. A. H. Green Jr., M. C., admitting officer, Regional Hospital; Capt. H. E. McConnell, assistant admitting officer, Regional Hospital, and the following ward surgeons: Major T. T. Jones, M. C., Capt. R. D. Patterson, M. C., Capt. W. S. Branuing, M. C., Capt. C. L. Royster, M. C., and 1st Lieut. L. Chunn, M. C.

Throat swabs were placed immediately in 3 cc. of broth or isotonic solution of three chlorides and returned to the laboratory, where the swabs were rotated mechanically or by hand in order to obtain mixing of the contents. A loopful of this material was then streaked by a uniform technic on the surface of a freshly made meat infusion agar plate containing 5 per cent horse blood. After twenty-four hours' incubation at 37 C., the plates were examined for beta-hemolytic streptococci and other organisms; the relative numbers of each kind of organism were estimated and a note made as to which organism, if any, was predominant. An organism was considered predominant if it constituted more than 50 per cent of all the colonies (of any kind) on the plate.

Grouping of beta-hemolytic streptococci was performed by the capillary tube precipitin technic, using commercial rabbit serums and bacterial extracts prepared by Fuller's method.² Typing was done by the capillary tube modification of the Lancefield method, using bacterial extracts prepared by Lancefield's method.³ Type specific rabbit serums⁴ as well as capil-

single throat culture yielded only reasonably complete information and that the frequency of positive cultures was increased by repeated swabbing.

Distribution of Beta-Hemolytic Streptococci by Groups and Types.—The beta-hemolytic streptococci isolated from 47 of the 56 cases were found to belong

Chart 1.—Antistreptolysin titers of acute and convalescent serums in 55 cases of exudative tonsillitis and/or pharyngitis in which beta-hemolytic streptococci were isolated. In 1 other patient who had streptococci in the throat, convalescent serum was not obtained. Titers are expressed as units of antistreptolysin per cubic millimeter of serum. Figures refer to number of cases. Area within diagonal lines represents changes between acute and convalescent serums considered not significant, i. e. less than two tube change in titer. Figures to right of diagonal area represent significant increases in titer in convalescent serums; figure to left, significant decrease in titer.

lary tubes and serum containers were supplied through the generosity of Drs. Homer T. Swift and Rebecca C. Lancefield.

The streptolysin O used in this study was prepared and kindly supplied by Dr. T. Duckett Jones. The test was a modification of the method of Hodge and Swift.⁵ The titers of acute and convalescent serums were determined simultaneously, and all tests were performed with the same lot of streptolysin. The titers were expressed as the reciprocals of the highest serum dilutions which neutralized completely 1 unit of streptolysin.

RESULTS

The 116 cases of exudative pharyngitis and tonsillitis could be classified into three groups on the basis of laboratory findings. When such a division was made, definite clinical differences among the groups were demonstrated.

Beta-hemolytic streptococci were found in one or more of three throat cultures in 56 (48 per cent) of the cases in this series (table 1). Of these 56 cases 76 per cent were positive in the first culture, 88 per cent in the first or second culture and 12 per cent only in the third culture. This would indicate that a

to group A. In 1 case the streptococci were members of group B, in 2 cases group C and in 1 case group H. In 5 cases the organisms isolated were not grouped.

Typing was accomplished successfully in 38 of the 47 cases with group A strains; 9 had strains which were not typed with the serums available. The type distribution was as follows: type 3, 6 cases; type 5, 4 cases; type 19, 9 cases; type 26, 4 cases; types 12, 33 and 45, 2 cases each; and types 6, 9, 18, 32, 39 and 44, 1 case each. In addition, three cross reactions which could not be separated further, namely 33 and 26, 17 and 26, and 19 and 33, were each encountered once.

Antistreptolysins.—The antistreptolysin levels of acute and convalescent serums are shown in chart 1 for patients with beta-hemolytic streptococci and, for

Chart 2.—Antistreptolysin titers of acute and convalescent serums in 60 cases of exudative tonsillitis and/or pharyngitis in which beta-hemolytic streptococci were not isolated. See explanation in legend of chart 1.

patients without streptococci, in chart 2. As the test was performed, a two tube change in titer may be considered as beyond the limit of technical error.⁶ A rise in titer of two tubes or more was arbitrarily considered to indicate a significant increase in antibodies.

3. Swift, H. F.; Wilson, A. T., and Lancefield, R. C.: J. Exper. Med. 78: 127, 1943.
4. Typing serums were available for types 1, 2, 3, 4, 5, 6, 9, 12, 13, 14, 15, 17, 18, 19, 23, 26, 28, 29, 30, 31, 32, 33, 36, 37, 39, 41, 43, 44, 45 and 46.
5. Hodge, B. E., and Swift, H. F.: J. Exper. Med. 58: 277, 1933.

6. Mote, J. R., and Jones, T. D.: J. Immunol. 41: 61, 1941.

Of the 56 patients who harbored beta-hemolytic streptococci, 28, or 50 per cent, developed a rise in antistreptolysin titer of two tubes or more. Of the 60 patients who had no beta-hemolytic streptococci in any of the three throat cultures taken, only 1 showed a similar rise in titer. In this instance there was strong circumstantial evidence that the patient contracted a streptococcal infection after he passed from observation in the hospital and before the second blood specimen was obtained. The almost complete consistency with which an antibody response was demonstrated only in patients in whom beta-hemolytic streptococci were found may be considered evidence of the validity of the cultural methods.

The average interval between onset of illness and the time of convalescent bleeding was four weeks, and this interval was the same for those who did and for those who did not show a rise in antibodies. In 22 of 28 patients the rise was three tubes or more, and in 18 patients the rise was four tubes or more. There were 2 instances of a two tube fall in titer between acute and convalescent serums. While these changes were probably significant, they were most likely due to an infection with beta-hemolytic streptococci that occurred prior to the present illness.

A considerably greater proportion of the cases with streptococci showed a one tube rise in antistreptolysin than was evident in the nonstreptococcus cases. It is entirely reasonable that some of the cases which were regarded as having no antibody response actually had a response which differed only quantitatively from that of the group which was considered to have a significant rise in antibodies. Other evidence of a clinical nature will be presented which tends to bear out the assumption that some of the cases which had no significant antibody response were otherwise similar to those cases which did. The majority of cases in this category, however, closely resembled those of nonstreptococcal sore throat.

The range of antistreptolysin titers which are regarded as normal is variable. It is generally considered, however, that a titer of 250 units or more is elevated, while a titer lower than this is normal.⁷ When only a single serum is available from each patient, such criteria must be used; but when both acute and convalescent serums are available it seems more reasonable to record a change in titer. It can be seen in chart 1 that 7 patients whose titer of antistreptolysin in the convalescent serums was less than 250 had a rise of two tubes or more when compared with the levels of their acute serums; in 3 patients the convalescent titer was 100 or less. If only convalescent serums had been available, none of these patients would be considered as having developed antibodies. When these titers were compared with those of the acute phase serums, however, a change was shown which was believed to be significant.

In 2 cases in which only group C beta-hemolytic streptococci were isolated a significant rise in antistreptolysin titer developed. In all the other cases in which a two tube rise was demonstrated, group A strains were isolated from the throat cultures.

Relation of the Number of Organisms to Development of Antibodies.—Of 56 cases with beta-hemolytic streptococci, the organisms were present in predominance in 21 (table 2). When the cases were divided

according to whether or not there was a demonstrable rise in antistreptolysin titer of the serums, it was found that in more than two thirds of the cases in which streptococci predominated antibodies developed, while in two thirds of the cases in which streptococci were present but not predominant antibodies did not develop. The figures indicated that antibodies were more likely to develop in those cases in which streptococci were numerous, but it was also evident that a considerable number of cases in which streptococci were not numerous might still respond to the antigenic stimulation of the organisms.

Similar conclusions were reached from the data presented in table 1. This table shows that antibodies developed more frequently in those cases in which two or more throat cultures contained beta-hemolytic streptococci than in cases in which the organisms were isolated in only one of three throat cultures. Whereas streptococci were present in two or more throat cultures in 93 per cent of the cases in which antibodies were present, streptococci were isolated from two or more cultures in only 64 per cent of the cases in which antibodies did not develop. This may be considered as further evidence that the organisms present in many of the cases in the latter group were transient and not intimately related to the clinical disease.

TABLE 2.—Relation of the Number of Beta-Hemolytic Streptococci in One or More of Three Throat Cultures to the Development of Antibodies

No. of Organisms	No. of Cases With Antibody Rise	No. of Cases Without Antibody Rise	Total
Present (not predominant).....	13	22	35
Predominant.....	15	6	21
Total.....	28	28	56

Other Laboratory Studies.—The results of other bacteriologic and serologic studies yielded information chiefly of negative value. In addition to beta-hemolytic streptococci, *Haemophilus influenzae*, *Haemophilus haemolyticus*, *Staphylococcus aureus* and pneumococci were found with the same frequency as in normal throats.⁸ The pneumococci were of the "carrier" types that are characteristic of normal persons.⁹ Pneumococcus agglutinins which could be considered significant were found in the serum of only 1 of 20 patients who harbored these organisms.

CLINICAL OBSERVATIONS

In the total series of 116 cases of exudative tonsillitis and/or pharyngitis the additional diagnosis of measles was made in 3 cases and of scarlet fever in 5 cases. There were also 14 cases in which clinical and roentgenographic evidence of pulmonary infiltration developed. With the exception of the latter, most patients had a short febrile course and a rapid recovery. Blood cultures were taken on 19 of the most severely ill patients; in all instances they were sterile. Complications were rare; 3 patients had peritonsillar cellulitis

but none required surgical drainage, and 1 patient developed suppurative otitis media. None of the patients showed the clinical characteristics of Vincent's angina.

Constitutional Symptoms.—In chart 3 are shown the time of onset of specified constitutional symptoms in

Chart 3.—Onset of specified symptoms. Cumulative frequency by day of disease. Solid lines represent cases of beta-hemolytic streptococci in which antibodies developed; broken lines, cases of beta-hemolytic streptococci in which antibodies did not develop; dotted lines, cases in which there were no beta-hemolytic streptococci. Same symbols used in subsequent charts.

relation to the onset of the disease. These graphs indicate the cumulative frequency of each symptom in relation to the total number of cases in each group included in the analysis. The relationship of the curves of the three groups to one another remained fairly constant for each symptom. It will be seen that, in every instance, symptoms developed more rapidly and occurred in a greater proportion of patients in the group who developed streptococcus antibodies than in

Chart 4.—Frequency of specified symptoms by day of disease. The following rules were used in calculating the percentage frequencies in charts 4, 5, 6 and 7: 1. Patients discharged from the hospital with a specified symptom or sign not present were considered to remain free from that symptom or sign thereafter. 2. Late in the course of illness patients were frequently discharged with a symptom or sign still present. Points were not plotted when this fact made the indicated relationships inaccurate.

the group without streptococci, or with streptococci but without antibodies. The last two groups seemed to be more nearly alike and to be quite distinct from the first.

In chart 4 are depicted the frequencies with which individual symptoms occurred in proportion to the total number of cases in each group by twelve and twenty-four hour periods throughout the disease. Here again there was a rather consistent pattern in each of the three groups, and the relationship of the curves to each other remained the same for each symptom. In the group of streptococcal cases in which antibodies developed, the maximum frequency of symptoms occurred within twenty-four hours of the onset of the disease, while in the other two groups, particularly in the cases in which streptococci were not present, the maximum frequency of symptoms occurred later in the illness.

Localizing Symptoms.—The frequency with which specified localizing symptoms occurred in proportion to the total number of cases in each group by twelve and twenty-four hour periods from the onset of illness is shown in chart 5. As would be expected, soreness of the throat was present in the great majority of cases. It occurred with maximum frequency earlier (within twenty-four hours) in the group of cases with antibodies than in either of the other two groups.

Chart 5.—Frequency of specified symptoms by day of disease.

Cough and hoarseness showed a frequency distribution quite different from soreness of the throat. These two symptoms are not ordinarily considered as essential features of streptococcal sore throat, and although they occurred in about half of the cases in the group they were much more frequent in the cases in which streptococci were not present. The latter group of cases resembled undifferentiated respiratory disease in many ways. The tendency toward more diffuse involvement of the respiratory tract, as indicated by the frequency of cough and hoarseness and the lesser frequency of soreness of the throat, may be considered evidence in favor of this point of view.

Physical Signs.—The important physical signs present in the throat are depicted in charts 6 and 7, which show the frequency of a given sign in relation to the total number of cases in each group under observation on each day, beginning with the second day of disease. In the over all daily frequency of various signs there were no significant differences among the three groups of cases, but, when total frequency was compared with the frequency of severe or intense signs, significant differences became apparent. For example, injection of the tonsils or of the soft palate occurred with equal frequency in all three groups of cases. Diffuse injection of these tissues, however, was twice as frequent

in the cases in which streptococci and antibodies were present as in the other two groups of cases. Similar differences in severity were shown in regard to edema of the uvula, exudate on the tonsils and injection of the pharynx. In general, all of these physical signs were most frequent at the time of the first examination.

Chart 6.—Frequency of specified physical signs by day of disease. Light lines represent total frequencies; heavy lines, frequencies of pronounced or severe degrees of specified physical signs.

There was but little evidence that new signs appeared in the throat or that signs progressed in intensity after the second day of illness. In contrast to the other physical signs in the throat, the presence of hyperplastic lymph follicles in the pharynx was more common in pharyngitis not associated with beta-hemolytic streptococci than in cases associated with streptococci. It has been noted that hyperplastic lymph follicles on the posterior pharyngeal wall are commonly found in cases of undifferentiated respiratory disease and atypical pneumonia. It was also noted that hyperplastic lymph follicles were more prominent and more common in patients who had no tonsillar tissue than in those who had.

The clinical impressions made at the time the patients were seen in the hospital were compared with the final diagnoses arrived at on the basis of bacteriologic and serologic evidence. Without prior knowledge of

Chart 7.—Frequency of specified physical signs by day of disease. Based on number of patients who had tonsils or tonsillar tags. See symbols in chart 6.

laboratory results, the examiners attempted to predict whether or not beta-hemolytic streptococci would be found in each case. In the 60 cases in which no streptococci were found, the clinical prediction was correct in 50 cases and equivocal in 6, while only 4 cases were erroneously considered instances of "streptococcal sore throat." It was evident that the clinical picture

of nonstreptococcal sore throat was usually quite easily distinguished from that of streptococcal sore throat. There was likewise no difficulty in recognizing the fact that cases in which streptococci were present but no antibody rise developed did not present the physical findings of "streptococcal sore throat." Only 15 per cent of the cases in this group were mistakenly considered instances of the latter. On the other hand, the clinical prediction of "streptococcal sore throat" was made correctly in only two thirds of the patients who developed streptococcus antibodies and was considered possible in an additional 15 per cent of such patients, while in 20 per cent it was thought most unlikely that streptococci were present.

Leukocyte Count and Maximum Temperature.—The cases in which streptococcus antibodies developed had a total leukocyte count which averaged 16,000 on the first or second day of disease, while for the other two groups of cases the average initial white count at the same time was 9,000. After the fourth day of illness there were no significant differences in any of the

TABLE 3.—Relationship of the Number of Beta-Hemolytic Streptococci Present in One or More of Three Throat Cultures to the Maximum Amount of Exudate Observed During Hospital Course in 116 Cases of Exudative Tonsillitis and/or Pharyngitis

	Amount of Exudate					
	Pinpoint		Discrete		Confluent	
	Number	Per Cent	Number	Per Cent	Number	Per Cent
Beta-hemolytic streptococci...	10	33	24	55	10	70
Present (not predominant)	11	23	17	39	7	31
Predominant.....	5	10	7	10	9	39
No beta-hemolytic streptococci	33	67	20	45	7	30
Total.....	49	100	44	100	23	100

three groups. The same relationships held for total polymorphonuclear leukocyte determinations and for the percentage of polymorphonuclear leukocytes. When streptococci were present but did not stimulate an antibody response, they likewise did not produce an elevation of the total or polymorphonuclear leukocyte count.

Little difference was found in the average maximum temperature on each day of disease among the three groups of cases.

Correlation of Presence of Tonsillar Tissue and Extent of Exudate with Presence of Streptococci and Development of Streptococcus Antibodies.—It is a common impression that streptococcal sore throat is more likely to occur in persons who have tonsils than in those who have had a tonsillectomy.¹⁰ In this study beta-hemolytic streptococci were found with equal frequency in those patients who had no tonsillar tissue and in those who had tonsils or tonsillar tags. Moreover, streptococcus antibodies developed with equal frequency in the two groups of cases.

A correlation was demonstrated between the amount of exudate in the throat and the presence and numbers of beta-hemolytic streptococci (table 3). Two thirds of the cases in which the exudate consisted of tiny flecks (pinpoint) did not exhibit beta-hemolytic streptococci, and in less than one third of those cases of pinpoint exudate in which streptococci were present were they predominant. However, 70 per cent of the

10. Bloomfield, A. L., and Felty, A. R.: Definition of Hemolytic Streptococcus Parasitism in Upper Air Passages of Healthy People, Arch. Int. Med. 32: 386 (Sept.) 1923. Bloomfield and Felty.¹² Finland.

cases in which the exudate was extensive and confluent showed the presence of streptococci, and of these more than half had the organisms present in predominance. Similarly, streptococcus antibodies developed more frequently in cases with large amounts of exudate than in cases with small amounts of exudate. It was apparent that while exudate in the throat may be associated with or caused by agents other than beta-hemolytic streptococci, extensive exudate was more likely to be associated with the presence of large numbers of these organisms, capable of stimulating the formation of antistreptococcus antibodies. In the absence of streptococci, exudate tended to be pinpoint or small in extent.

Relation of Types of Beta-Hemolytic Streptococci to Clinical and Immunologic Response.—A comparison of

TABLE 4.—*Immunologic Response, Clinical Diagnosis and Distribution of Cases According to Types of Group A Beta-Hemolytic Streptococci Isolated*

Type of Group A Beta-Hemolytic Streptococcus	Case Number	Anti-Streptolysin Change *	Clinical Diagnosis
3	34	0	Streptococcal sore throat, severe
	41	3	Streptococcal sore throat, severe

* Number indicates number of tubes increase in titer between acute and convalescent serum.

all cases in which the same type of group A strain was isolated revealed a number of interesting points (table 4). In all the 6 cases in which type 3 was found, antistreptolysins developed in high titer. Moreover, in 5 of the 6 cases the clinical diagnosis was scarlet fever or a severe streptococcal sore throat. It was evident that the type 3 organism was rather virulent and invasive and capable of stimulating antibody formation. To a lesser extent the behavior of the type 5 organisms appeared to be somewhat like that of the type 3 strains. On the other hand, the type 19 organism, which was found in 9 cases, seemed to be lacking in virulent or invasive qualities, since only 1 patient infected with this type of beta-hemolytic streptococcus had a clinically recognizable "streptococcal sore throat," and only 3 of the 9 patients developed a rise in antibodies. The type 26 organisms were of interest, since 5 of the 6 patients infected with this organism were admitted from one battery of 250 men. This was the only instance of focal concentration of cases noted in

the study. The patients were admitted to the hospital over a period of six weeks and had, in general, mild but clinically recognizable streptococcal infections. The organism was apparently not especially potent in stimulating an antibody response.

COMMENT

This study was undertaken for the purpose of investigating the etiology and clinical characteristics of cases of exudative tonsillitis and pharyngitis, especially with regard to the importance of beta-hemolytic streptococci. Such organisms were found in 50 per cent of the cases studied. This frequency is from three-to five times greater than has been found in a normal population of the same age group or in patients with respiratory disease without pharyngeal exudate.¹¹ In contrast, previously published studies have indicated that beta-hemolytic streptococci were almost invariably found in cases of exudative tonsillitis.¹²

It is believed that the results of a study such as this more closely approximate the situations met in the general practice of medicine than does the experience of civilian hospitals. In general, cases of mild endemic sore throat have been described. Since the chief criterion for hospital admission was a temperature of 100 F., most of these cases would not have been hospitalized in civilian life. Epidemic streptococcal sore throat was not encountered in this series.

Streptococcus antibodies developed in 28 of the 56 cases in which streptococci were present. The streptococcus etiology of these cases is regarded as certain, and hence they have been considered in a separate group and their clinical characteristics defined. The onset of this group of cases was more abrupt and, in the great majority, the maximal development of symptoms and physical signs was reached within twenty-four to forty-eight hours. In general, the symptoms were not more severe than those experienced by patients with nonstreptococcal sore throats, but characteristic differences were seen in the local physical signs. Pharyngeal and tonsillar mucosal injection was more intense and more diffuse, the degree of edema was greater and the exudate was more extensive in this group of cases. Wide variations in this pattern were apparent, however, and it seemed impossible in many instances to make a clinical diagnosis of "streptococcal sore throat." It should be emphasized that tonsillar tissue need not be present, and exudate was not necessarily extensive. Beta-hemolytic streptococci were present in predominance in half of these cases and were more likely to be predominant in the cases showing the most extensive exudate. These exhibited a definite leukocytosis which was of value in separating them from cases of nonstreptococcal sore throat, and particularly from cases in which streptococci were present but antibodies did not develop.

In another 25 per cent of cases with exudate in the throat, beta-hemolytic streptococci were found but a significant rise in streptococcus antibodies did not develop during convalescence. It has been pointed out that more cases in this group showed a one tube rise in antistreptolysin titer than was found in the group

of cases in which streptococci were not present. It is likely, in some instances, that the difference between cases with streptococci with antibodies and without antibodies was quantitative rather than qualitative. Clinically, several cases were encountered which presented characteristic "streptococcic sore throats" and had streptococci in the throat cultures but did not develop a two tube rise in antibodies. It is known that some patients with scarlet fever do not exhibit a rise in antistreptolysin titer during convalescence.⁶ There is, therefore, no reason to believe that the "antibody" group was necessarily complete and that all cases in the "nonantibody" group are to be regarded *a priori* as belonging in a different category. Nevertheless, this separation has been made because there were a sufficient number of distinguishing points between the two groups of cases, such as well defined differences in symptoms and physical signs, in number and persistence of streptococci in the throat, and in total and differential leukocyte counts. In summary, it seems justifiable to conclude that in the majority of the cases without streptococcus antibodies the streptococci were not the primary cause of the exudate in the throat and may have had no more relation to the infection than any of the other bacteria normally present in the throat.

In the 50 per cent of cases in this series in which beta-hemolytic streptococci were not found, the etiology remains unknown. In these cases the illness was generally mild but the onset was rather acute and constitutional symptoms were present in the majority of cases. The pharyngeal and tonsillar exudate was rarely confluent, usually small in extent and most often pinpoint. There was a tendency for cough and hoarseness to develop, indicating perhaps that, whatever the causative agent, it affected a larger area of the respiratory tract than the oropharynx alone. Redness, injection and edema of the mucous membranes were present in the majority of instances but were rarely of severe degree. Prominent hyperplastic lymphoid follicles on the posterior pharynx were seen commonly. This type of sore throat appears to be closely related to the majority of cases of undifferentiated respiratory disease.

SUMMARY

One hundred and sixteen hospital patients having exudate in the pharynx or on the tonsils at the time of initial examination were studied. On the basis of laboratory data the following classification was made: 25 per cent of the patients had beta-hemolytic streptococci and exhibited a rise in titer of streptococcus antibodies during convalescence, 25 per cent of the patients had streptococci but did not develop antibodies, and 50 per cent of the patients had no streptococci. Definite differences were demonstrated between cases with antibodies and those without, in regard to mode and rapidity of onset, total frequency of symptoms, severity of certain physical signs and leukocyte count. Cases with beta-hemolytic streptococci which did not develop antibodies were similar in clinical characteristics to cases which did not exhibit streptococci. It is concluded that in approximately 25 per cent of the cases studied the exudate was caused by beta-hemolytic streptococci, while in 75 per cent of the cases the causative agent was unknown. Except for the presence of exudate, the latter group did not appear to differ from the great majority of cases of undifferentiated respiratory disease.

APLASTIC ANEMIA FOLLOWING TRINITROTOLUENE EXPOSURE

A REPORT OF THREE CASES

JAMES H. EDDY JR., M.D.

SHREVEPORT, LA.

As has been pointed out many times, trinitrotoluene is a toxic material and causes numerous symptoms and signs. Fortunately, the great majority of these are of minor consequence. The most frequent complaint of the handler of trinitrotoluene is a dermatosis. This is generally mild and usually confined to the hands. Next in frequency are gastric complaints with nausea, vomiting, a feeling of fullness and occasionally a rather typical peptic ulcer syndrome. Chest pain, cough and nosebleeds are complained of by relatively fewer workers. There are also two other pathologic changes caused by trinitrotoluene and these are of a much more serious nature. The first and more common of these is hepatitis. The second and much more disastrous result of exposure is aplastic anemia.

It would appear that in certain susceptible persons the bone marrow may be damaged by trinitrotoluene. It is suggested that individual predisposition is of principal importance because of the rare occurrence of this disease in spite of the great many workers exposed to trinitrotoluene in this war and the last. That the degree of susceptibility of the bone marrow is important will also be shown by the occurrence of this phenomenon in three workers whose environments showed a relatively low concentration of the toxic material. These men developed a fatal disease while in trinitrotoluene exposures that varied close to the maximum permissible limit of 1.5 mg. per cubic meter of air. It is also of interest to note that during the time of operation of this particular plant only 1 case of trinitrotoluene hepatitis has occurred.

The English literature has reported a number of cases of fatal aplastic anemia in munitions handlers.¹ The exposure, clinical picture and course have been not unlike those included here.

It is also true that the American munitions industry as a whole is seeing about as many fatal cases of aplastic anemia as of hepatitis. The mortality of this disease among the few cases observed has been high. I am informed that half of the first eight trinitrotoluene fatalities reported in American shell and bomb loading plants during the first 93,000 man-years of operations were cases of aplastic anemia.² In other plants, these cases have also occurred in places of relatively low trinitrotoluene concentration. One case of aplastic anemia followed recovery from hepatitis in England,³ but such a combination has not been seen in this country to my knowledge.

The age, physical characteristics, previous employment and other factors appear to have no bearing on the susceptibility in these cases.

The outstanding factor in these cases would appear to be exposure to trinitrotoluene dust and fumes for a

period of several weeks to several months. From experience gained in England, it has generally been felt that if an employee tolerates trinitrotoluene for as much as five or six months he is unlikely to suffer any dangerous consequences.³

It has not been possible to reproduce aplastic anemia in dogs with trinitrotoluene, and it has been incorrectly suggested by myself⁴ and others⁵ that it was likely that the so-called aplastic anemia was a final stage of the anemia so often seen in trinitrotoluene handlers and was due to blood destruction. That this is not true is well shown by the typical hypoplastic or aplastic appearance of the bone marrow in these cases as well as other recent ones.

In my experience the patient usually presents himself complaining of weakness and easy fatigue. He may state that he noticed a few purple spots and came in because he was curious about them. Sore mouth or respiratory complaints may be the only symptoms. A blood count which should be taken on any trinitrotoluene handler with such complaints will usually give an immediate indication of the severity of the disease. Sternal bone marrow biopsy should be done in cases showing suggestive blood pictures. This procedure will rule out aleukemic leukemia, agranulocytosis and

The prognosis is extremely grave, and most of the cases have run a very short course in spite of intensive treatment.

REPORT OF CASES

CASE 1.—A white man aged 26, who had been employed in the shipping room of a bomb line for several months, reported to the plant hospital on Dec 15, 1942 complaining of general malaise, aching pains and upper respiratory infection. Unfortunately no blood work was done and the patient was allowed to go home, where his family physician gave him 100 grams (65 Gm.) of sulfanilamide over a period of two days. He was also given elixir of phenobarbital and a "cold" capsule. After several days of this treatment he began having a sore mouth, and a dentist was consulted because it was thought that he had "trench mouth." The dentist stated that it was not a Vincent's infection and prescribed a mouth wash. He gradually became worse and was sent to a nearby hospital on Jan 2, 1943. Shortly after admission a few purpuric spots were noted over the lower extremities. These rapidly increased in number and occurred over the rest of the body. On the third day he had epistaxis, and the following morning he had tarry stools. During the hospital stay he was given several transfusions that resulted in severe reactions. He progressed rapidly downward, developed deep jaundice by the sixth day and died on the seventh. The laboratory findings are summarized in table 1. Autopsy findings of particular interest were confined to the bone marrow, kidneys and liver. Dr W R

Medication included pentnucleotide, liver extract and extract of yellow bone marrow

thrombocytopenic purpura, the three most likely confusing conditions. It is not likely that the bone marrow study will be of any prognostic significance in determining the cases of aplastic anemia in which survival will occur with careful treatment. By that I mean that, even though marrow destruction does not appear particularly extensive, death may follow rapidly in spite of frequent transfusions.

Treatment consists primarily in removal from contact with trinitrotoluene and other substances known to depress bone marrow and careful cleansing of the skin to remove traces of the poison. Support with frequent transfusions of fresh blood is of the greatest importance in prolonging life. Other therapeutic aids of somewhat questionable value include pentnucleotide in full doses of 40 cc daily, crude liver extract, extract of yellow bone marrow, a high vitamin, high caloric diet and scrupulous care of the mouth in hope of preventing infection. The use of concentrated or diluted cells is suggested and was used in 1 case. It solves the problem of obtaining blood if a plasma bank is near. The cells should be not over 24 hours old in order to receive the value of the short lived white cells. This is suggested as there is no lack of plasma in these patients. It is felt that this method should be given a further test.

Mathews, the pathologist, reported "The sternal bone marrow was brownish red but there was no marrow fluid on the cut surface on pressure of this tissue. Sections from the sternal marrow showed a marked degree of hypoplasia. In fact, for the most part they are devoid of marrow cells and are in an aplastic state. Areas of considerable size show nothing but fat and marked congestion of the sinusoids and capillaries. This last feature accounts for the predominantly red color exhibited by the marrow on gross examination. Both the erythropoietic and the leukopoietic elements are involved. The marrow cells remaining are of the mature or more mature types."

"The liver cells are more granular than normal and some of them are vacuolated. The latter change tends to occur around the central vein, where there is also necrosis. The necrosis is predominantly central but does occur to a less extent in the midzone . . ."

Dr. Mathews' comment on his findings is pertinent and is quoted in full. "The primary disease in this case was an acute form of aplastic anemia. It is not possible to suggest from these examinations whether this is a primary or secondary form of the disease. I mean, by secondary, anemia due to some agent such as benzol, trinitrotoluene or x-rays. The etiology would have to be established or excluded by history of exposure to one of the agents. It can be said that this patient's clinical features and the autopsy findings are perfectly consistent with the primary form, but, on the other hand, there are no inconsistencies on these bases for the secondary type."

"He developed terminal pneumonia and sepsis which was not unexpected in the presence of almost total disappearance of the granulocytes from the peripheral blood as well as from the marrow. This neutropenia was responsible for the development of the oropharyngeal ulcerations which I understand

existed and also let the gap down for invasion of the blood stream by perhaps a number of types of bacteria from the mucous surfaces, especially the oropharynx. Bacterial colonies were noted in sections from the lungs, spleen, lymph nodes and liver. The pneumonia was of the type that usually develops in the course of agranulocytosis—the exudate is devoid of polymorphonuclear leukocytes.

this patient had multiple blood transfusions, one has to consider the possibility of a transfusion reaction. Ordinary methods of testing for compatibility of blood to be transfused do not detect the presence of the Rh factor. Assuming that the patient was Rh negative and the donor Rh positive, one would have a set up that might eventuate in a transfusion (hemolytic) reaction. The changes in the kidneys and the focal necroses in

R. B. C. normal in appearance. W. B. C. mature. Patient receiving liver extract intramuscularly 2 cc. daily; pentnucleotide 10 cc. intramuscularly daily. Had cleansing bath to remove oil trinitrotoluene from skin, checked with skin webster. Sternal bone marrow biopsy showed an aplastic marrow on Oct. 16, 1943.

"The jaundice which developed during the last forty-eight hours of life is, in my opinion, mainly of the hemolytic type. The urine was negative for bilirubin but positive for urobilin and occult blood (benzidine test). Although there were focal necroses in the liver, one would expect some bilirubin in the urine provided the jaundice had been due to toxic hepatitis. A septicemia due to a hemolytic micro-organism (*Streptococcus haemolyticus*?) could have caused the jaundice. Also, since

the liver could be due to this cause. Of course, it is not possible to say from the sections whether the pigment casts in the renal tubules are hemoglobin or bile (bilirubin). There are no tests that differentiate these in fixed tissue specimens. The histologic changes may be identical in both."

CASE 2.—A white man aged 65 had been employed in a bomb line cooling bay for four months. He developed a respiratory infection in March that seemed of no consequence but lasted

several weeks. He took four Dasin capsules⁶ and compound infusion of senna during this time but no other medicine. He did not report this illness and resigned on March 30, 1943. During the first part of April he noted a few purplish spots on his lower extremities. He became weaker and had to go to bed at about that time. On April 21 the patient first reported to the hospital, at which time he was literally covered with purpuric spots and had several large areas of ecchymosis on his buttocks. The blood picture showed depression of all cellular elements, and a diagnosis of aplastic anemia was made. He was referred to a local sanatorium, and table 2 shows a summary of laboratory findings and treatment through his many admissions. A sternal bone marrow biopsy was studied by Dr. W. R. Mathews, who reported findings identical to those in case 1. The patient finally died on October 4, having lived about five months after discovery of his disease. His death was caused by shock precipitated by massive gastrointestinal hemorrhages.

CASE 3.—A white man aged 50 had been engaged in sweeping the floor in a cooling bay of a bomb loading line for about two months. He had been in excellent health. During a period of approximately forty-eight hours prior to reporting to the hospital he had noted that he did not feel quite as well as usual. About twenty-four hours before his appearance at the infirmary he noticed a number of small purplish spots on his lower extremities, and this was the thing that caused him to seek medical advice. When first seen the patient was well developed and well nourished and did not appear acutely ill. He treated his complaints lightly and was anxious to return to his day's work. He appeared more in search of information about himself than seeking treatment. Examination showed several petechiae on the upper extremities, with one or two large areas of subcutaneous hemorrhage in the right elbow region. The tourniquet test was positive. Blood studies revealed moderate depression of all cellular elements of the blood, with the platelet count being definitely reduced. In view of these findings a diagnosis of aplastic anemia seemed likely, and this was later proved by sternal bone marrow biopsy. Details of the study of the marrow were essentially no different than that seen in the first case. The usual therapeutic aids were given, including 3,100 cc. of fresh blood. His total red cell count reached 5,480,000, with 18.6 Gm. of hemoglobin, but his white cell count was never raised as high as 1,000 cells. Besides the fresh whole blood he was also given the cellular element from 2,500 cc. of blood. These cells were from the fresh blood prepared in the plasma bank at Shreveport Charity Hospital and were used within a few hours of preparation. The hospital course is summarized in table 3. His death followed a short episode of what undoubtedly was blood stream invasion.

Unfortunately, autopsies could not be secured in the last 2 cases.

COMMENT

The diagnosis of aplastic anemia in these 3 cases seems to be unquestionable. Case 3 shows a blood picture that may be confused with agranulocytosis, but the presence of purpuric phenomena, a low platelet count and a typical bone marrow picture substantiates the diagnosis of aplastic anemia. It may be well to stress the value of bone marrow biopsy with preparation of stained sections as a diagnostic aid in cases of this type. The incrimination of trinitrotoluene absorption as a cause of the pathologic process may be open to question particularly in the first case, in which 100 grains of sulfanilamide and cold capsules were given prior to a definite picture of aplastic anemia. On the other hand, who can deny that his original symptoms were not those of aplastic anemia? In this particular case I was unwilling to attribute the death to trinitrotoluene, but when 2 more cases developed in the same plant it was

felt that a change of outlook was in order. In these cases an investigation of previous employment, use of drugs, recent infections and other possible chemical or x-ray exposure was carefully made. In no case other than that noted was anything detected that appeared to be of importance. That any or all of these cases may be the so-called primary form cannot be denied; but the occurrence of these 3 cases fairly close together would seem to be asking a great deal of coincidence. These men were investigated from the standpoint of adherence of rules regarding change of clothes, bathing and other suggested precautionary measures. Only the first case showed anything of note and that was a failure to take the prescribed daily shower at the end of work. Bathing rules had not been strictly enforced among shipping room workers because it was felt that contamination was negligible.

Periodic examinations had been made on all of these men but had failed to give any warning of the impending disaster. The periodic examination is done by a nurse every three weeks, the findings being then studied by the medical staff. The examination consists, at this plant, of a general inspection with particular attention being paid to the condition of the skin and the color of the mucous membranes. The history regarding appetite, nausea and vomiting, abdominal pain and the sense of well-being is elicited. Following this, a record is made of the pulse, blood pressure and weight. The laboratory examination consists only of a hemoglobin determination. The entire procedure is intended only as a screening process, and suggestive findings call for more thorough investigation or a change in work for the employee. In case 3 the examination revealed nothing of note, with a hemoglobin of 13.5 Gm. only three days prior to hospitalization. That such is possible needs only a glance at the tables for confirmation, as they show a remarkably rapid course.

Test of air contamination in places where these men worked show no demonstrable trinitrotoluene in the shipping room where the first patient worked. The conditions in the cooling or puddling room were not as good, showing trinitrotoluene concentrations of from 1 to 3.5 mg. per cubic meter of air. While some of the samples are higher than the accepted maximum allowable concentration of 1.5 mg. per cubic meter, this is not an environment of considerable contamination as compared to a few other work rooms on a bomb loading line.

Medical Progress in Alexandria.—After the death of Erasistratus (300-225 B. C.) there was a lull in medical progress in Alexandria for almost five hundred years. The Greek medical center where the doctrines of Hippocrates and Aristotle were taught became a babel of medical concepts. Personal ambition, jealousy and greed divided the medical profession into many sects, systems and methods of teaching, each of which bore a distinct name. Those that received their main inspiration from the "Father of Medicine" were known as Dogmatists, albeit his methods of scientific investigation were not followed. Those who rejected medical authority and discarded the study of anatomy and physiology came to be known as Empirics. They depended entirely on experience (mainly of their own) as the basis of their therapy of the sick. Their principle was "post hoc, ergo propter hoc," a doctrine which still acts as an incubus in modern therapeutics and a handicap to scientific investigations.—Gordon, Benjamin Lee: *The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

THE EFFECT OF SODIUM BICARBONATE ON THE SERUM SALICYLATE LEVEL

DURING SALICYLATE THERAPY OF PATIENTS
WITH ACUTE RHEUMATIC FEVER

KATHARINE SMULL, M.D.

RENÉ WÉGRIA, M.D.

AND

JESSICA LELAND, Ph.D.

NEW YORK

During a study of massive salicylate therapy in rheumatic fever, a patient who was taking a constant daily amount of sodium salicylate by mouth and was maintaining a fairly constant serum salicylate level asked for sodium bicarbonate to relieve his "gastric discomfort." When this was given it was noted that the serum salicylate level fell decidedly, although the patient continued to receive the same dose of sodium salicylate.

Since it is claimed that plasma salicylate levels of at least 350 micrograms per cubic centimeter are impor-

the total daily dose was given every four hours day and night. After the serum salicylate level had become fairly stabilized, equal doses of sodium bicarbonate were given orally with each dose of sodium salicylate. Sodium bicarbonate was given for a variable period of time; it was then withdrawn and the patient was maintained for a further period on salicylate alone.

Two other healthy adults were given equal doses of sodium salicylate and sodium bicarbonate from the beginning of the experiment. After five days, sodium bicarbonate was withdrawn and the subjects were maintained for a further period on salicylate alone.

RESULTS

In chart 3 are shown observations made on a patient with acute rheumatic fever. The serum salicylate level during the first twelve days varied between extreme values of 381 micrograms and 558 micrograms per cubic centimeter of serum. Administration of sodium bicarbonate was then begun. Twenty-four hours after the initial dose, the serum salicylate level had fallen from 558 to 416 micrograms per cubic centimeter and, after another twenty-four hours, to 226 micrograms per cubic centimeter. On the third, fourth and fifth days

tant in the treatment of rheumatic fever¹ and since it is customary to give equal amounts of sodium salicylate and bicarbonate during salicylate therapy, it was thought of importance to investigate the influence of sodium bicarbonate on the serum salicylate level.

METHOD

Daily determinations of blood salicylate levels were made according to the method recently described by Brodie, Udenfriend and Coburn,² with the one modification that the determinations were made on serum instead of plasma.³ In order to minimize the irritant effects of the drug on the gastrointestinal tract, enteric coated tablets of sodium salicylate were used exclusively throughout the work.

Four adult patients with acute rheumatic fever and 2 healthy adults were given sodium salicylate by mouth in doses ranging from 7.2 to 10 Gm. a day. The dose for each individual was kept uniform, and one sixth of

the salicylate levels were respectively 209, 169 and 189 micrograms per cubic centimeter. After the administration of sodium bicarbonate was discontinued, the serum salicylate level rose rapidly, and one, two, three, four, five and six days after the sodium bicarbonate was discontinued the salicylate levels were 270, 406, 461, 486, 465 and 506 micrograms per cubic centimeter of serum respectively. Equally striking effects were obtained in 3 other rheumatic patients.

The results obtained in a healthy woman are shown in chart 1. Comparable effects were observed in a healthy man. The findings are essentially similar to those seen in the cases of rheumatic fever. The control periods, i. e. the periods during which sodium salicylate alone was given, are not as long as those observed in the cases of rheumatic fever because they were thought to be unnecessary. It should be noted, therefore, that the serum salicylate level had not yet reached a plateau and was still increasing when the administration of sodium bicarbonate was begun.

These observations show clearly that a serum salicylate level which has been established and is being maintained by the oral administration of sodium salicylate is definitely lowered when approximately equal amounts of sodium bicarbonate are given simultaneously.

It was then thought to be of interest to investigate, in another type of experiment, what serum salicylate level can be established when equal doses of sodium

3. A few determinations of salicylate levels on plasma and serum obtained from the same sample of blood showed that the serum levels are slightly higher than the plasma levels. This difference, obtains whether the determination is done immediately after the blood has been drawn or after the blood has been allowed to stand as long as thirty-six hours at room temperature.

bicarbonate and salicylate are given simultaneously from the beginning of the experiment. The results obtained in a healthy man are shown in chart 2. In this experiment the serum salicylate level varied between 267 and 319 micrograms per cubic centimeter. When sodium

The results obtained in all the experiments are summarized in the accompanying table.

COMMENT

Recent studies by Coburn¹ suggest that the maintenance of a high salicylate level in the blood is important for the effective treatment of acute rheumatic fever. He has demonstrated that, whereas levels below 200 micrograms per cubic centimeter of plasma are sufficient to relieve the symptoms, it seems probable that a concentration of at least 350 micrograms may be required to suppress the "rheumatic reaction." Our observations show that sodium bicarbonate, in the amounts customarily given together with sodium salicylate, definitely depresses the blood salicylate level. The implication of this finding with respect to adequate salicylate therapy is obvious.

It was considered possible that a high concentration of sodium bicarbonate in the blood might invalidate the method of determining the serum salicylate level. The

Chart 1.—Effect of sodium bicarbonate on the serum salicylate level of a healthy woman.

bicarbonate was withdrawn, the salicylate level rose to 427 micrograms per cubic centimeter within twenty-four hours and 484 micrograms per cubic centimeter within forty-eight hours. It is thus apparent that the

Chart 2.—Effect of sodium bicarbonate on the serum salicylate level of a healthy man.

simultaneous administration of equal doses of sodium bicarbonate and salicylate prevents the establishment of as high a salicylate level as is obtained when salicylate alone is given. The effect was similar with another healthy subject.

Chart 3.—Effect of sodium bicarbonate on the serum salicylate level of a man with acute rheumatic fever.

salicylate level was determined on samples of several serums. The determinations repeated after sodium bicarbonate had been added in the serums (2 mg. of sodium bicarbonate per cubic centimeter of serum) yielded identical results.

A priori, it would seem that the fall in the serum salicylate level caused by sodium bicarbonate could be due to one of a number of factors or to several acting together: (1) Sodium bicarbonate interferes with the absorption of sodium salicylate in the intestine; (2) sodium bicarbonate causes an increase of extracellular fluid which leads to a decrease in the titer of sodium salicylate in the blood; (3) sodium bicarbonate increases the renal excretion of sodium salicylate or its derivatives. At the present time it is not possible to say which of these may be responsible for the observed fact.

CONCLUSIONS

1. When a serum salicylate level has been established and is being maintained by the oral administration of enteric coated tablets of sodium salicylate, the simul-

taneous administration of approximately equal amounts of sodium bicarbonate results in a definite fall of the serum salicylate level.

2. The simultaneous administration of equal amounts of sodium bicarbonate and enteric coated sodium salicylate prevents the establishment of as high a serum salicylate level as would be obtained with sodium salicylate alone.

TREATMENT OF RECURRING ATTACKS OF LOW BACKACHE WITH- OUT SCIATICA

WALTER E. DANDY, M.D.
BALTIMORE

Recurring attacks of low lumbar backache, plus sciatica in the back of the leg, are almost pathognomonic of defective intervertebral disks. With few exceptions the backache and sciatica are intensified by coughing and sneezing during the periods of acute pain. A frequent story given by these patients is that for some weeks, months or years there are only recurring attacks of backache, i. e. without the sciatica, and that at a later date the sciatica is superimposed. Such histories suggest that with the recurrent backaches alone one is dealing with precisely the same underlying lesion as when the sciatica is added. This report of 20 cases is from this group, none of whom have ever had sciatica. Moreover, there is no greater uncertainty in the diagnosis of the lesion without, than with, sciatica; nor is there any greater difficulty in localizing the affected disk or disks. It is by no means to be inferred that all patients with recurring attacks of backache or backache with sciatica are advised to be operated on. There are many who can go along in comparative comfort by avoiding strains to the back. Operation is indicated when the backaches are frequent and severe. However, since the operation is without risk and the results are now excellent and permanent, there is no reason for patients to suffer, particularly since spontaneous cure is uncommon and requires many years.

DIAGNOSIS OF DEFECTIVE DISKS

From signs and symptoms alone, defective disks causing backache with or without sciatica can be diagnosed in approximately 95 per cent of all cases; with symptoms plus x-ray examination of the lumbar spine, in over 98 per cent. X-ray examinations serve to differentiate spondylolisthesis and congenitally defective vertebrae, both of which produce symptoms that are quite similar.

From x-ray examinations of the lumbar spine alone the diagnosis can be made in over half the cases. Narrowing of the intervertebral space is pathognomonic objective evidence of a defective disk. Not infrequently two disks are narrowed in the roentgenogram and occasionally all the lower three; at times, other disks are similarly affected. When multiple, they may or may not be affected in sequence. In 12 of the 20 cases in this series of disks without sciatica, this roentgenographic evidence was present.

Until recently, defective disks were diagnosed only by injections of iodized poppyseed oil, air or other contrast mediums into the spinal cord. In recent communications I have shown that these are never necessary and are always inadvisable, for the following reasons: 1. They diagnose and localize disks in only

about one fourth of the cases because only the large disks produce a filling defect in the contrast medium. 2. They frequently give equivocal results and therefore unreliable information. 3. They are painful, and if a solid contrast material is used and removed (as it should be) it is a long and harrowing ordeal to the patient. 4. There are occasional temporary and even permanent after-effects from the injected material.

Since, seemingly paradoxically, defective disks can be diagnosed and localized in over half the cases by simple x-ray films and in only one fourth of the cases by spinograms, and since all disks can be diagnosed by the history and neurologic examination and x-rays without contrast mediums, there is no possible reason for using spinal injections in any form. They just don't make sense.

Spinal tumors (now about 1 per cent) give the only real difficulty in differential diagnosis. The signs and symptoms of tumors may be identical with those of a disk, but one can frequently suspect a tumor by some progressive sensory or motor change (these also occur with disks) or by loss or diminution of a patellar reflex (this also occurs with disks). I have missed 9 tumors of the cauda equina among 1,100 disks; 8 of these I found later; the ninth was removed by another surgeon. On the other hand, I have diagnosed and removed 5 additional tumors among patients whose symptoms were somewhat similar to those of disks. Five more cases of metastatic tumors in the spine have been left untreated; usually the pain in metastatic lesions is continuous and not recurring. If a tumor is suspected, a lumbar puncture should be performed (this is the only occasion for tapping the spine). Xanthochromic fluid will usually indicate a tumor, and its absence a disk. A Queckenstedt test should be made at the same time in order to determine a partial or complete block in the spinal canal. These tests are not absolute (they were lacking in 1 case) but are nearly so.

Twenty patients having backache without sciatica have been operated on during the past three years. The history is much the same in all cases, i. e. recurring attacks of low backache and nothing more. Usually, but not always, the pain is intensified by coughing and sneezing. Each attack lasts one to three weeks, after which the patient is relatively free from pain until a new attack is precipitated by a strain such as a heavy lift, a twist of the back, a fall or any sudden movement. There may, however, be no definite precipitating cause. Sixteen patients were males, and 4 were females.

A total of 32 disks have been removed from the 20 patients; of these, 7 were large, protruding and nerve compressing, although there had never been sciatica. Twenty-five of the 32 disks were of the so-called concealed variety, i. e. too small to have been diagnosed by contrast mediums had any been used. In 6, or nearly one third, of these cases, the recurring backaches dated back more than ten years, i. e. ten, thirteen, fourteen, eighteen, twenty-five and thirty years; the shortest duration of attacks was two years.

When this study was begun I had been removing the entire disks but not so thoroughly as at the present time. However, I did not know that disks were so frequently multiple (80 per cent). Fair judgment on results of disk treatment can therefore be made only after this new information has been utilized. This date has been set at June 1, 1943, one year ago. Ten patients in this series were operated on before and 10 after this date. Of the 10 cases before June 1, 1943, single disks were

removed in all; in 2 cases a second disk was subsequently removed when symptoms continued, and, in 2 more, additional disks are believed to be present because of continued backache. Of the 10 cases in which operation has been performed since June 1, 1943, none have required reoperation. One patient has some backache but not severe enough for another operation, and a second has severe pain but has lost confidence and will not return for examination or operation. It is my belief that both these patients have a third disk. Recurrence of the disk is possible but unlikely. The remaining 8 cases are free from backache. This period of one year is much too short to warrant any conclusions concerning the permanence of results; but in over 800 cases of disks (with sciatica) removed completely in the past two years there have been only 2 known recurrences at the operated disks (both over a year ago) and 3 instances in which

Bony union between fourth and fifth vertebrae four years after partial extirpation of the disk.

sciatica has returned on the opposite side (but at the site of the previously removed disk). Return of pain on the opposite side must always be a possibility—because it is difficult or perhaps even impossible to elevate the spinal dura sufficiently to remove the cartilage in this corner of the disk completely. This could be avoided by opening the contralateral side, but with such a low percentage of trouble from this source I prefer, for the present at least, to accept this liability rather than increase the magnitude of the operation.

The preceding statement of results means actual recurrence of a disk demonstrated at operation. It does not mean recurrence of pain for which another disk has been found to be responsible. There have been perhaps a dozen of these. Nor does this statement imply that a higher percentage of recurrences will not appear subsequently. But considering the high percentage of actual recurrences that obtained when disks were only partially removed, no doubt can remain of the much improved results after their complete removal.

Sufficient time has not elapsed to justify a dogmatic statement that complete removal of disks will result in a permanent cure; but if the operation is properly done, I do not see how a permanent cure can fail. This is therefore not a statement of fact but an impression from experiences up to the present time. To remove a disk completely or essentially completely is a tedious and time consuming procedure (about an hour for 2 disks). Doubtless even the most careful operator will have recurrences because of an incomplete attack on the disk, but the recurrences should be few; and in the last analysis it will be the surgeon's mistake and not the mistake of the method. To speak of complete removal of disks is not strictly accurate; an absolute removal of all cartilage is impossible, but the small amount that remains on the fringes of the vertebrae gives no trouble. The removal is essentially complete.

An important view of defective disks is this: Should symptoms recur, either in exactly the same or a different form after three or four months, the explanation can be found and corrected. There are three possible causes of continuing trouble: (1) a recurrence of the original disk, (2) another disk which was missed at operation or (3) a tumor of the spinal cord or cauda equina (about 1 per cent). At operation it is possible by the mobility test to tell which of the first and second items is the cause and to correct it.

Much stress has been placed on a psychogenic factor or malingering in case of continuing pains before and after operation. These are always possible factors both in the preoperative diagnosis and in the post-operative failure to cure. However, there should be little difficulty in interpreting these elements either before or after operation. A psychoneurotic backache is nearly always continuous and therefore does not have the remissions that are so characteristic of defective disks. And patients of this type will not volunteer that coughing and sneezing accentuate the backache or sciatica. Finally, and most important, the psychoneurotic element is evidenced by spreading of the pain up the back and to the arm and even to the head. Such extensions can have no organic explanation. As a matter of fact, I have found psychoneuroses to be uncommon factors; and, when present they are easily differentiated from the real. With few exceptions the patient is right when symptoms continue and the doctor's explanation of a functional background is wrong.

When a disk is defective, whether concealed or protruding, the joint is more movable than normal, and by pushing the spinous processes caudally with an instrument the affected disk or disks can be identified by this increased mobility. The only failure of this test occurs when there is a narrowing of the intervertebral space in the x-ray film; the joint may then be immobile or nearly so. This test is as effective in localizing the disks causing a backache without sciatica. In a single case in this group the disk was at the second lumbar vertebra, but local tenderness and x-ray findings indicated its higher location.

TYPE OF OPERATIVE TREATMENT

The treatment of defective disks is precisely the same for backache alone as for backache plus sciatica. The mere removal of the protruding portion of a disk is unsatisfactory in the long run because a high percentage—at least a third and, with additional time, probably more—will recur from the cartilage that remains, and

with concealed disks the protrusion is too small to be removed. The present operative attack on disks is to remove them as completely as possible with curets, baring the bone. The joint then narrows, and the cavity fills with connective tissue. This procedure does what nature attempts to do slowly over many years, as is evidenced by the narrowing in the x-ray appearance. Three months after complete excision of the disk the joint, when exposed at operation, is absolutely firm; this has been demonstrated repeatedly. It is believed that bony union will eventually ensue, but I have only a single case to warrant this supposition. Recently a patient was shown to have bony union after four years, as may be seen in the illustration, although at that time the disk was only partly removed. The complete removal of the disk causes no more immediate or late after-effects than the partial removal. There has as yet been no instance in which a joint has been known to become loose after healing. There is reason to believe that the permanent fixation of an excavated disk should be maintained precisely as after trauma causing fractures of the spine involving the disks.

THE CAUSE OF DEFECTIVE DISKS

The underlying cause of defective disks is an inherent weakness in the lower lumbar spine. A superimposed factor is trauma—such as a heavy lift or twist or bend of the back or a severe cough or sneeze—which may or may not be severe enough to be appreciated at the time. Specifically, the weakness of the spine is due to a shift in the direction of the planes of the lateral articulations between the last three lumbar vertebrae and the sacrum, particularly between the fourth and fifth vertebrae and the sacrum. At the first two lumbar vertebrae the lateral joints parallel the spinous processes; at the third lumbar the plane of the joint turns laterally 15 to 25 degrees; at the fourth it turns out 25 to 45 degrees, and at the junction between the fifth and the sacrum the joint may be everted as much as 90 degrees from the spinous processes. At four, and particularly at five, the joint may also be turned upward and face in varying degrees a craniocaudal direction. Many disks are flat or nearly so, instead of vertical, and this leads to the frequency of spondylolisthesis, especially at the lumbosacral angle. There are varying degrees of these changes in the joints and much asymmetry in the two sides. The purpose of the shifting articulations is doubtless to provide movement—flexion, extension and rotation in the back. At the same time they create definite weakness of the spine and allow any undue trauma, even very slight, to loosen the joint or joints; this weakness then transfers increasing trauma to the corresponding disk or disks. This structural variation also accounts for the high frequency of multiple disks.

CONCERNING CONCEALED DISKS

There can never be any disagreement concerning protruding disks. Surgeons have been reluctant to accept the so-called concealed disks, i. e. small disks that do not elevate the nerve, which I believe to be just as easily diagnosed and localized and treated as the large ones; and they are three fourths of the total number. Just as one can diagnose a small tumor of the breast as unequivocally as a large one, so the diagnosis of a small disk is just as definite as a large one. There is nearly always some actual protrusion; it fluctuates when pressed on by forceps; the overlying ligament is much more opaque than the normal; it is adherent to

the surrounding structures, and when opened the forceps dip without resistance into a cavity and frequently sequestrums of varying size can be extracted. The location of the disk, whether small or large, is disclosed by the excess movement of the joint (the mobility test), except as previously noted, when the x-rays disclose a narrowing of the intervertebral space. The small concealed disks give precisely the same symptoms as the large ones, the only difference being the intensity and persistence of the symptoms—backache with or without sciatica. When sciatica is persistent and intense the disk will always be large and protruding, but a large disk may be present without intense symptoms, as in some of the cases here reported. By the symptoms one can usually predict the size of the disk. The treatment of small disks is precisely the same as of the large ones and is just as effective. Those who doubt concealed disks can never doubt the demonstrable increased mobility at the joint, which is the real source of symptoms; a loose joint must cause symptoms.

THE CAUSE OF BACKACHE AND SCIATICA

The cause of backache and sciatica cannot be stated with certainty. From a study of cases before and after operation, I now believe that the lateral joints and the corresponding disks are all participants and that probably the initial pain is from movement of the lateral facets and that the disk is secondarily and necessarily affected. The anatomic variation of the lower lumbar lateral facets, which is surely the cause of defective disks, suggests this. If the lateral facets are loose, the disk itself, which bears most of the weight of the spinal column, will participate in the increased mobility; thus all three joints are affected. Since at times the backache is unilateral, the lateral facet of one side is probably responsible for the backache; the mobile disk could hardly produce unilateral backache. A more obvious reason for believing that the loose facets cause the backache and sciatica as well is the postoperative story of an occasional patient after complete removal of the disk. In 3 patients an attack of severe backache and sciatica was precipitated immediately after they had got out of bed seven to ten days after operation. The attacks were identical with those before operation, but after the subsidence of symptoms a week or two later there was never a return of the symptoms. It can hardly be doubted that the lateral facets had slipped with the sudden application of weight, there being no disk to modify the strain. Certainly, the complete absence of the disk would eliminate protrusion of the disk as the factor in the sciatica. Therefore the sciatica, at least, must be referable to the lateral facets and probably was due to the swelling about these joints or possibly even to the actual slipping of the joint against the nerve.

Another reason for this explanation of the sciatica and backache is that in spondylolisthesis, in which the symptoms are identical, defective disks, either protruding or concealed, are not always present. Therefore it must be assumed that an explanation other than a disk must obtain—probably the slipped facets.

If this explanation is correct, it can be applied to the causation of backache and sciatica in the presence of concealed disks. It is difficult to explain sciatica on the finding of small disks that do not protrude against the nerve. It might be assumed that the disk, which is small at operation and probably even more reduced in size by the ventral position of the patient, might protrude inter-

mittently, especially under the influence of trauma, and then compress the nerve. The fact that the disk is usually adherent to the nerve or the dura or both also suggests that there has been preexisting pressure on the nerve. This explanation may or may not be satisfactory, but proof is lacking. It was my original explanation of sciatica before realizing that the lateral joints could probably cause it. Unless or until a disk actually compresses the nerve, it is more reasonable to assume that the lateral facets are responsible for the sciatica. How much of the backache is due to the lateral facets and how much to the disk itself can only be conjectured; both may play a part. The problem of defective disks, therefore, is one not only of the disk but of all three joints between the vertebrae; but always the disk is defective.

WHY REMOVE DISKS COMPLETELY?

If the lateral facets are responsible for much, at least, of the backache and pain, one may well ask Why attack the disks instead of the facets? The first answer is that the disk is probably always affected; the second, that stabilization of the facets by operation is difficult or at the present time, at least, impossible; the third, that the removal of the disk stabilizes the vertebral column by an actual fusion of the vertebrae, after which the facets take care of themselves. The disks offer a broad surface for fusion; the lateral facets are curved and small. In several instances I have opened the lateral joints and to some degree denuded the cartilage, but the total area involved is small and offers only a fraction of the stabilization offered by removal of the disk; even as a supplementary procedure it is probably of no practical value because fusion after extirpation of the disk is extensive and adequate. From an experience with 30 cases of reexplored disks (for recurrence of pain and before disks were known to be multiple) it is now known that the union between the vertebrae is so firm three months after a disk has been completely removed that there is no movement at the joint. If there is movement at the joint after this time the disk had not been completely removed and is therefore recurrent. And it is also known from exposures after an interval of a year that the joint remains solid; and from absence of symptoms after two and a half years there is no reason to believe that the healed space has changed in this respect.

WHY ARE FUSIONS (BONE TRANSPLANTS) OF THE SPINE TO BE CONDEMNED?

Most neurosurgeons still fuse a varying percentage of the cases in which disks are removed. The reason for this is that their experience with the operative treatment of disks has been unsatisfactory. The reasons for unsatisfactory results have been stated, i. e. (1) failure to remove the disks completely, thus obviating recurrence, and (2) the failure to recognize multiple disks. The use of bone grafts to the spine is therefore a confession of poor results. A fusion operation will improve the situation but little, if any, because the recurrent disk or the additional disk is merely covered up. After complete removal of disks the fusion of the spinal column is more nearly perfect than the most successful bone graft can be, and at the same time the cause is removed. Fusion by bone grafts is a big procedure and necessitates a prolonged stay in the hospital in a cast; fusion by removing the disks means hospitalization for only a week to ten days. I have

reoperated on perhaps 15 patients who have had spinal grafts performed—all without relief of symptoms—and only 3 of the grafts persisted in position and afforded any stabilization of the spine; even these did not even modify the pain. It can be said unequivocally that in the treatment of ruptured disks a spinal fusion by bone grafts is never necessary and cannot be too strongly condemned.

Since removal of intervertebral disks appears to be a more rational method of stabilization of the spine, I have in the past year performed operations in 25 cases of spondylolisthesis of the lesser grades and 5 cases of congenitally defective vertebrae by extirpating the disk, instead of by spinal fusions.

CONCLUSIONS

1. Recurring attacks of low lumbar backache without sciatica have precisely the same underlying cause as backaches plus sciatica, i. e. defective intervertebral disks.

2. In one third of the 20 cases here reported there were large protruding disks compressing the nerve, despite the fact that sciatica had never been present.

3. The diagnosis of defective disks is made solely from the history, the neurologic examination (frequently negative) and x-ray examinations of the spine. The latter give pathognomonic evidence of defective disks in over 50 per cent of the cases.

4. The disks are localized at operation by the mobility test (movement of the affected joint).

5. Defective disks are multiple in 80 per cent of the cases, with or without sciatica.

6. All spinal injections for diagnosis or localization are unnecessary; they are painful, sometimes cause serious after-effects and at best make the diagnosis and localization in only 25 per cent of the cases, whereas over 98 per cent can be diagnosed and localized without them. Even simple x-ray films alone diagnose more than 50 per cent. Spinal injections of any type should be strongly condemned.

7. Recurrence of disks should be reduced to a minimum by their complete removal. This results in fusion between the affected vertebrae and obviates any necessity for fusion by spinal grafts: Fusions of the spine are never necessary! If backache or sciatica returns or persists there are three possible explanations: 1. A disk has been missed. 2. It has been incompletely removed. 3. There may be a tumor.

Johns Hopkins Hospital.

Dermatology in Early Modern Europe.—At the beginning of the seventeenth century came the discovery of the microscope, which opened up the universe of the infinitely little, as the telescope did the universe around us. During this period medicine kept the pace; it carried its studies as far as could be done without the instruments of precision of the nineteenth century. Anatomy, physiology, pathology and clinical medicine were investigated to the limit of the resources of existing scientific knowledge. Medicine had a particular reason for the stimulation of its activity in the sudden appearance of syphilis at the very beginning of this period. The study of skin diseases was more than ever a subject of major interest in medicine, because of the cutaneous manifestations of syphilis, which emphasized the importance of skin diseases. The history of dermatology during the period is that of rapid increase in knowledge through the investigations of men, many of whom are the great figures in early modern medicine.—Pusey, William Allen: *The History of Dermatology*, Springfield, Ill., Charles C Thomas, 1933.

LACTIC ACID: A CORROSIVE POISON

REPORT OF THREE FATAL CASES WITH
EXPERIMENTAL CONFIRMATIONE. GORDON YOUNG, Ph.D., F.R.S.C.
ANDRALPH P. SMITH, M.D., D.P.H.
HALIFAX, N. S.

The common occurrence and physiologic role of lactic acid have tended to establish the general opinion that this substance is not to be considered as poisonous. Lactic acid is not mentioned in any of the standard textbooks on toxicology. We have been able to find only one reference to it as a cause of death in a human being. Leschke¹ cites a case described by Fühner² of a woman aged 27 who died in twelve hours after the administration by duodenal tube of 100 cc. of a 33 per cent aqueous solution of lactic acid in error for magnesium sulfate. This resulted in dyspnea, vomiting of blood and mucus, a rapid feeble pulse, hemoglobinuria and cyanosis. The autopsy revealed a dark red patch of erosion in the duodenum. Both duodenum and jejunum showed hemorrhagic infiltration of all coats and necrosing inflammation. Leschke remarks that "lactic acid has a corrosive action exactly like that of any other acid of corresponding hydrogen ion concentration." The dissociation constant of lactic acid (K_a) is usually given as 1.38×10^{-4} at 25 C.³ This makes it comparable with formic acid at 2.14×10^{-4} , long considered a poisonous corrosive and almost ten times stronger than acetic acid, which has also been so classified when in high concentration.

From the experimental point of view there is confirmatory evidence. Dreyfus⁴ has shown that the rectal administration of 40 cc. of a 3 per cent solution of acetic, butyric, lactic or tartaric acids to rabbits caused death in a few hours. Pike, Osnato and Notkin⁵ injected lactic acid in doses of 0.07 to 0.1 Gm. per pound of body weight into cats to produce convulsions, which were later followed by death with respiratory failure and pneumatorrhaxia. Lastly, Fürth and Engel⁶ found that lactic acid given orally to rabbits in doses of 0.6 to 1.6 Gm. per kilogram of body weight caused death, and they quote Parnas as showing that 2.8 to 3.6 Gm. per kilogram could be given intravenously. They state that mice can withstand about the same dosage as rabbits but that rats are more resistant. In rats and mice alkalosis induced by sodium bicarbonate did not alter the effect.

Recently we were called on to investigate the cause of death of 3 premature infants. They were all being fed the same lactic acid milk mixture on the basis of

the following formulas, and all ingredients had been used previously for the same purpose: (1) evaporated milk, water and acid sugar solution, equal parts; (2) acid sugar solution: water, 1 pint, corn syrup, 1 tablespoon, lactic acid (concentrated) 1 teaspoon.

REPORT OF CASES

CASE 1.—Clinical History.—Baby H., a very small white girl aged 35 days, weighing 3.85 pounds (1,746 Gm.), was found dying three quarters of an hour after receiving the lactic acid milk mixture by gavage. She was one month premature and weighed 3.38 pounds (1,533 Gm.) at birth.

Autopsy Findings.—The autopsy was performed within a few hours of death.

General Appearance: There were no excoriations on the face, mouth or lips.

Lungs: The right upper lobe showed minute peribronchial hemorrhages with pus exuding from the bronchioles. Microscopic examination revealed this to be a typical capillary bronchitis. Areas of emphysema, atelectasis and acute congestion were also present in the lung. The left lung showed only a little acute congestion.

Esophagus: There was a small black necrotic, eroded area at the cardiac end, extending into the stomach, which was confirmed histologically.

Heart: The heart was normal except for some cloudy swelling of the myocardium and a little terminal dilatation of the right side.

Peritoneal Sac: The peritoneal sac contained some blackish fluid stomach contents.

Stomach: This had perforated, and its blackish, mucous contents had exuded. Its wall was black, hemorrhagic, necrotic and extremely friable and the seat of an acute gangrenous gastritis.

Intestine: Except for a slight injection of the jejunum, the intestine showed no gross or microscopic change. The contents were not blood stained.

Mesentery and Omentum: These showed white necrotic areas on a black gangrenous background.

Pancreas: Gross examination revealed some blackening and superficial necrosis externally, but only some congestion was visible on microscopic examination.

Liver: There were areas of superficial hemorrhage and acute congestion with cloudy swelling of the liver cells, confirmed histologically. The under aspect of the left lobe was blackened from the action of sulfide.

Spleen: It was very soft, toxic and congested.

Adrenals: Except for some superficial discoloration of the left gland, they were normal.

Kidneys: The kidneys showed cloudy swelling and some congestion of the glomeruli but no nephritis.

Comment: The capillary bronchitis present in the right lung would appear to have been present before the poisoning in view of the short time which elapsed between the feeding with the lactic acid milk mixture and death.

Pathologic Diagnosis: Acute gangrenous gastritis, a result of corrosive poisoning; capillary bronchitis of the right lung; toxemia.

CASE 2.—Clinical History.—Baby C., a small white girl aged 37 days and weighing 4.33 pounds (1,965 Gm.), was found in a collapsed, pale, distressed condition with a feeble rapid pulse. She died three and one-fourth hours after receiving the lactic acid milk mixture by gavage. Although two months premature, she was otherwise healthy and weighed 3.63 pounds (1,581 Gm.) at birth. Oxygen and carbon dioxide were given without avail.

Autopsy Findings.—The postmortem examination was performed within four hours of death.

General Appearance: No excoriations were visible on the face, lips or mouth.

From the Departments of Biochemistry and Pathology, Dalhousie University.

Dr. F. V. Woodbury, medical coroner, referred the cases to us. Mr. F. A. H. Rice assisted with some of the experiments. Dr. G. B. Wiswell supplied the clinical data.

5. Pike, F. H.; Osnato, M., and Notkin, J.: *The Combined Action of Some Convulsant Agents in Small Doses and the Action of Bromides in Experimentally Induced Convulsions*, *Arch. Neurol. & Psychiat.* 25: 1306-1314 (June) 1931.

6. Fürth, O., and Engel, P.: *Ueber die Assimilierbarkeit und Toxizität racemischer Milchsäure*, *Biochem. Ztschr.* 229: 381-396, 1930.

Lungs: Both lungs showed acute congestion and there were some petechiae in the upper lobes. No evidence of pneumonic change, either gross or microscopic, was detected.

Heart: Except for one small petechial hemorrhage on its surface near the base of the left ventricle and some cloudy swelling in the myocardium, the heart was otherwise normal.

Peritoneal Sac: It contained some blackish stomach contents.

Esophagus and Stomach: There was a black gangrenous area in the esophagus $\frac{1}{2}$ inch from the cardiac end of the stomach. The whole wall of the stomach was black and extremely friable and exhibited an intensely acute gangrenous gastritis with a small area of early erosion and perforation.

Intestine: The duodenum, jejunum and ileum all showed an acute enteritis, but the large bowel was relatively free, with nothing abnormal in the sigmoid or rectum.

Mesentery of the Small Intestine and Omentum: White necrotic areas were visible on a black gangrenous background.

Mesenteric Lymph Nodes: They were somewhat enlarged from a simple acute lymphadenitis.

Liver: The liver showed pronounced cloudy swelling and acute congestion.

Spleen: It was very soft, congested and toxic.

Kidneys: Both kidneys were the seat of cloudy swelling and acute congestion, and some petechial hemorrhages were seen at the upper pole of the left. No nephritis was present.

Pathologic Diagnosis: Acute gangrenous gastritis with perforation and acute enterocolitis, suggestive of corrosive poisoning; toxemia.

CASE 3.—Clinical History.—Baby M., a small white boy aged 17 days and weighing 4.16 pounds (1,887 Gm.), was under observation for a longer time than the 2 previous infants as fifteen and one-half hours had elapsed between the feeding of the lactic acid milk mixture by gavage and death. The baby was born at seven and one-half months of term and was thus six weeks premature. The birth weight was 3.81 pounds (1,728 Gm.).

The main symptoms were those of pallor, collapse and a feeble, rapid pulse. There were no convulsions or vomiting, and no staining of the diapers was noted, such as would have been expected with a hemoglobinuria. Up to the time of the onset of the symptoms of poisoning the infant was healthy and progressing favorably. Nikethamide and vitamin K were given without result.

Autopsy Findings.—The autopsy was performed two hours after death.

General Appearances: There were no excoriations of the face, lips or mouth.

Lungs: The lungs showed only acute congestion and some petechial hemorrhages. No signs of capillary bronchitis or of pneumonia were present.

Heart: The myocardium showed cloudy swelling, but there was no other abnormal change seen.

Esophagus: The last 2 inches of its lower end were necrotic and gangrenous.

Stomach: As in the previous cases, the wall was blackened and hemorrhagic and was the seat of an acute hemorrhagic and gangrenous gastritis. No perforation, however, had occurred. The contents had a black color.

Intestine: Both the small and the large intestine were inflamed and the seat of an acute enterocolitis which extended down to the sigmoid colon.

Mesenteric Glands: They were enlarged and showed an acute lymphadenitis.

Liver: There was a pronounced cloudy swelling, fatty degeneration and acute congestion with small scattered areas of hemorrhage. Although a slight increase in the cells in the portal tract areas was visible, no true toxic necrosis could be identified on microscopic examination.

Spleen: It was slightly enlarged, soft, toxic and intensely congested, with hemorrhagic areas through the pulp.

Kidneys: Both showed considerable cloudy swelling with some necrosis of the secreting tubules, diffuse congestion of the blood vessels and some generalized swelling of the glomeruli, with congestion of their capillaries. The condition present had the character of an acute catarrhal nephritis or nephrosis. No accumulations of hemoglobin were visible in the collecting tubules.

Urinary Bladder: This was normal and contained practically no urine.

Pathologic Diagnosis: Acute gangrenous gastritis and acute enterocolitis with acute nephrosis or catarrhal nephritis, a result of corrosive poisoning; toxemia.

CASE 4.—The same lactic acid milk mixture was also given by bottle to a 10 day old full term infant, but after one mouthful, which caused choking and reddening of the face, the baby spit it out and refused to take more.

Dr. Wiswell informs us that the baby developed an infected throat and suffered from a little bronchial irritation with wheezing for a day or two but made a complete recovery. Refusal to take the mixture evidently was the means of saving its life.

CHEMICAL EXAMINATION

Unfortunately, the acid milk mixture fed to the babies was thrown away immediately after the first death was discovered and was therefore not available for analysis. Furthermore, the amount of the mixture taken by the babies was not exactly known, but it was probably about 1 ounce. The various ingredients were, however, examined qualitatively and the hydrogen ion concentration determined either colorimetrically or electrometrically by a Beckman p_H meter. All conformed to their labeled contents. The corn syrup was acid, with p_H at 4.63, and the evaporated milk at p_H 6.7. The lactic acid possessed a specific gravity of 1.2, corresponding to the U. S. P. syrupy variety at 85 per cent with a p_H less than 1.

The stomach contents, together with peritoneal fluid, from case 1 measured 25 cc. of a dark brown mucous liquid without curds and with a slightly sour odor. The p_H was 2.5. The p_H of the stomach contents in case 2 was 3.0 and in case 3 about 5. A determination of the content of lactic acid in the stomach contents in case 1 was carried out according to the technic of clarification of Gerty T. Cori⁷ and of estimation of Friedmann and Kendall⁸ with the apparatus of West.⁹ The concentration was 0.19 per cent lactic acid, or a total of 41 mg. in the whole specimen.

EXPERIMENTS WITH RABBITS

The experimental feeding of the milk mixture with an increased amount of lactic acid was next tried on adult rabbits. The formula used was made up of equal parts of the original evaporated milk, water and the concentrated lactic acid (85 per cent). This mixture was rather disagreeably acid to taste and had a p_H of 2.1. It was 34 per cent (w/v) lactic acid. The casein curd which formed initially dissolved as the hydrogen ion concentration passed to the acid side of the iso-electric point.

RABBIT 1.—One ounce, i. e. approximately the amount of the feeding estimated by the nurse, of this mixture was given by stomach tube to a 6 pound rabbit which had not been fed for about twelve hours. The animal was soon obviously distressed,

and the respiration became labored at 64 per minute in one hour. The rabbit died suddenly in convulsions within two hours. There was no vomiting, defecation or urination throughout the period. This would indicate death following a dose of 10.2 Gm., or about 1.7 Gm. per kilogram, i. e. 0.77 Gm. per pound for this rabbit. This dosage is of the same order of magnitude as the minimum lethal dose recorded by Furth and Engel⁶ at 0.6 to 1.6 Gm. per kilogram. At autopsy the stomach was found greatly distended with fluid containing mucus, blood and much fecal material. The fundic portion of the wall was very thin and near to perforation. The mucosa showed an intense, hemorrhagic, almost gangrenous, acute gastritis. The duodenum was soft and congested, and the rest of the small intestine was essentially empty. The jejunum showed some hemorrhages into its mucosa in the upper portion. The spleen was congested, rather soft and toxic, with some hemorrhages into the pulp. The kidney showed only some congestion and cloudy swelling. The lungs were edematous, congested and hemorrhagic but showed no evidence of capillary bronchitis or bronchopneumonia. The urine was scanty (2.5 cc.), very turbid with amorphous phosphates and distinctly alkaline (pH 8.8). There was no protein or sugar present. The pathologic diagnosis of cause of death was acute hemorrhagic gastroenteritis. This is a striking confirmation of the suspected cause of death of the 3 babies, as the clinical and pathologic pictures were so similar.

RABBIT 2.—Another animal, weighing 5 pounds, was fed by stomach tube 30 cc. of a mixture of 2 parts whole milk to 1 part lactic acid (U. S. P. 85 per cent). This solution had a pH of 1.58. The rabbit had been starved for sixteen hours previously. It was our purpose to study the effect on the alkali reserve of the blood in this animal and to determine the rate of absorption of the lactic acid. The respiratory rate was very rapid throughout most of the period, beginning at 150 per minute, rising to 240 in one hour and falling to about 200 until shortly before death, when the deep, slow Kussmaul respiration set in. The animal died in convulsions six hours after the administration of the lactic acid.

The alkali reserve of the blood was measured periodically in the Van Slyke apparatus¹⁰ on oxalated plasma. Prior to the experiment it was 44 volumes of carbon dioxide per hundred cubic centimeters of plasma. At thirty minutes it was 38, and just prior to death 33.

The findings at autopsy performed immediately after death were essentially as recorded previously. The stomach contained 144 Gm. of a semifluid brownish mass with some characteristic fecal pellets. It had a slightly sour odor. The pH was 3.30. The concentration of lactic acid was 1.91 per cent (w/v) and the total in the stomach contents was 275 Gm. As the amount originally administered was 10.1 Gm., there thus remained only 27.5 per cent unabsorbed after about six hours. This figure is in agreement with the determinations of Cori¹¹ on the rate of absorption of 12 to 15 per cent sodium lactate from the intestine of the rat. She found 25.8 per cent absorbed in the first hour, 44.9 per cent in the second, 59.1 per cent in the third and 69.7 per cent in the fourth. Our figure was 72.5 per cent in six hours. The concentration of lactic acid in the original solution, from which the feeding mixture was prepared, was determined after boiling for thirty minutes with excess of normal sodium hydroxide to hydrolyze the lactone and titrating the excess with normal hydrochloric acid. The concentration was 84.2 per cent.

RABBIT 3.—A similar experiment was carried out with another rabbit, except that the animal was allowed to swallow about 20 cc. of the acid milk mixture naturally. Measurement of the alkali reserve showed values of 67 at the start of the experiment, 38 after three hours and 43 after eight hours. The animal died during the following night, in approximately forty hours.

RABBIT 4.—A similar experiment on another animal fed 30 cc. of the acid milk mixture by stomach tube resulted in death with convulsions in ten minutes. There was no vomiting, but a blood stained froth was visible at the external nares and the lungs were noticeably edematous. In this case the stomach was so eroded that it ruptured on removal from the abdominal cavity. There were about 100 cc. of contents present.

COMMENT

From these observations and experiments it would seem obvious that lactic acid must be considered as a corrosive poison. The explanation of the deaths of the 3 babies is probably to be found in the administration of an acid milk mixture containing too high a concentration of lactic acid. This resulted in hemorrhage and erosion of the gastric and duodenal mucosa such that death resulted in toxemia from severe gastroenteritis. The interval prior to death was forty-five minutes in case 1, three and one-fourth hours in case 2 and fifteen and one-half hours in case 3. The rabbits died in ten minutes, two hours, six hours and about forty hours after identical doses. From the experiments with rabbits it does not appear as if the resulting acidemia was a major factor. That it has an effect, however, is apparent from the reduction in the alkali reserve of the blood. This aspect has been studied by Cohen,¹² who showed that intravenous injection of lactic acid at 0.045 Gm. per kilogram caused increased respiratory rhythm both in rate and amplitude but that the response was not specific for lactic acid. Rodler¹³ has also shown that lactic acid milk containing 6 Gm. per liter tended to produce an acidosis as measured by increased urinary acidity and decreased excretion of phosphate.

In comparison with the recognized toxicology of acetic acid it is not surprising that lactic acid, a much stronger acid, should also be considered as a corrosive poison. Due care should therefore be exercised in the labeling and dispensing of this reagent so commonly used in the feeding of infants.

SUMMARY

The deaths of 3 premature infants have been investigated, both pathologically and chemically, and found to be due to an acute hemorrhagic and gangrenous gastritis. The deaths occurred in 0.75, 4.25 and 15.5 hours following the administration of an acid milk mixture containing an excess of lactic acid. The 2 babies who were larger and lived longer also showed an acute enterocolitis, and the 1 who lived for 15.5 hours had, in addition, an acute catarrhal nephritis or nephrosis.

After administration by mouth of a lactic acid milk mixture containing 10.1 Gm. in 30 cc. to rabbits, death followed in ten minutes and two, six and forty hours in 4 animals. The symptoms and findings were identical with those of the infants and death was attributed to acute hemorrhagic gastritis. There was a moderate degree of acidosis.

Lactic acid must therefore be regarded as a corrosive poison, and due care must be exercised in its use as an infant food.

TYPICAL PARACHUTE INJURIES

A STUDY OF THOSE OCCURRING IN 250,000 JUMPS
AT THE PARACHUTE SCHOOLMAJOR C. DONALD LORD
ANDLIEUTENANT COLONEL JAMES W. COUTTS
MEDICAL CORPS, ARMY OF THE UNITED STATES

Parachute jumps at the Parachute School have increased progressively from their inception in 1941 to the time of this writing. Parachute injuries at the Parachute School have proportionately decreased progressively until at the present time a "jumper" has roughly only 1 per cent chance of being injured in any way in any one parachute descent. This remarkable increase in parachute activities, in spite of the decrease in injury rate, establishes a wealth of clinical material for study. This clinical material has been used in preparing this report.

Certain types of training injuries and jumping fractures have occurred repeatedly until there now exist several clinical entities recognized as typical parachute injuries. These will be discussed subsequently.

In this report we have analyzed the material at hand according to:

1. The type of injury most common to each of the four training stages and the anatomy, physiology and, where possible, the mechanics involved in producing the injury.
2. The immediate and follow-up care of the injured provided at the Parachute School.
3. New training technics and apparatus accounting for the diminishing injury rate.
4. New selection methods employed in choosing parachute personnel.

An "injury" has been arbitrarily chosen as a condition directly resulting from training which causes the student to lose one day or more from duty. Minor sprains, lacerations, contusions or exhaustive states which can be rehabilitated at the Parachute Medical Unit and returned to duty within a few hours are not considered statistically as "injuries."

The parachute course of training consists of four stages briefly described here for the purpose of orientation:

STAGE A.—Calisthenics, rope climbing, running and jumping from low 4 to 6 foot platforms into sawdust pits.

STAGE B.—Tumbling, trainasium, landing trainer, jumps from mock doors (4 to 6 feet), jumps from mock towers (30 to 35 feet) and suspended harness drill.

STAGE C.—Daily jumping from the 250 foot towers (free and controlled) and landing by parachute on sawdust. Tumbling is reviewed and parachute control is practiced.

STAGE D.—In which the applicant makes the necessary number of plane jumps to qualify as a parachutist, the jumps being made from a plane in flight and the landing being made on level and uneven terrain.

The physical hardening accomplished through stage A training put most applicants at something near physical perfection. It has been found that men physically

at their best are less prone to develop fear phenomena in the apparatus of the next three stages.

The right rectus muscle strain or tear has proved to be the most frequent cause of disability in stage A training and the most interesting clinically, since it closely simulates acute appendicitis. This occurs in rope climbing, presumably when the lower extremities are raised at right angles to the body and the legs grasp the rope, as shown in figure 1.

It is believed that in the attempt to reach the top of the rope an unusually strong effort is made, in some cases causing a definite sharp pain in the abdomen and resulting in the following clinical syndrome. The patient appears at the Parachute Medical Unit complaining of pain in the abdomen and walking slightly flexed at the hips. The simple process of getting on the examining table is difficult because of the pain. With the patient standing, the abdomen appears relaxed, there being no effort to "hold the abdomen in." In cases with hematoma formation a definite bulge can be seen along the course of the rectus muscle. Inspection further reveals some subcutaneous ecchymosis

Fig. 1.—Mechanism of right rectus muscle strain, or tear.

(after four to seven days have elapsed) extending downward from the point of maximum tenderness. The muscle is exquisitely tender on light palpation, and the patient resists any sort of deep pressure. When asked to raise the body from the prone position, keeping the lower extremities flat on the table, he experiences severe pain. Ninety per cent of these cases are in the right rectus and 10 per cent in the left. It is believed that this is due to the effort exerted being greater on the right side in the majority of cases. A white blood count of 9,000 to 11,000 occurs the day after the injury. Polymorphonuclear leukocytes range from 70 per cent to 80 per cent. Now that the cause is determined, the diagnosis can be readily made, but many have been hospitalized for observation for appendicitis. One patient was operated on. The wound was closed and the appendix not removed. A hematoma below the rectus was found.

Since the act of tumbling has proved effective in disseminating the shock of landing when contact is made with the ground, the proper technic of tumbling is drilled into the applicant over and over again daily until a smooth, properly executed tumble automatically follows contact with the ground from any height. This

Figures quoted were obtained from the official records of the Parachute School. Acknowledgment is made of the active cooperation of the X Ray and Orthopedic Services at Station Hospital, Fort Benning, Georgia.

Major Lord is Surgeon and Lieutenant Colonel Coutts is Assistant Commandant at the Parachute School. Both authors are qualified parachutists.

emphasis on tumbling leads to the typical injury of stage B, the acromioclavicular contusion and the acromioclavicular separation. Figures 2 and 3 show two training situations involving tumbles which are being properly executed.

Fig. 2.—Tumbling from the landing trainer. Arrow indicates point of most forcible contact with ground. If improperly executed, the point of the shoulder strikes with greatest force, resulting in acromioclavicular injury.

The shoulder tip should not touch the ground; the forearm held rigidly by the triceps acts as a bar over which the body rolls. When the triceps muscles are relaxed the shoulder comes in direct contact with the ground at point X, indicated by the arrow, and the acromioclavicular injury occurs. Separation of the acromioclavicular joint in these injuries involves only the tearing of the articular capsule in some cases, the coracoclavicular ligaments remaining intact, preventing the scapula and acromion from being displaced downward. In the more severe cases the capsule and the coracoclavicular ligaments are torn and the acromion, being completely separated from the clavicle, is displaced downward by the weight of the upper extremity. In figure 4 the acromioclavicular separation is pronounced but the scapula and acromion are depressed only slightly.

Fig. 3.—This illustrates in greater detail the mechanism of acromioclavicular injury.

In this case it was felt that the coracoclavicular ligaments were stretched but maintained the connection to the clavicle. This patient was treated with a block in the axilla strapped to the body; an additional strap extended up over the lateral end of the clavicle over the shoulder and down posteriorly attaching to the

block behind the axilla. The elbow was raised by means of a sling. The man returned to full jump duty after five months and has now qualified as a parachutist with no symptoms referable to the shoulder. The less severe injury, namely the simple acromioclavicular separation with slight, if any, tearing of the capsule responds to immobilization of the upper arm and shoulder for two to four weeks. Those patients are ready for full parachute duty in this length of time without any treatment other than physical therapy and rest.

In stages C and D the injuries have a common cause, namely landing via parachute. The injuries, while more frequent in stage D, involve the same mechanism and the two will be described together. There are two typical parachute leg injuries. The first typical parachute injury resulting from a parachute jump is the double fracture involving the lower third of the fibula and the posterior lip of the tibia. The mechanism of this fracture is explained on the basis of a double force. It is thought that the foot is rotated externally and forced posteriorly on contact with the ground when this fracture occurs. When the foot is rotated externally, the anterior portion of the body of the talus (astragalus) presses against the anterior border of the inner

Fig. 4.—Typical acromioclavicular separation.

surface of the external malleolus, forcing it outward and backward. If the force is sufficient and if the inferior tibiofibular ligament remains intact, this force tends to cause an oblique fracture of the lower end of the fibula, usually about 2 inches above the tip. The posterior force is the result of the forward motion of the foot as it strikes the ground. The impact is transmitted up the metatarsals, through the tarsus, forcing off the posterior tibial lip. In the presence of a ground wind and with oscillation at the time of landing a more violent eversion of the ankle may occur, resulting in the trimalleolar fracture described by Lewin¹ in his study of the foot and ankle. In these cases fracture of the internal and external malleoli and the posterior tibial lip occurs. This trimalleolar fracture, however, is considerably less frequent than that involving the fibula and posterior tibial lip alone.

Figure 5 shows the foot and leg position and landing attitude as the parachutist approaches the ground. Figure 6 shows a fracture of the ankle involving not only the usual lower end of the fibula and posterior tibial lip but also the internal malleolus, which occurs in the more violent eversions of the ankle with landing.

These fractures were common prior to some recent changes in landing attitudes. The "original parachute

1. Lewin, Philip. *The Foot and Ankle*, ed. 2, Philadelphia, Lea & Febiger, 1941.

fracture" has recently begun to be replaced by a fracture of the upper third of the fibula or dislocation of the fibular head. This is due to the greater support of the ankle by having both feet held firmly together at the moment of striking the ground. However, coin-

Fig 5.—Parachutists in descent. Preparation for contact with ground has been properly made.

cident with this decrease in this fracture there has been an increase in fractures of the upper third of the fibula and also in dislocation of the fibular head. Since the latter situation is simpler to handle surgically, and since the convalescent time is substantially less, this is considered a favorable change.

This second "typical parachute injury" we have called the "silent fracture," since frequently the upper third of the fibula will be fractured and the patient will exhibit few, if any, symptoms. It is not unusual that the fracture will occur in stage C and the soldier proceed with the actual plane jumps of stage D before reporting for medical care. Figure 7 shows a fractured fibula occurring on Friday of one week and being reported at the medical unit on Tuesday of the next week with "a little" pain. It is our belief that a fracture of the upper third of the fibula could very frequently be misdiagnosed as a strained muscle if the possibility of this "silent" fracture should not be kept in mind.

Such a relatively painless pathologic condition can undoubtedly occur only because the fibula does not enter into weight bearing. In a series of 35 cases diagnosed recently, only 10 were reported for treatment at the time of the fracture. The other 25 were reported for "slight pain" in the upper outer aspect of the leg seven to thirty days after the injury. Many showed definite callus formation at the original x-ray examination. It is felt that some cases of fractured upper third of the fibula are never diagnosed as fractures. They have become more frequent in our series as the lower fibula fractures decrease with the ankle support afforded by landing with the feet and ankles held firmly together.

Dislocations of the fibular head have occurred now in a small series of cases but are becoming more frequent as the ankle injuries diminish in frequency. Figure 8 shows the fibular head in a dislocated position.

It is felt that the sideward landings which occur in oscillations result in a tendency to "spring" the fibular head from its position or fracture it in the upper third.

Key and Conwell² mention the possibility of backward, forward, outward or upward dislocation of the fibular head. The dislocations of the fibular head occurring in the parachute landings are primarily lateral dislocations resulting from the "springing" action described. The attachment of the tendon of the biceps femoris would tend to dislocate it posteriorly and upward, but we have not seen this happen in our series. The diagnosis is not difficult, since the bone is subcutaneous and can be readily palpated. These dislocations are sometimes reduced on the jump field by the ambulance surgeon or at the parachute medical unit after x-ray examination. The procedure is strong inversion of the foot and direct pressure over the fibular head. An elastic bandage is applied and the patient put on crutches and kept ambulatory. We have seen no evidence of peroneal nerve involvement yet. One medical officer in parachute training having a dislocated fibular head reported a numbness of the foot lasting several days after the accident. There was no tendency to muscle weakness "or foot drop." We are of the opinion that the relations of the peroneal nerve to the fibular head are such that with slight or moderate dislocation of the fibular head no pressure is exerted on the nerve. Furthermore, reduction is accomplished very early in these cases, and if pressure on the nerve does occur it is relieved promptly.

These two clinical syndromes, one involving the ankle, the other involving the upper fibula, are showing signs of persistence of occurrence with thousands of jumps weekly and are now considered classic parachute entities.

With the opening shock of the parachute while the soldier is falling freely, any type of fracture or injury may occur if the body position is incorrect. The most unusual, recently, was a deep laceration of the perineum extending from the scrotum to and involving the sphincter ani and extending deeply, exposing the lower segment of the rectum. This was caused by the parachutist doing a forward somersault in the air with his legs apart before the parachute opened. The suspen-

Fig 6.—Typical parachute ankle fracture, involving both tibia and fibula

2. Key, J. A. and Conwell, H. E.: The Management of Fractures, Dislocations and Sprains, ed 3, St. Louis, C. V. Mosby Company, 1942.

sion lines went between his legs. When the parachute opened in the propeller blast, the great force of the taut suspension lines was exerted on the perineum, causing the deep laceration described. When the body position is normal, this great opening force is directed to the

body harness from the suspension lines. It is thought that this accident occurred because the parachutist "dived" rather than "jumped" from the plane in flight and because he neglected to keep his feet and legs together at the exit. Such cases are rare but are of great clinical interest because they show the hazards involved when the "rules" are not followed.

IMMEDIATE AND FOLLOW-UP PROVISIONS FOR CARE OF THE INJURED AT THE PARACHUTE SCHOOL

Fractures, discussed in this article, are seen long before swelling has time to occur, be-

Fig. 7—So-called silent parachute fracture of upper fibula. The term "silent fracture" has been coined to indicate the relatively painless nature of this fracture

cause of the preparedness which exists in the Parachute School for immediate handling of injuries. Frequently fractures can be palpated by the examining physician before the obscuring action of edema has intervened.

Injuries occurring in stages A, B and C are picked up by the ambulance from the Parachute Medical Unit within a few minutes from the time of the injury. Jumping injuries occurring in stage D are handled as follows: On the jumping field there is an aid man assigned to watch the descent of every parachutist. He is within 6 feet of the parachutist when the latter lands. If there is any evidence whatever of injury, the aid man unfolds his red flag. Two ambulances and doctors are assigned daily to the field. One responds immediately to a waving red flag. The diagnosis is made within a matter of two minutes, as a rule, from the time of injury. The injured member is splinted and transported to the Parachute Medical Unit, where x-ray films are taken. Wherever possible, if no fracture exists, ambulatory treatment is encouraged. Men with fractures are admitted to the hospital; men with sprains, regardless of their severity, contusions, and the like, are supplied with crutches and kept mobile.

On two occasions the Parachute Medical Unit has conducted a series of studies to determine the advisability of injecting procaine hydrochloride for sprains. The immediate relief of discomfort by this method cannot be disputed. However, with early icing, tight binders and the use of crutches for twenty-four hours the pain is not a troublesome problem. It is believed that procaine injection has definite value in chosen cases with severe pain or for those who must walk imme-

diately. The great majority, however, are not injected with procaine in our present method of treatment. The length of disability is not shortened by procaine injection in our series. This may be due to the fact that almost complete healing is required before a soldier is permitted to return to jumping status.

In the first twenty-four hours tight bands, icing and immobilization constitute the treatment of preference. After the first twenty-four hours warm applications, gentle massage and early active motion is the course followed. The physical therapy department in the Parachute Medical Unit handles hundreds of men daily, using infra-red lamps, ultraviolet rays, whirlpool baths, alternating hot and cold baths, and massage.

NEW TRAINING TECHNICS AND APPARATUS ACCOUNTING FOR THE DIMINISHING INJURY RATE

It is believed that certain revisions of the landing method taught at the Parachute School are in some measure responsible for a distinctly diminishing injury rate. This decrease was accomplished in spite of an increase in the training load of the Parachute School since July 1943. A revision of technic entailed:

1. Landing with the feet together, legs bent slightly at the knees, and the weight of the body slightly forward over the feet. Legs are held so that the knees are together. The muscles are not tensed, yet not relaxed. The leg muscles are alert to take up the landing shock.

Fig. 8—Typical dislocation of fibular head. Here, as in the "silent fracture," one notes a minimum of symptoms, which are infrequent.

2. A variation of previously taught tumbling technic so that proper landing can be made during ground approaches that are angular to the line of drift during a parachute descent. It was discovered that, although the desired approach was a forward drift then landing (fig. 5) in a large percentage of instances, backward or oblique landings occurred.

Further diminution of the injury rate was accomplished by exacting supervision of each student during this period of training before entering stage D. Careful attention to the maintenance of all equipment and training aids was found also to have some value.

Fig. 9.—Graphic representation of the fact that all injuries in both the jumping and the prejumping stage have been materially decreased. Weekly percentage includes injuries in all four stages of training.

A study of the parachutists in figures 3 and 5 shows the value of the training the candidate receives in stages A, B and C. Figure 5 indicates lessons in landing technic that were properly learned. In the early days of parachute training when the student load on the school was small, the assistant commandant was able to select the most favorable weather when jumping his novices for qualification. However, when it became necessary for the Parachute School to produce material increase in its output it became increasingly difficult to pick ideal jumping weather for the novice. The directive to "qualify the men" made it impossible to limit their jumping to ideal weather conditions as in the past. The decreased injury percentage appears all the more remarkable in view of these conditions.

Strong ground winds frequently set up a pendulum-like motion of the parachutist, in which the apex of the parachute is the fixed, and the parachutist himself the moving, end of the pendulum. This swinging motion, or oscillation, as it is termed, can materially reduce the parachutist's opportunity of making an uninjured landing. When the old method of landing was taught, the novice's feet were approximately the width of the hips apart when landing. It is apparent that a sideward oscillation would bring the landing shock of all the body's weight on one or the other foot. This increased the possibility of sprain or fracture. The new method of landing, i. e. with the feet together, distributes the landing shock with almost perfect equality to both feet and legs when coming in for an oscillating landing. Careful records maintained at the Medical Unit, the Parachute School, covering thousands of injuries, have permitted the preparation of the chart presented as figure 9.

The new method of landing was inaugurated in stage A on June 12, 1943. It will be noted that since that time there has been a decided decline in the combined weekly injury percentage. This average was not subjected to the violent fluctuations which had previously characterized it. Comparison of the 1943 seasonal averages with those of 1942 reveals that in each case the combined percentage is lower.

SELECTION METHODS EMPLOYED IN CHOOSING PARACHUTE PERSONNEL

The selection of parachute personnel is done with the utmost care. All incoming applicants to the school have first been examined by their unit medical officer, who is supplied with a copy of the physical requirements for parachute admission. This serves as a gross screening process in weeding out obviously poor material. On admission to the receiving battalion at the Parachute School, all men are subjected to an examination system at the Parachute Medical Unit which rules out anatomically and psychologically poor material. The men are passed through a series of rooms and individually examined from a psychiatric point of view with stress being laid on various phobias for the detection of any lack of desire for training of this severity. They then proceed through the various stages of the physical examination, with particular stress being placed on anything which is symptomatic at the time, such as old lumbosacral sprains, old painful fractures, old retracting scars and any history of symptoms referable to the head, such as dizziness, blackouts or fainting spells. Potential hernias are ruled out for fear of exaggeration while in training. All men with heart murmurs, unless they can be definitely proved to be functional, are ruled out. All men with questionable visual acuity without glasses are ruled out unless their vision is 20/40 or better bilaterally. Venereal disease disqualifies a man on the original examination. If venereal disease is contracted during the course of training, the soldier is immediately removed from parachute training and disqualified. The syphilitic patient who has had what is considered adequate treatment and whose blood and spinal fluid serologic reaction is negative is acceptable. These are not considered cases of active venereal disease. The elimination of these conditions results in between 10 and 15 per cent rejections of all applicants to the Parachute School reaching Fort Benning for training.

Further selection is accomplished through the observations of the stage leaders in noting hesitancy or actual inability to perform some of the preliminary low jumping procedures.

Fig. 10.—Parachutists in various stages of exit from plane. It is at this moment that occasional "freak" accidents occur.

Such selection standards result in the acceptance of the best men available. We are convinced that men physically perfect are less prone to injury in training than those with any physical impairment and therefore accredit some of the diminishing injury rate to the increasing severity of selection standards.

Four typical physical injuries are summarized. These are parachute entities, proved by their repeated occurrence in soldiers taking this course. Their frequency, it is felt, has been much reduced in the past six months, and those occurring now are recognized as incidental to the production of qualified parachutists.

CONCLUSIONS

1. This survey covers parachute descents at the Parachute School in excess of 250,000.
2. Statistically, any parachutist has only 1 per cent chance of injury in any one parachute descent, and this figure is decreasing.
3. Some typical medical parachute entities are now established: (a) right rectus muscle strain, (b) acromioclavicular contusions and separations, (c) fracture of the lower third of the fibula associated with fracture of the posterior tibial lip and (d) the "silent fracture" of the upper third of the fibula—and less frequently a dislocation of the fibular head. The fibula can be fractured in its upper third and be relatively asymptomatic; hence the designation "silent fracture."
4. Holding the feet together on contact with the ground, replacing the old method of holding the feet 18 inches apart on landing, has considerably reduced ankle fractures.

Clinical Notes, Suggestions and New Instruments

HEMANGIOMA OF THE KIDNEY

HUGH F. RIVES, M.D.
Fellow in Urology, Mayo Foundation
AND

THOMAS L. POOL, M.D.
ROCHESTER, MINN

Hemangioma of the kidney is a rare disease. Bell¹ found only 1 instance of hemangioma of the kidney in 30,000 necropsies. In this case the tumor was situated in the substance of the kidney, had not eroded into the renal pelvis and therefore had not caused any symptoms. Judd and Simon² in 1928 were able to find only 11 cases of hemangioma of the kidney reported in the literature and added 1 case which they had observed. In 1941 Riley and Swann³ made a comprehensive review of the literature and were able to collect only 36 authentic cases. They added 1 case which they had observed. Since that time several cases have been reported,⁴ but not enough to justify another compilation of collected cases.

Two cases of hemangioma of the kidney have been observed at the Mayo Clinic. One of these cases has been reported by Judd and Simon.² The other case will be reported in this paper.

REPORT OF CASE

A man aged 33 was referred to the clinic on May 20, 1941 for routine examination for induction into the Army. He stated that he previously had passed blood in his urine. As urinalysis did not disclose any abnormality and as he had not passed bloody urine for several months, it was felt that he possibly might have essential hematuria.

On April 6, 1943, approximately two years later, the patient was referred to the clinic by his family physician because of an attack of hematuria which had occurred two days previously.

Fig 1.—Urogram showing failure of left kidney to excrete radiopaque dye.

Fig. 2.—Pyelogram made after injection of contrast medium into pelvis of the left kidney.

When the patient was 8 years of age his mother had noticed that his urine was bloody. At the age of 18 years he first had noticed that his urine was bloody. At that time the attack

of hematuria had been accompanied by dull aching pain in the left flank. The severity of the pain had increased when he passed blood clots. He had been advised to rest in bed for one month. He later had a similar attack in 1932 and again in 1940.

Fig 3—Gross appearance of involved kidney.

When the patient was examined at the clinic, gross examination disclosed that the urine was bloody and contained a few clots. Physical examination did not disclose any abnormality. Microscopic examination of the urine revealed hematuria grade 3 (on the basis of 1 to 4) and an occasional pus corpuscle in each microscopic field as viewed under the high power objective. The concentration of hemoglobin was 13.5 Gm. per hundred cubic centimeters of blood. The erythrocyte count was 4,820,000 and the leukocyte count was 6,400 per cubic millimeter respectively. The value for the urea was 40 mg. per hundred cubic centimeters of blood. A serologic test for syphilis was negative, and roentgenographic examination of the thorax did not disclose any abnormality.

Excretory urography revealed that the right kidney probably was normal (fig. 1) although visualization of the contrast medium was indistinct. The left kidney did not excrete any of the radiopaque dye. Retrograde pyelography disclosed obliteration of the middle calix of the left kidney and flaring of the upper and lower calices (fig. 2). It was believed that the patient probably had multiple cysts or a tumor of the left kidney.

On May 13, 1943 an exploratory operation was performed. A combination of spinal and intravenous anesthesia was employed. The left kidney was approached through the usual posterolumbar incision. Grossly the kidney appeared as though it had been the site of repeated infarction. Because of the persistent hematuria and the urographic findings, the kidney was removed.

The kidney measured 13 by 7.5 by 8 cm. and weighed 302 Gm. A diffuse cavernous hemangioma, which measured 9 by 5 by 6 cm., involved the pyramidal portion of the kidney and prolongations of the tumor extended through the cortex to the capsule (fig. 3).

Microscopic examination of the tumor revealed blood vessels and sinuses which varied in size (fig. 4). These were lined with flattened endothelium, and some of them contained erythrocytes and leukocytes.

The renal tissue adjacent to the tumor was the site of chronic inflammation.

Convalescence was uneventful, and the patient was dismissed from the hospital on the twelfth day after the operation.

COMMENT

Hemangioma of the kidney is a rare tumor and its etiologic importance in cases of essential hematuria is not to be emphasized; however, it may be the cause of bleeding of undetermined origin more often than one might suspect, but in the light of Bell's findings this is unlikely. It is, however, a lesion to be remembered in case of essential hematuria and there often is little evidence that one is dealing with such a tumor. Judd and Simon said that this type of tumor rarely was more than 2 cm. in diameter.

Fig 4.—Sections of hemangioma of kidney showing difference in size of sinuses and blood vessels ($\times 40$).

The symptoms of hemangioma of the kidney are hematuria, renal colic and the passage of clots. Frequently the bleeding is so profuse that an emergency nephrectomy is indicated. The treatment of this type of tumor consists in removal of the involved kidney.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, Secretary.

GUTH GERMICIDAL LAMP ACCEPTABLE

Manufacturer of Fixtures: Edwin F. Guth Company, 2615 Washington Avenue, St. Louis.

Manufacturer of Burners: General Electric Company, Lamp Division, Nela Park, Cleveland.

Edwin F. Guth Company presented the following apparatus for Council consideration: (1) the Guth Bracket Unit, (2) Guth Ceiling Unit, (3) Special type of Guth Bracket Unit, (4) Guth Baby-cubicle units and (5) Hospital Operating room unit, all of which are for permanent installation. The firm also submitted (6) floor unit, a standard and deluxe model and another fixture called the (7) "Guth Under-Bed Type," which irradiates the floor.

Clinical evidence submitted to the Council on Physical Medicine demonstrates that under properly controlled conditions the killing of air borne micro-organisms by ultraviolet rays may be used to

supplement other methods of disinfecting air for prevention of cross infection in contagious wards, in nurseries and for reducing air borne infection of wounds in hospital operating rooms. Council acceptance is limited to ultraviolet disinfecting lamps designed for installation in hospital nurseries, hospital wards and operating rooms.

The General Electric Germicidal Lamps manufactured by the General Electric Company, Lamp Department, Nela Park, Cleveland, have been mounted in fixtures manufactured by the Edwin F. Guth Company. The burner or source of ultraviolet radiation and the several fixtures have been examined by the Council. The characteristics as given for General Electric Germicidal Lamps are presented in the accompanying table.

Characteristics of the General Electric Germicidal Lamps

	G. E. Germicidal 30 Watt	G. E. Germicidal 15 Watt
Glass types	974 glass	974 glass
Lamp watts are ballast.....	30 + 10	15 + 5
Length in sockets.....	36 in.	18 in.
Milliwatts, 2,537 angstroms.....	9,000 10,500	3,600 4,200
Max. Int. Microwatts/cm ² 1 m.....	100 117	40-46
Max. Int. Microwatts/cm ² 1 ft.	740 840	300 310
Lamp life hours, three hour operating interval	2,500	2,500
Lamp life hours, continuous operation	4,000	4,000

The ultraviolet radiation is confined almost entirely to the wavelength 2,537 angstroms. Fixtures should be designed and installed to insure little or no direct irradiation of the individuals in the rooms.

When first installed the radiant ultraviolet energy is considerably more intense than 20 microwatts per square centimeter at 1 meter, recognized by the Council as being the minimum intensity for acceptance. As the lamps age the intensity drops off rapidly at first and more slowly later on. Under ordinary usage the lamps maintain the acceptable minimum intensity or above for the guaranteed period of four thousand hours of continuous operation. If, however, the lamps fall below this intensity before the guaranteed period has elapsed, the firm will make an adjustment on a pro rata basis. Users of the equipment are advised to test the lamps each month to determine whether they are up to standard. Since the lamps burn at a characteristic color constantly there is no way of determining

whether they are emitting sufficient ultraviolet radiation except by testing them with an ultraviolet meter.

Satisfactory evidence is not available to warrant acceptance of ultraviolet lamps for disinfecting solids. To kill a micro-organism a direct hit by ultraviolet rays of sufficient intensity is required. This is difficult to accomplish on the edge of a drinking cup, for example, also in a liquid containing suspended matter or in air laden with dust particles that shield the organism. Ultraviolet radiation cannot penetrate deeply and hence may be absorbed by finger marks, saliva, cosmetics or other foreign matter on a drinking cup. In view of the present available evidence, ultraviolet radiation appears to be an uncertain means of sterilizing solid objects (drinking cups, combs, brushes, shaving utensils, toilet seats and shoes) even if irradiation of the whole surface is possible. Ultraviolet lamps for disinfecting purposes are not accepted for disinfecting air in schools, waiting rooms, public gathering places and large halls. The evidence now available does not indicate that the incidence of colds can be reduced by the installation of ultraviolet lamps or by the irradiation of an enclosure occupied by people.

The Council on Physical Medicine voted to accept the Guth Germicidal lamps for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN E. SMITH, M.D., Secretary.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 608).

The following dosage form has been accepted:

HORTON & CONVERSE, LOS ANGELES

Tablets Thiamine Hydrochloride: 1 mg.

SULFADIAZINE (See New and Nonofficial Remedies, 1944, p. 178).

The following dosage form has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Sulfadiazine (Powder): 120 Gm. and 453 Gm. packages.

SULFAMERAZINE (See THE JOURNAL, May 6, 1944, p. 31).

The following dosage form has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Sulfamerazine (Powder): 120 Gm. and 453 Gm. packages.

SULFANILAMIDE (See New and Nonofficial Remedies, 1944, p. 184).

The following dosage form has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Sulfanilamide (Powder): 120 Gm. and 453 Gm. packages.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1944, p. 191).

The following dosage form has been accepted:

LEDERLE LABORATORIES, INC., PEARL RIVER, N. Y.

Sulfathiazole (Powder): 120 Gm. and 453 Gm. packages.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1944, p. 418).

The following dosage forms have been accepted:

WILLIAM R. WARNER & CO., INC., NEW YORK

Tablets Diethylstilbestrol: 0.1 mg. and 1 mg.

Ampuls Diethylstilbestrol (in oil), 1 mg. per cc.: 1 cc.

Diethylstilbestrol (in oil), 1 mg. per cc.: 10 cc. multiple dose serum capped vials, containing 0.5 per cent chlorobutanol.

THE PREVENTION OF CANCER

In a recent and interesting discussion¹ of preventive medicine occurs the statement:

Prompt and aggressive treatment—a purely curative process—takes on a strongly preventive coloring because it may forestall serious deterioration or death. This is true also of cancer, a nonpreventable disease of unknown cause which can nevertheless be cured in many instances by surgical removal or radiological destruction of the lesion. The full use of modern diagnostic facilities permits such intervention at a profitable stage in many cases of cancer which would otherwise go unrecognized until they were incurable. The gastrointestinal x-ray study which a careful diagnostician orders when confronted with certain abdominal symptoms is thus an important tool of preventive medicine.

Suffering and death from cancer are prevented by its cure and in that respect cancer is preventable. But the remark that cancer is a nonpreventable disease, presumably in the sense that its onset cannot be prevented, and of unknown cause is open to question.

The causes of cancer are by no means unknown. Experiments have demonstrated that a large number of substances can cause cancer. True, the exact mechanism of cancer causation is not understood. Neither do we understand just how the tubercle bacillus causes tuberculosis. Our knowledge of these and other more or less similar mechanisms is as yet mainly in the observational and descriptive stage.

There are many examples of cancer in man that arise under the influence of particular agents under such circumstances that there can be no doubt as to cause and effect. One of these is chimney sweeps' cancer of the skin, recognized by Percival Pott in 1775 as due to the action of soot, from which cancerigenic chemicals have been isolated in recent times. Other examples are mule spinners' cancer, due to mineral oil; cancer of the skin in tar workers; cancer of the lip in fishermen repairing tarred nets; cancer in workers with aniline dyes, and cancer in x-ray and in radium workers. In other cancers the causative condition is obvious but

the precise agent is not known. This is the case of cancer at a spot where the mucous membrane of the mouth has been rubbed by a ragged tooth or an ill fitting denture or at the spot on the cheek against which the quid of chewing tobacco has been held perhaps for years. In cattle cancer may arise at the root of the horns where the traction rope runs back and forth. In industries cancerigenic chemicals are used which on entrance into the bodies of workers may cause preventable cancer. The successful results of planned experiments could not be more convincing of the preventability of human cancer than these and other clinical examples. Generally speaking, the association of cancer with chronic inflammatory and irritating lesions—"pre-cancerous conditions"—is so close that their prevention and cure are regarded by physicians as all important measures toward the prevention of cancer. A movement is under way toward the establishment of clinics for cancer prevention. All the efforts to control cancer are based on the possibility of preventing its start as well as its advance.

JAUNDICE FOLLOWING VACCINATION AGAINST YELLOW FEVER

Jaundice occurring in army units stationed largely in this country and associated with vaccination against yellow fever received much publicity about two years ago. Now an exhaustive report has appeared of a study made by a research team appointed by the Surgeon General of the Army to investigate this problem.¹ The report deals with jaundice in army personnel in the western region of the United States and its relation to vaccination against yellow fever.

The greater part of the jaundice which was epidemic in army personnel in the western region of the United States from March to July 1942, it was found, was a hepatitis similar to the common so-called catarrhal jaundice or infectious hepatitis in its manifestations but related to the injection of certain lots of yellow fever vaccines from sixty to one hundred and fifty days before the attacks. The total number of reported cases of jaundice of the type under study in the western region as defined was 11,853, and the records of 10,284 were subjected to statistical analysis. In the latter group there were 31 fatalities, or a mortality rate of 3 per thousand cases. The absence of a noticeable increase in jaundice in navy personnel and in foreign countries where yellow fever vaccines from the same source were used was found to be due to the fact that definitely icterogenic lots of vaccine were not employed in either of those large groups. Although the exact nature of the icterogenic agent in the vaccine could

1. Sawyer, W. A.; Meyer, K. F.; Eaton, M. D.; Bauer, J. H.; Putnam, Persis, and Schwenker, F. F. Jaundice in Army Personnel in the Western Region of the United States and Its Relation to Vaccination Against Yellow Fever, *Am. J. Hyg.* 93: 337 (June), 10: 35 (July) 1944.

1. Smith, G., and Evans, L. J.: Preventive Medicine: An Attempt at a Definition, *Science* 100: 39 (July 21) 1944.

not be determined, the following possibilities were definitely ruled out: that it was due to the modified yellow fever virus in the vaccine, to insanitary conditions, to food or water, to contact with any chemical poison, to inoculation to prevent diseases other than yellow fever or to any local or environmental factor. The most plausible hypothesis as to the source and nature of the agent was that it had been introduced into the vaccine in human blood serums secured from presumably normal donors and that the agent was most probably an unknown filtrable virus capable of causing disease in man and occasionally of circulating subsequently in the blood during a prolonged carrier state. Unfortunately, extensive attempts to isolate the supposed virus agent were either completely negative or gave only suggestive results.

On April 13, 1942, as the result of its first investigations into the subject, the commission's principal recommendation to the Surgeon General of the Army was "That, as far as military exigencies permit, vaccination with lots with numbers over 330 be suspended for at least two months for the purpose of permitting the completion of the investigations in progress and allowing any delayed manifestations to appear and indicate whether later lots are safe. . . ." The final report of the investigative team included the important recommendation that only serum-free yellow fever vaccine be utilized in the immunization of military personnel against yellow fever. That this recommendation was a practical one is due to an extraordinary development: during the course of the investigation the two laboratories which had been preparing the vaccine in the United States devised methods to modify their technic so that human serum could be omitted from a still potent vaccine!

While the problem of jaundice following vaccination against yellow fever may have been completely solved by the removal of human serum from the vaccine, the result of transferring the icterogenic agent may be more difficult to eliminate in other serum-containing biologic products. All possible encouragement and assistance should therefore be given to research aiming to isolate the causative agent of postinoculation jaundice, devising methods for protection and of finding ways of excluding it from all of the serum-containing biologic products.

Prompt and intelligent action here served to place under rapid control an unanticipated complication resulting from the development of a new prophylactic procedure of enormous value. The entire handling of this unexpected mischance reflects great credit on the Office of the Surgeon General of the Army and on all those who took part in the investigations.

MENSTRUAL TOXIN

In 1940 the Smiths¹ of the Free Hospital for Women, Brookline, Mass., tested the toxicity of 37 normal menstrual discharges from parous women. These discharges were often highly toxic for rats. Thirty-five of the thirty-seven specimens produced death within forty-eight hours in 19 to 24 day old female rats, when given twice daily in doses varying from 0.01 to 0.8 cc. The two apparently nontoxic specimens were from the same donor and had been collected during the first day of the menstrual flow. Later specimens from the same donor killed rats in doses varying from 0.1 cc. to as little as 0.01 cc. The most constant lesions found at necropsy in these rats were diffuse or focal hemorrhages of the adrenal cortex with dissolution of cells in either or all zones. In rats that died, early hemorrhage was the only finding. Less constant necropsy findings were hemorrhagic and edematous lesions of the lungs, liver and kidneys, with blood occasionally found in the urinary bladder. With increased length of survival, dissolution to actual necrosis of the parenchymatous cells was also seen. There was usually a brawny induration at the site of the subcutaneous injection.

Male rats and spayed immature females are relatively unsusceptible to this toxin. The susceptibility of normal females varies with the estrous period. Females injected at the beginning of postestrus are most likely to survive. If each dose of the menstrual discharge is accompanied by a subcutaneous injection of 0.05 microgram of estradiol, female rats almost invariably die within forty-eight hours after the first injection, regardless of the time of the cycle. Female rats can be protected against a lethal dose of the toxin, or of the toxin plus estrogen, by preliminary or simultaneous administration of large amounts of progesterone.

Female rats may be immunized against several times the usual minimum lethal dose of the toxin by six biweekly subcutaneous injections of sublethal doses of the toxin, the resulting immunity persisting for at least four months. Mature female rabbits are also extremely susceptible to the discharge, one to three subcutaneous injections of 1 cc. of the menstrual discharge usually resulting in death within forty-eight hours. Rabbits, however, can be immunized by multiple sublethal doses. The serum from such rabbits contains specific precipitins for the toxin. Given in five 1 cc. doses two and a half days prior to the injection of the toxin, this antiserum will protect immature female rats against twice the usual minimum lethal dose of the toxin.

Subsequently these investigators² found that when the menstrual discharge is centrifuged a buffy coat or

2. Smith, O. W., and Smith, G. V. S.: *Proc. Soc. Exper. Biol. & Med.* 55: 285 (April) 1944.

middle layer of endometrial debris is formed between the serum and the sedimented red blood corpuscles. This layer is ten times more toxic than the supernatant serum. The sedimented blood cells are practically non-toxic. During the catamenial flow the toxicity of different samples varies in direct proportion to the amount of endometrial debris, suggesting that the menstrual toxin is an autolytic product of the decidua menstrualis. This theory is confirmed by repeated failures to produce a similar toxin by the aseptic autolysis of human venous blood or by disintegration of such blood after inoculation with menstrual flora.

After precipitation with one-third saturated ammonium sulfate the toxicity is most concentrated in the water insoluble portion (after dialysis) of the euglobulin precipitate. Further purification of the toxin is hampered by its lability. Partially purified toxin often loses most of its potency while being dried in a Florsdorf-Mudd apparatus. The best preparation thus far obtained was a grayish white powder, killing rats in doses equivalent to 0.75 cc. of menstrual serum. Even the fully dried precipitate rapidly deteriorates, losing three fourths of its toxicity within six weeks.

The nearest approach to the menstrual toxin thus far reported in biochemical literature is the toxic euglobulin in human inflammatory exudate recently described by Menkin,³ which he named "necrosin." Detailed studies of the relation of "necrosin" to the menstrual toxin are now in progress.

TICK TRANSMISSION OF ENCEPHALITIS

Since the St. Louis epidemic of 1933, many clinicians have assumed that epidemics of acute encephalitis are due to person-to-person droplet infection. The causative agent of the disease, however, has never been isolated from nasopharyngeal washings, and the seasonal variations and topographic distribution strongly suggest an insect vector. Following Syverton's¹ experimental transmission of western type equine encephalomyelitis by means of the wood tick, and the implication of several species of ticks by Soviet investigators,² Blattner and Heys³ of the Department of Pediatrics, Washington University School of Medicine, began a study of the relation of the St. Louis encephalitis virus to the common dog tick (*Dermacentor variabilis*).

The dog tick is relatively common in the environs of St. Louis and is readily reared under laboratory conditions. Adult females feeding on guinea pigs or hamsters require on an average four to six days for complete engorgement. Four days later eggs are laid. Within fifteen days at ordinary room temperature these

eggs develop into typical six legged larvae. Within ten days after an initial blood meal (white mice) the larvae metamorphose into eight legged nymphs. These in turn become eight legged adults in six to eight days after an additional feeding. A blood meal is required before each metamorphosis. If not fed, the tick enters a diapause or latent stage at any stage of development. Under optimum feeding conditions the life cycle may be as short as forty-five to fifty days but may be extended to two years or more under less favorable conditions. The ticks may survive a winter in any stage of development.

Tests with hamsters showed that the virus is present in the blood stream from six hours to seventy-two hours after intraperitoneal inoculation with St. Louis encephalitis. A similar transient viremia is noted in mice inoculated intracerebrally. Larvae, nymphs and adult ticks were allowed to feed on infected mice or hamsters during the viremic phase, after which they were transferred to normal white Swiss mice. In nine to fourteen days signs of illness were noted in the second host. With young mice the resulting tick borne infection was usually fatal. Older mice often recovered, eight to twelve weeks later their serums showing the presence of high titer antibodies against St. Louis encephalitis. Many convalescent adults would withstand as much as 10,000 minimum lethal doses of the St. Louis virus injected intracerebrally.

The virus is present in lethal concentration in the eggs of infected female dog ticks and in the larvae, nymphs and adult forms developing from these eggs. It is also present in lethal concentration in the eggs and all stages of development of the second generation. Although the tests have not yet extended beyond the second generation, it seems probable that the virus can be transmitted indefinitely in the progeny of an infected female tick. The virus can remain viable in infected eggs or in the bodies of hereditarily infected ticks which are kept dormant as long as ten months, by storage at 12.5 C.

The St. Louis pediatricians do not believe, however, that the dog tick is the vector responsible for the transmission of St. Louis encephalitis to man, since a history of tick bite was not recorded in the 1933 epidemic. They believe that the dog tick, feeding on birds and mammals, may play an important role in establishing and maintaining a reservoir of infection in nature, from which human beings may be infected by other blood sucking insects. Recent work by Hammon,⁴ Howitt⁵ and their associates has shown the natural occurrence of St. Louis encephalitis virus in *Culex tarsalis* and other species of mosquitoes, as well as of type specific

antibodies in the blood of numerous species of mammals and birds. They have demonstrated experimental transmission of the St. Louis virus to birds by means of bites from nine species of infected mosquitoes.

The work of Blattner and Heys is the first successful transmission of St. Louis encephalitis to experimental animals by means of ticks and is thus a confirmation and extension of work recently reported by Soviet epidemiologists.²

Current Comment

POLIOMYELITIS VIRUS IN THE HUMAN OROPHARYNX

Emphasis on the presence of poliomyelitis virus in the feces has tended to retard attempts to isolate the virus from other human sources. Now Howe and his colleagues¹ report on the study of throat swabs taken from 14 cases of acute poliomyelitis during the first week of the disease. Instead of nasal or pharyngeal washings often formerly used, they employed cotton swabs rubbed against the posterior wall of the oropharynx and the peritonsillar area. The swab was then detached, dropped into a fluid tight container with 1 cc. of sterile water and stored on solidified carbon dioxide. The technic of inoculation was as follows: The throat swabs were washed out in phosphate buffer at p_H 8, the fluid being pressed out of the cotton in a syringe. The eluate was then brought to p_H 6 and treated with 20 per cent ether in the ice box until sterile (usually thirty-six hours), at which time the ether was removed. In no case was more than 1.1 cc. of inoculum obtained. Rhesus monkeys of 8 to 10 pounds were inoculated in each lateral thalamus under ether anesthesia. Of the 14 specimens tested (which were unselected from a larger series), 7 produced typical poliomyelitis in the test animals. Six of the 7 animals were paralytic. Microscopic sections showed characteristic lesions in each case. There seems little doubt that the infectious agent was present in the oropharynx and can be definitely transmitted by the technic described.

THE Rh FACTOR IN FEEBLEMINDEDNESS

The importance of the Rh factor in fetal erythroblastosis and in unfavorable reactions in transfusion under certain circumstances is well established. The Rh factor in the blood of a fetus where the father is Rh positive can lead to the production of antibodies in an Rh negative mother, which in turn can destroy red corpuscles in the fetus leading to fetal anemia and its consequences. Now a beginning has been made in the study of the possible relationship of the Rh factor to mental deficiency. Yannet and Lieberman found that, in the case of 53 children with mongolism, birth trauma and other specific types of feeble-mindedness, the distribution of the mothers as to Rh positive and Rh negative corresponded closely to the accepted normal

white average in the United States. In the case of 56 children with mental deficiencies of unclassified nature, however, 14 of the mothers were Rh negative, which is more than twice the average for the general population. Of these 14 Rh negative mothers 11 had Rh positive children. While the number of cases in this series is too small to have any statistical significance, further study on a much larger scale of the Rh factor in feeble-mindedness seems advisable. Commenting on the work of Yannet and Lieberman, Cook¹ points out that destruction of fetal blood cells by anti-Rh bodies in the blood of mothers may lead to serious injury to the fetal brain from anoxia, possibly also in other ways. In fetal erythroblastosis and icterus, degenerative changes in cerebral structures (kernicterus) may occur on a large scale. The idea that the Rh factor may play a role in feeble-mindedness turns the attention to the possibility of preventing its disastrous effects. It has been suggested that tests of the blood for anti-Rh agglutinins in pregnant Rh negative women may give warning of the danger of fetal erythroblastosis and thus facilitate appropriate treatment immediately after birth. Further developments of great interest in the understanding of the Rh factor and its effects are foreseen.

INSULIN REQUIREMENT OF MAN AFTER TOTAL PANCREATECTOMY

Complete removal of the pancreas in man should furnish evidence as to the basic insulin requirements: the greatest need should exist when insulin is not produced at all. The truth of this expectation has become a problem of increased clinical importance with the development of modern pancreatic surgery. Observations on two men after total pancreatectomy by Goldner and Clark¹ revealed unexpectedly small insulin requirements and great insulin sensitivity. Pancreatectomy in both cases was performed because of neoplastic growth. During the periods of observation the patients did not receive any nourishment by mouth but were given several blood transfusions and 100 to 150 Gm. of dextrose daily, intravenously, in the form of a 5 per cent solution. One patient also received infusions of casein hydrolysate. Urinalysis and blood sugar estimations were made at regular intervals. A solution of insulin zinc crystals was also added to the dextrose solution and thus entered the system slowly. The first patient excreted 1 to 2 Gm. of dextrose in a urinary volume of 1,500 to 2,000 cc. and the second patient was free at first, becoming anuric later. The first patient received four infusions of 1,000 cc. of 5 per cent dextrose solution within the first thirty-six hours. When the blood sugar had reached 292 mg. per hundred cubic centimeters, 20 units of insulin without dextrose was given. Six hours later a severe hypoglycemic reaction occurred and the blood sugar had dropped to 14 mg. per hundred cubic centimeters. Intravenous injection of 50 Gm. of dextrose resulted in the return of the

1. Goldner, Martin G., and Clark, Dwight E.: The Insulin Requirement of Man After Total Pancreatectomy, *J. Clin. Endocrinol.* 4: 194 (May) 1944.

1. Howe, Howard A., and others: Poliomyelitis Virus in the Human Oropharynx, *Proc. Soc. Exper. Biol. & Med.* 56: 171 (June) 1944.

blood sugar level to normal, 127 mg. per hundred cubic centimeters. Insulin was not added to the venoclyses until forty-eight hours later, when the blood sugar had reached 410 mg. per hundred cubic centimeters. The administration of insulin was then resumed, with 5 units. The doses were increased gradually to 10, 15 and 20 units, and no insulin was given without simultaneous dextrose infusion. On this management it was found possible to maintain the blood sugar between 90 and 200 mg. per hundred cubic centimeters and to avoid further hypoglycemic reactions. Thus the daily insulin requirement was only about 50 units on a dextrose intake of 150 to 200 Gm. The course of blood sugar and relation between insulin and hypoglycemia were roughly the same in the second patient. It can be concluded that the depancreatized man requires less insulin and is more sensitive to insulin than many diabetic patients. The question consequently arises as to whether in the causation of diabetes not only lack of insulin but also an insulin inhibiting mechanism may play a part. The line of investigation suggested may throw new significance on the etiology of human diabetes mellitus.

THE NATIONAL FORMULARY MOVES FORWARD

The National Formulary is recognized as an official compendium of certain selected drugs and preparations for the United States. Now the National Formulary is undergoing changes which will effect much improvement. Over 190 drugs, nearly one third of the monographs in N. F. VII, are tentatively slated for deletion from N. F. VIII. Included in these deletions are many preparations that have been obsolete for many years and which at best could never be called truly effective therapeutic agents. Another progressive step is the adoption of English titles in preference to Latin. This change will be hailed by teachers, students and practitioners. Further, the metric system is now used in N. F. monographs, except that doses are given in metric and apothecary systems. The proposed list of additions for N. F. VIII contains a few agents not generally held necessary, but the bulk represent a trend that is most commendable. The National Formulary, United States Pharmacopeia and New and Nonofficial Remedies should be available to every physician.

DANGER OF RABIES INCREASING

Throughout the country the reported increase of rabies in dogs is a cause of mounting concern. Control measures have been instituted in many areas, including parts of southern California, eighteen Michigan counties, St. Louis, the environs of Baltimore and Newport, Ky. Reports from Indiana and the Bronx indicate an increase in the number of rabid dogs and of persons bitten by rabid dogs. If still more serious outbreaks are to be forestalled, such well known preventive measures as muzzling, incarceration and destruction of stray animals, and restraining of all owned dogs by leash will doubtless have to be undertaken in many other communities.

EPIDEMIC OF RINGWORM OF THE SCALP IN NEW YORK CITY

An epidemic of tinea capitis in New York City caused by *Microsporon audouini* and involving several thousand children has been reported as spreading for more than a year. Tinea capitis has become more frequent in many other large cities; an epidemic status, however, is a unique situation for this country. Epidemics of ringworm of the scalp were known in France, where infected children were sent to separate schools. A committee appointed by the Association of Dermatosyphilologists of Greater New York,¹ to study this problem suggests the following as possible causes of this epidemic: 1. Decreased maternal care and supervision because mothers are employed in factories and offices. 2. Countrywide change of residence of members of the armed forces and war workers. Infected children are moved from place to place, traveling with their parents to new locales. 3. Overcrowding in children's institutions and a rapid turnover in these institutions. Inefficient supervision, partly because of lack of personnel and equipment. Infected children may have been known to be discharged to their homes from state institutions. 4. Possibility of spread of the infection through the medium of barber shops and moving picture houses, the backs of subway seats, and other inanimate contacts. Infected hairs have been found in an East Harlem moving picture house. There is no evidence of increased pathogenicity of *M. audouini* from limited animal experimentation and tests with trichophytin. The first diagnostic center to study the extent of the infection, to assist in diagnosis and to advise practitioners was established in the Astoria health district, where an unusual number of children with infected scalps was reported. All children attending school were examined under filtered ultraviolet rays (Wood light). Infected children were treated with x-rays. After the patient was considered cured by the clinic or doctor, two consecutive negative examinations by the diagnostic center, a week apart, were required before the child could return to school. Based on the Astoria demonstration, the committee made the following recommendations for the control of the epidemic in New York City: 1. Case finding: Tinea capitis should be made a reportable disease; as a preliminary step to control, it is essential to make a citywide case finding survey of all school children, using filtered ultraviolet rays; the case finding survey should be reported every three months; when cases are found, a district diagnostic center should be set up. 2. Education of the public: The public should be reached through the press, from pamphlets and by the radio. 3. Institutions. It is recommended that citywide, complete and periodic inspection of children who are in institutions be made by qualified physicians. Infections caused by *Microsporon audouini* should promptly receive the benefit of x-ray therapy. Local measures are usually ineffective. Communities free of the disease should take active steps to prevent the disease or to localize any nidus that appears.

1. Lewis, George M.; Silvers, Seymour H.; Cipollaro, Anthony C.; Muskatblit, Emanuel, and Mitchell, Harold H. Measures to Prevent and Control an Epidemic of Ringworm of the Scalp, New York State J. Med. 44: 1237 (June 15) 1944.

MEDICINE AND THE WAR

ARMY

HEALTH IN PACIFIC AREAS

[The following is a letter received by Major General Norman T. Kirk from the Honorable Nelson Trusler Johnson, Minister to Australia.]

THE FOREIGN SERVICE OF THE UNITED STATES OF AMERICA AMERICAN LEGATION

Canberra, Australia
June 7, 1944.

Dear General:

I have just returned from a trip in the Pacific areas where American forces are established and working, except for the combat areas. The work which our army medical services have done is so remarkable and so amazingly successful that I felt that I must sit down to write and tell you this.

Certainly these are impossible areas for a white man to live and work in, but I did not see or hear a mosquito the whole time I was there and the records of the various commands and the hospitals show that, through the efficiency of the control planned and carried out in all of these areas, amazing things have been accomplished so that malaria is no longer the threat to success of our mission in this area of war.

I wish I could mention by name all of the officers and men connected with this service I met and saw working, because it is a tribute to each and every one of these men, from the highest to the lowest, that such amazing things have been accomplished in so short a time in a country where, at the beginning of the campaign, it really looked as though the malarial mosquito was going to lick us even before the Japanese got to us.

With kindest regards, I am

Sincerely yours,
NELSON TRUSLER JOHNSON,
Envoy Extraordinary and Minister
Plenipotentiary to Australia.

Major General N. T. Kirk,
Surgeon General,
Army Medical Center,
Washington, D. C.

PLANS IN PROGRESS FOR ARMY MEDICAL HISTORY

At a meeting of representatives of the professional and administrative services of the Office of the Surgeon General, held in Washington, July 26, plans were discussed and progress reports made on the medical history of the war. Work on the history has been in progress since August 1941 under the direction of Col. Albert G. Love, who was a member of the editorial staff that published the history of the Medical Department of the United States Army in World War I. Editors have been selected for the volumes on the medical specialties and the administrative phases of the medical service. In addition to the research and editorial work to be done in the Office of the Surgeon General, historical activities will be carried forward by officers assigned to headquarters of overseas theaters. They will secure first hand reports of the overall medical services, particularly those rendered under combat conditions including evacuation of the wounded, the flow of supplies and other problems. Officers in overseas theaters who have had extensive experience with medical and surgical problems peculiar to this war are being asked to record their observations for the history.

When first organized, historical activities of the Medical Department relative to professional subjects were part of a joint

plan to be undertaken in cooperation with the Subcommittee on Historical Records of the Division of Medical Sciences of the National Research Council. The administrative and organizational volumes were to be prepared by the Medical Department. This plan, however, was modified recently in accordance with the wishes of Surg. Gen. Norman T. Kirk. General Kirk felt that the Medical Department should assume full responsibility for its entire history in view of the global scope of the work and the consequent necessity of having the history prepared by officers who have been intimately associated with the practice of military medicine throughout the world.

Medical histories were published by the Office of the Surgeon General following the Civil War and the first world war. The volumes have done much to perpetuate and disseminate professional, administrative and organizational medical advances developed under the impetus of war.

British authorities are carrying forward a similar plan for recording the medical history of the current war.

BRIG. GEN. CHARLES C. HILLMAN IN COMMAND OF LETTERMAN GENERAL HOSPITAL

After five years as chief of the professional service of the Office of the Surgeon General, Brig. Gen. Charles C. Hillman left Washington August 7 to take up his new post as commanding general of the Letterman General Hospital, San Francisco. This hospital, containing 2,500 beds, has been designated as the principal debarkation hospital for casualties from the Pacific area. General Hillman will succeed Brig. Gen. Frank T. Weed, who will soon retire. Major Gen. Norman T. Kirk, Surgeon General, U. S. Army, stated that "General Hillman's assignment as the commanding general of this important hospital on the West Coast illustrates the Army's concern with the care of sick and wounded soldiers. It is of paramount importance that such work be carried out under the direction of a medical man of wide experience and sound judgment. He has ably directed our professional service, being mainly responsible for the initiation of the blood plasma program of the Army, resulting in saving the lives of thousands of American soldiers; under his direction was organized the chest x-ray examination of all Army inductees, with a lowering of the incidence of tuberculosis among military personnel to less than one-tenth that in World War I."

General Hillman graduated from Rush Medical College, Chicago, in 1911. Following his internship in the Cook County Hospital, Chicago, he entered the Army Medical Corps in 1912. His assignments have been largely professional in character in important medical centers of the Army. His service has included several years at tropical stations during the years of peace and inspection of medical services in overseas theaters in the current emergency. In the fall of 1943 he visited Brazil as the official guest of the Brazilian government; following his visit he was decorated in recognition of the assistance that he rendered the medical service of the Brazilian army.

ARMY AWARDS AND COMMENDATIONS

Major John L. Devine Jr.

Major John L. Devine Jr., formerly of Minot, N. D., was recently awarded the Legion of Merit for "exceptionally meritorious conduct in the performance of outstanding service from Sept. 23, 1943 to March 15, 1944." Dr. Devine graduated from Georgetown University School of Medicine, Washington, D. C., in 1937 and entered the service Dec. 12, 1940.

NAVY

NEW EAR PROTECTOR ADOPTED
BY NAVY

A new ear protector, called an ear warden, which guards the wearer against the severe noise shocks of gun blasts and the high noise levels of Diesel and airplane engines, has been officially adopted by the Navy. The warden, made of a special compound of neoprene, aids in eliminating ear discomfort and pain and preventing the partial deafness resulting from long exposure to great noise. The device was developed by the University of California at Los Angeles under the direction of the National Defense Research Committee, Office of Scientific Research and Development. Placed on the allowance lists of the Bureau of Ships and the Bureau of Aeronautics, it is now being produced in small quantities and shipped out to the fleet and to naval installations. Bureau of Ships officials express the hope that manufacturers will reach maximum capacity in about three months.

Known officially as the V-51 (R) NDRC Ear Warden, the new device represents extensive research on prevention of damage to hearing from intense sound. Tests give it an insulation index of 113 against 38 for cotton, heretofore used by the Navy, and indexes ranging from 72 to 106 for other types of ear protectors. Its high insulation index will greatly lessen the hazard of partial and temporary deafness resulting from such continuous loud noises as the roar of airplane and PT boat engines and the constant backdrop of sound in engine rooms. Airplane pilots, for example, will be less likely to suffer the permanent hearing loss which is known to flight surgeons as "aviator's notch." This hearing loss, resulting from continued exposure to engine and other noise, is called a "notch" because it represents a small dip in an individual's hearing chart or audiogram in the region of 4,000 sound cycles per second. Not infrequently, long exposure to noise is a factor in permanent deafness.

While a number of other devices which have been in existence plug the ear canal and reduce the transmission of sound, they are not as well engineered acoustically as the Navy approved model, according to tests made by the Harvard University's Research on Sound Control, under the auspices of the National Defense Research Committee. Experiments were made with ten formulas of the synthetic rubber known as neoprene before the final mix was decided on for the warden. The adopted formula is noninflammable, almost as tough and elastic

as gum rubber, fully as nontoxic and nonirritating, more free from odor, and more resistant to ear-wax, soap and water, and cleaning alcohol. It is also decidedly resistant to sea water. The ear warden also meets other standards set by the Navy. It is easy to insert and remove; it is easy to keep clean; it is comfortable to wear; it is low in cost and feasible to manufacture.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Bothwell Graham III

Lieut. Bothwell Graham III, formerly of Clinton, S. C., was recently awarded a Presidential Unit citation. The presentation was made at Ingram Field, Sampson, N. Y. Dr. Graham, senior medical officer of the Holl Unit dispensary, served as battalion surgeon with the First Marine division in the conquest of the Solomon Islands from Nov. 4, 1942 until Sept. 30, 1943. He entered the Navy on May 26, 1942 and was assigned to the Fifth Defense Battalion, Fleet Marine Force, and in October 1942 participated in the bloodless occupation of the Ellice Islands. He served as assistant battalion surgeon with the Fifth Defense battalion supporting Col. Carlson's Raider's offensive in the eastern landing on Guadalcanal in November 1942 and later served as battalion surgeon with Marine units holding the island of Tulagi. Dr. Graham graduated from the University of Virginia Department of Medicine, Charlottesville, in 1937.

Lieutenant Commander Cyril D. Klaus

Lieut. Comdr. Cyril D. Klaus, formerly of Grand Rapids, Mich., was recently cited by Admiral C. W. Nimitz for his "exceptional devotion to duty on the occasion of his ship receiving a direct hit during an anti-shipping sweep and bombardment. . . . Almost single handedly he administered medical care to nine seriously wounded men. By his skill and professional ability he saved the foot of a petty officer which might otherwise have had to be amputated. During this period he was deprived of the services of his chief pharmacist's mate, who had been seriously wounded. His perseverance and devotion to duty for a long, exhausting period was in keeping with the highest traditions of the naval service." Dr. Klaus graduated from Loyola University School of Medicine, Chicago, in 1932 and entered the service April 1, 1942.

MISCELLANEOUS

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Station Hospital, Scott Field, Illinois: Chemotherapy, Including Sulfonamides and Penicillin, Dr. R. O. Muether, September 8.

Combined Wartime Graduate Medical Meeting and Meeting of the Kentucky State Medical Association, Lexington, Ky.: Chemotherapeutics in Pediatrics, Dr. John A. Toomey; Chemotherapy (Penicillin), civilian medical essayist, Dr. Donald G. Anderson; Symposium (military essayists): Medical Aspects, Brig. Gen. Hugh Morgan; Surgical Aspects, Col. B. N. Carter; Venereal Disease Treatment, Lieut. Col. Thomas Sternberg; Oration in Medicine, Dr. Frederick G. Speidel; Psychosomatic Medicine, Dr. Maurice Levine; Industrial Health Hazards, Col. Anthony Lanza; Present Status of Pain Relief in Labor, Dr. Frederick H. Falls; Cardiovascular Diseases, Dr. William D. Stroud. Evening session: president's address, Dr. Oscar O. Miller; Accelerated Medicine Today and Tomorrow, Dr. Roger I. Lee; Address, Dr. Edward Henry Cary, September 19.

Symposium on Tropical Diseases: Epidemiology, Dr. R. E. Dyer; Medical Aspects of Tropical Diseases, Capt. Alphonse McMahon; New Weapons for Control of Insect Borne Diseases, Brig. Gen. James S. Simmons; Surgical Aspects of the Chronic Dyspepsias, Dr. Irvin Abell; Oration in Surgery, Dr. J. Farra Van Meter; Arthritis, Dr. Ralph Pemberton; Address, Brig.

Gen. Fred W. Rankin; Nutrition—Its Relation to Deficiency Diseases, Col. John D. Youmans, September 20.

At the Station Hospital, Fort Williams, Portland, Maine: Cardiac Neuroses, Cardiac Emergencies, Cardiac Rehabilitation, Drs. Samuel H. Proger and T. Duckett Jones, September 21.

At the Station Hospital, Presque Isle, Maine: The Use of Penicillin and the Sulfu Drugs, Dr. Charles A. Jaueway, September 21.

At the Dispensary, U. S. Naval Construction Training Center, Quoddy Village, Maine: The Pneumonias and Other Respiratory Infections, Dr. Cutting B. Favour, September 21.

At the Station Hospital, Fort Banks, Boston: The Skin, Dr. Francis M. Thurman, September 21.

At the U. S. Naval Hospital, Chelsea, Mass.: Acute Infections of the Central Nervous System, Dr. Derek E. Denny-Brown, September 21.

At the Station Hospital and Lovell General Hospital, Fort Devens, Massachusetts: Stomach, Biliary Tract, Intestinal Disorders, Drs. J. Howard Means, Robert R. Linton and Laurence L. Robbins, September 21.

At the Cushing General Hospital, Framingham, Mass.: Peripheral Vascular Disease, Dr. E. Everett O'Neil, September 21.

At the Station Hospital, Camp Myles Standish, Taunton, Mass.: Contagious Diseases and Complications, Dr. Edwin H. Place, September 21.

At the U. S. Marine Hospital, Brighton, Mass.: Blood Dyscrasias and Transfusions, Dr. Louis K. Diamond, September 21.

At the Station Hospital, Westover Field, Chicopee Falls, Mass.: Pilonidal Sinus and Common Diseases of the Anus and Rectum, Dr. E. Parker Hayden, September 21.

At the Dispensary, U. S. Naval Construction Training Center, Davisville, R. I.: Diarrheal Diseases, Drs. Ralph E. Wheeler and Francis C. McDonald, September 21.

At the U. S. Naval Hospital, Newport, R. I.: Cardiac Neuroses, Cardiac Emergencies, Cardiac Rehabilitation, Drs. Paul D. White and Mandel E. Cohen, September 21.

At the Station Hospital, Bradley Field, Windsor Locks, Conn.: Joint Injuries, Dr. John H. T. Sweet Jr. and associates, September 21.

At the Air Corps Station Hospital, New Haven, Conn.: Fractures of Extremities, Dr. Frank S. Jones, September 21.

At the Deshon General Hospital, Butler, Pa.: Tumors of the Testicle, Capt. Reuben B. Gaines, August 31.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL August 19, page 1147)

INDIANA

Logansport State Hospital, Logansport. Capacity, 2,395; admissions, 821. Dr. C. L. Williams, Superintendent (residents—psychiatry).

KENTUCKY

Norton Memorial Infirmary, Louisville. Capacity, 165; admissions, 4,840. Mr. Arden E. Hardgrove, Superintendent (2 interns, October 1).

MARYLAND

Maryland General Hospital, Baltimore. Capacity, 294; admissions, 5,217. Mr. Stewart B. Crawford, General Superintendent (resident—gynecology and obstetrics).

NEW JERSEY

Perth Amboy General Hospital, Perth Amboy. Capacity, 197; admissions, 4,729. George C. Shicks, Director (2 interns).

NEW YORK

Beth David Hospital, New York City. Capacity, 187; admissions, 3,985. Mr. Harold M. Salkind, Executive Director (6 interns, October 1).

Yonkers General Hospital, Yonkers. Capacity, 180; admissions, 3,646. Mr. C. E. Croft, Superintendent. (2 interns, October 1; 1 intern, January 1).

NORTH CAROLINA

Charlotte Memorial Hospital, Charlotte. Capacity, 325; admissions, 8,145. Mr. Carl I. Flath, Administrator (residents, October 1).

PENNSYLVANIA

Woman's Homeopathic Hospital, Philadelphia. Capacity, 200; admissions, 2,790. Miss Mary A. Smith, R.N., Superintendent (assistant resident).

WEST VIRGINIA

Wheeling Hospital, Wheeling. Capacity, 255; admissions, 4,870. Sister Mary Ruth, Administrator (intern, October 1).

SURVEY PALESTINE'S HEALTH FACILITIES

Word has recently been received of the safe arrival in Palestine of Rear Admiral Charles S. Stephenson of the United States Navy, who flew to that country on a mission for Hadassah, the Women's Zionist Organization of America. Admiral Stephenson, who headed the American Typhus Commission when it toured the Middle East for the United States government last year, was asked by Hadassah to make a survey of its health institutions and services in Palestine and to chart the probable future health needs of that country. Hadassah felt that such a survey was needed immediately in order to lay the groundwork for the vastly expanded health program it contemplates to prepare Palestine to deal with the health needs of the Jewish refugees, who are expected to reach there shortly in large numbers. The work of medical rehabilitation for the Nazi war victims is expected to be so vast and complex as to

require a detailed blueprinting in advance by an expert in the public health field. The large network of medical services in Palestine, both curative and preventive, is directed by Hadassah's representatives in Palestine with funds raised in more than five hundred local chapters throughout the United States.

PUBLIC HEALTH UNDER HITLER

The *Deutsche allgemeine Zeitung* of April 21 (Germany) states that, according to Professor Bockhacker of the Health Office of the DAF, the reduced number of doctors at the beginning of the war made necessary a large scale rationalization of health services. This was made easier by making use of the services of a number of foreign doctors and also by the exceptionally high standard of training of auxiliary medical personnel, especially in spheres in which in peacetime the help rendered by the doctors was more or less mechanical. One measure to intensify the valuable work of the doctor was to reduce private consultations to a minimum by sending the doctor into the factory. It is in the factories in particular that the work of the auxiliary medical staff has been highly effective. They can conduct x-ray examinations and make urine tests without calling on the time of the works doctor. Using these methods has been highly effective. It has been possible to evolve systems under which one doctor can cope with the preliminary work of fifty to sixty assistants.

Bockhacker refutes the widely held opinion that it is possible to assess the working capacity of the worker by means of some onesided examination of output. Experiments of this sort, made among others by the *Wehrmacht*, have meanwhile been abandoned. Psychotechnical methods are never good enough, as they can never fully take the character of the individual into account. In conclusion, Bockhacker declares that war with its hard demands is promoting a natural process of selection. Whereas in the old days social measures helped the weak as well as the strong, today only the strong and the healthy can stand the pace.

According to Zora of March 15, 1944 (Bulgaria) the Chief Public Health Directorate announced that the following new cases of infectious diseases were registered during the week of March 10 to 15: scarlet fever, 44 new cases against 45 for each of the two preceding weeks; diphtheria, 64 new cases against 96 and 85 for the two preceding weeks; typhoid, paratyphoid and dysentery, sporadic cases only; typhus, 73 new cases in twenty-nine inhabited places. Only 6 of them are Bulgarian. Meningitis, 5 cases; infantile paralysis, 1 case. Five or more cases of the same disease were not registered in any single inhabited place.

Le Nouveau Journal of April 3, 1944 (Belgium) states that the Central Office of Statistics published the following figures: During January 1944 there were 10,289 live births: 5,290 boys and 4,999 girls. During the same month there were 12,385 deaths: 6,413 men and 5,972 women.

The *Nieuwe Rotterdamse Courant* of April 1, 1944 (Netherlands) publishes details of population statistics for Rotterdam. On Jan. 1, 1944 the population numbered 614,627, on February 1 612,575, and on March 1 the figures were 604,886.

Donauzeitung, Belgrade, of April 9-10, 1944 (Yugoslavia) publishes a survey of the Croat state spas, mentioning *inter alia* that four hundred springs have so far been discovered but that only forty-two are being utilized.

According to the *Völkischer Beobachter* of April 22, 1944 (Yugoslavia) an epidemic of typhoid (typhus) has broken out among the bandits on the Dalmatian island of Vis. It is continuing to spread, owing to the complete lack of doctors and medicines.

The Rumanian Ministry of Health has concluded an agreement with three Bucharest builders for the construction of a sanatorium for tuberculosis, at a cost of about 300 million lei, according to *Donauzeitung, Belgrade*, of April 2.

ORGANIZATION SECTION

WASHINGTON LETTER

(From a Special Correspondent)

Aug. 21, 1944.

Health Programs for Federal Employees

Hearings opening today on the recently introduced bill providing health programs for employees of the federal government represents the latest step in the campaign led by the Department of Agriculture and other federal officials to establish a universal health project for the civil servant. Specifically the bill, introduced by Representative Jennings Randolph (Democrat, West Virginia), who also was named by House Civil Service Committee Chairman Robert Ramspeck (Democrat, Georgia) to be chairman of the subcommittee holding hearings, provides for an allotment of funds to improve the "physical and mental efficiency" of government employees through a definite health program to be carried out in conjunction with the United States Public Health Service. It would provide free treatment of minor injuries and illnesses, free physical examinations and the elimination of health hazards. Slated to testify are representatives of the American Medical Association, the National Association of Manufacturers, the C. I. O., the A. F. L. and many other groups.

Under the Randolph bill, federal departments and agencies would have authority to establish health programs on recommendation of the Civil Service Commission and the U. S. Public Health Service. Health service would be limited, it is stated, to treatment of minor illness except in case of emergencies or of injury or illness sustained on the job; preemployment and periodic examination; referral of employees to private physicians, and extensive health education programs.

Sponsors estimate that the government has made disbursements of \$8,000,000 annually in payments to federal employees whose health has collapsed completely, forcing retirement before the normal retirement age. They say that a good health program would have kept most of these people in working condition. Backers also say that greater efficiency will be attained by watching the general physical condition of workers. Suggested as an example of a health program in private industry is that of the Standard Oil Company of New Jersey, which provides rigid examinations when employees are hired, health education and safety programs on the job, and continued, periodic check-ups. Top ranking executives get thorough examinations every ninety days. It is said that a great saving of the money invested in all workers in training and experience has resulted through preventing physical breakdown. In the govern-

ment it is said that in one agency illness caused an average loss of 10.2 days per employee and if through a health program this could have been improved by at least three days per employee over 246,000 man-days would have been saved in the year. This would be equivalent to the services of 820 full time employees.

Prominent witnesses on the opening day of the hearing were War Manpower Commission Director Paul V. McNutt, Arthur S. Flemming, Civil Service Commissioner, and Dr. Carl Peterson, Secretary of the Council on Industrial Health of the American Medical Association.

The Epidemic of Poliomyelitis

The epidemic of infantile paralysis in the Eastern Seaboard states, which up to August 21 had taken six lives and had a total of 87 cases under treatment in Washington hospitals, has elicited advice from Dr. Betty Huse of the crippled children's service of the Children's Bureau, United States Department of Labor, that poliomyelitis patients may be safely admitted to the general wards of hospitals. She urged immediate hospitalization when the disease is suspected as a means of getting for the victim expert treatment, which can prevent crippling in many cases. "Fear of the disease often is responsible for an unwillingness by the hospital to admit infantile paralysis cases when only ward accommodations are available," Dr. Huse explained, "and sometimes the general fear in the community is responsible for the hospital's stand. Poliomyelitis cases need not be placed in separate wards, although it may be desirable to do so for ease in handling. It is essential that all precautionary measures be taken, particularly the disinfection of all excretions."

Dr. Huse said that there have been indications of an epidemic condition in New York, North Carolina, Kentucky, Virginia, Pennsylvania, Ohio, Indiana and Michigan, which thus far the Southern states, with the exception of the three named, had escaped. The Mountain and Pacific states, the West North Central states and the New England states are relatively "free" of cases of poliomyelitis.

It was pointed out that the Children's Bureau administers social security funds for the care of crippled children, which are being used for the care of poliomyelitis victims. Funds are available through state agencies and, as a matter of policy, care is given under the crippled children's program to those suffering from poliomyelitis without regard to the parent's ability to pay. In other words, it was said, when poliomyelitis strikes, treatment is given.

WOMAN'S AUXILIARY

Georgia

The Woman's Auxiliary to the Medical Association of Georgia recently completed its twentieth year. At the annual meeting it was reported that 155,563 hours were given to war service by the auxiliary members. Concerted effort in the fight against the Wagner-Murray-Dingell bill was also reported in twenty-six counties.

Iowa

At a meeting of the Sioux Mes-Dames in Sioux City recently the Community Center Committee reported excellent progress made on the new project—the Lanham Nursery for children whose mothers are employed. The government supplied the funds to establish the nursery, and the Sioux Mes-

Dames give their time and provide the "extras" that are needed.

Virginia

The Woman's Auxiliary to the Medical Society of Virginia reported excellent results in its drive for the Leigh-Hodges-Wright Memorial Fund. This fund was established in 1936 for the purpose of supporting an "auxiliary bed" in the state tuberculosis sanatorium for the use of a physician or a member of his family. Since its inception it has been used to assist the daughter of a physician and a medical student who was stricken one month before receiving his degree at the University of Virginia. The fund was named in honor of the members of the State Advisory Council.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

COLORADO

Fellowships in Psychiatry.—The Colorado Psychopathic Hospital, Denver, has been granted funds by the Commonwealth Fund of New York for fellowship training in psychiatry. These fellowships are for a three year period and carry a stipend for each year. The hospital is now taking applications, and those interested should communicate with Dr. Charles A. Rymer, acting director, Colorado Psychopathic Hospital, 4200 East 9th Avenue, Denver.

State Medical Meeting.—The seventy-fourth annual session of the Colorado State Medical Society will be held at the Shirley-Savoy Hotel, Denver, September 27-29, under the presidency of Dr. George P. Lingenfelter, Denver. Among the out of state speakers will be:

Dr. Warren H. Cole, Chicago, Carcinoma of the Colon.
Dr. Fredrick A. Willius, Rochester, Minn., Variables Concerned in Recovery or Death in Acute Coronary Occlusion
Dr. Maxwell M. Wintrobe, Salt Lake City, A Physiologic Approach to Blood Dyscrasias and Their Diagnosis
Dr. Herman L. Kretschmer, President of the American Medical Association, Chicago, Problems in the Management of Infections in the Urinary Tract.

Reuben G. Gustavson, Ph.D., president of the University of Colorado, Boulder, will address the annual banquet Friday on "Place of the Medical School in the Community."

X-Ray Survey Unit Given to State.—On July 18 special ceremonies marked the presentation of Colorado's new chest x-ray survey unit to the state board of health, the acquisition of which completes the first stage of the program recommended by the tuberculosis control committee of the Colorado State Medical Society. The second phase of the program, which was to begin in Denver late in July and in Otero County August 1, is "the employment of photoroentgenographic equipment under the joint auspices of the division of tuberculosis of the state board of health and the Colorado Tuberculosis Association for the purpose of identifying and registering as many as possible of the cases of active progressive tuberculosis in the state of Colorado." While the state medical society has approved the tuberculosis case finding program, the approval of the local county or district medical society will be required before the unit will be operated in any local area.

DELAWARE

State Medical Meeting.—The Medical Society of Delaware will hold its annual meeting in Lewes, September 11-12, under the presidency of Dr. Richard C. Beebe, Lewes. A preliminary program announces the following speakers:

Dr. Stanley Worden, Dover, Tick Fever
Dr. John H. Foulger, Wilmington, Preventive Medicine.
Dr. George J. Boues, Wilmington, Bone Marrow Transfusion.
Dr. John B. Lownes, Philadelphia, Surgical Treatment for Prostatic Obstruction.
Dr. Harrison F. Flippin, Philadelphia, Penicillin Therapy.
Dr. Norris W. Vaux, Philadelphia, Caudal Analgesia
Dr. George H. Gehrmann, Wilmington, Industrial Medicine
Dr. Clayton T. Beecham, Philadelphia, The Early Diagnosis and Management of Gynecologic Cancer

ILLINOIS

Changes in Health Officers.—Dr. Cyrus P. McRaven, Macomb, has been appointed health director of McDonough and Fulton counties, succeeding the late Dr. Edward L. Hill Jr., Mount Sterling.

Chicago

Personal.—Dr. John J. Madden, assistant psychiatrist at the Cook County Psychopathic Hospital, has been named acting superintendent of the hospital during the absence of Dr. Vladimir G. Urse, who has been granted a military leave as superintendent of the hospital.

Searle Plans Expansion Program.—As soon as building restrictions are lifted, G. D. Searle and Company, manufacturer of pharmaceuticals, plans to construct at least one additional building on a recently acquired 5½ acre tract in Skokie which adjoins its present property and on which are located the Searle Research and Manufacturing Laboratories. It is

said that the increased research and manufacturing facilities are necessary in view of the continuing rapid expansion of the firm's business, which the present laboratories, completed in March 1942, can no longer accommodate.

Courses in Hospital Administration.—Five courses in hospital administration will be offered in the first semester at Northwestern University beginning September 20. The courses will be on history and development of hospitals, organization and management of hospitals, professional services to the hospital patient, legal, political and sociological aspects of hospital administration, and fundamentals of medical science. Prospective students may apply for admission as candidates for the degrees of bachelor of science in hospital administration or master of hospital administration or as special students. The course in fundamentals of medical science will be open to students who are not registered for other courses in the program in hospital administration as well as to the regular students. The lecturer in the medical science course, which will be offered for the first time, will be Dr. Theodore R. Van Dellen, associate professor of medicine, Northwestern University Medical School. Scholarships are available to selected candidates through funds provided by the American Hospital Supply Corporation and the Johnson and Johnson Research Foundation.

MICHIGAN

Medical Service Returns Loan to State Society.—On July 23 Michigan Medical Service returned to the Michigan State Medical Society the sum of \$17,544, which was the amount originally advanced by the latter to assist the medical service as organizational expense in 1939-1940.

Upper Peninsula Meeting.—Dr. Edward Sawbridge, Stephenson, was chosen president-elect of the Upper Peninsula Medical Society at its annual meeting in Houghton, July 27, and Dr. Nathan J. Frenn, Bark River, was installed as president. Escanaba was chosen as the place for the 1945 meeting. Among the speakers at the meeting were Drs. Norman F. Miller, Ann Arbor, on "Diagnosis and Management of Cervical Carcinoma"; Edward L. Tuohy, Duluth, Minn., "Differential Diagnosis of Liver Diseases," and Walter C. Alvarez, Rochester, Minn., "Hints in the Recognition of Neuroses."

Appointments at Michigan.—Dr. James L. Wilson, professor of pediatrics, New York University College of Medicine, has been appointed professor and chairman of the department of pediatrics and communicable diseases at the University of Michigan Medical School, Ann Arbor, effective October 15, and Dr. William Dodd Robinson, formerly of Vanderbilt University School of Medicine, Nashville, Tenn., has been appointed assistant professor in the department of internal medicine and director of the Rackham Arthritis Research Unit, effective September 1. Gordon K. Moe, Ph.D., instructor in pharmacology, Harvard Medical School, Boston, has been named assistant professor in the department of pharmacology, effective August 1.

Changes in Health Officers.—Dr. Clement E. Lockwood, Holly, has been appointed director of the Altery-Schoolcraft District Health Department, succeeding Dr. Henry H. Asher, who died recently.—Dr. Robert E. Flood, Northport, has been appointed health officer of St. Joseph County, succeeding Dr. Frederick A. Musachio (THE JOURNAL, May 20, p. 220), who resigned to accept a similar position in Texas.—Dr. Sidney I. Franklin, Newberry, has resigned as director of the Luce-Mackinac County Board of Health.—Dr. Willard G. Beattie has been named health officer of Ferndale.—Dr. Leonard C. Bate, Stambaugh, has resigned as director of the Iron-Ontonagon County Health Department, effective August 15, to enter private industrial practice.—Dr. Neal J. McCann has resigned as health officer of Ishpeming.—Dr. Hugh B. Robins has been appointed health officer of the city-county health department in Battle Creek. Dr. Awra A. Hoyt, who served as health officer of Battle Creek for twenty-four years, resigned recently.

NEW JERSEY

New Officers of State Health Board.—Dr. Martin H. Collier, Grenloch, was elected president of the New Jersey State Department of Health at a meeting in Trenton, July 11. Clarence J. Schweikhardt, D.D.S., Maplewood, is vice president. New members of the board are Dr. Frederick P. Lee, Paterson, and Mr. Thomas L. Lawrence, Hamburg.

Personal.—Robert P. Fischelis, Se.D., has resigned as secretary of the New Jersey Board of Pharmacy, a position he has held since 1926, to devote full time to his work as chief chemist of the drugs and health supplies branch, office of

civilian requirements of the War Production Board, Washington, D. C. Temporarily he will continue to live in Trenton and will continue to serve as president of the New Jersey Pharmaceutical Association. Mr. Adolph V. Palumbo, a member of the state board of pharmacy since 1938, will succeed Dr. Fischelis as secretary of the board.

NEW YORK

Stockton Kimball Named Assistant Dean at Buffalo.—Dr. Stockton Kimball, associate in medicine and pharmacology at the University of Buffalo School of Medicine, Buffalo, on July 15 was appointed assistant dean of the school. Dr. Kimball graduated at the University of Buffalo in 1929 and has been for the past seven years a member of its faculty.

Personal.—Dr. Edith Gardner Mead, member of the Poughkeepsie Board of Health, has been appointed full time medical supervisor of the Poughkeepsie school system to succeed Dr. Helen L. Palliser, whose resignation will become effective on October 1. Dr. Palliser served on a part time basis.—Dr. Herman G. Weiskotten, Syracuse, on July 25 was reappointed a member of the Public Health Council for a term of six years. Dr. Weiskotten, who is dean of the Syracuse University College of Medicine, has been a member of the council since 1936.

New York City

Dr. Moorhead Delays Retirement.—Dr. John J. Moorhead, who was to retire August 1 as medical director of the New York City Transit System, has consented to continue in the position for another year at the request of the board of transportation.

New Department of Medical Films.—A new department of medical films is now available in the New York University Film Library under the supervision of a committee of the New York University College of Medicine. Distribution of the films will be restricted to professional groups and organizations. A series of motion picture films on neuropsychiatric disorders is available to medical and strictly scientific groups for educational purposes by the new department. The films are the work of Dr. S. Philip Goodhart, chief of the neuropsychiatric division, Montefiore Hospital for Chronic Diseases, and professor of clinical neurology, Columbia University College of Physicians and Surgeons; and Major Benjamin H. Balser, M. C. The films have been used for a number of years in courses given to medical students at Columbia and are now made available for teaching purposes and professional discussion groups through the medical department of the New York University Film Library.

Academy of Medicine to Define "Fee Splitting" and "Rebating."—On August 2 the council of the New York Academy of Medicine voted to amend its constitution and by-laws to define more fully the terms "fee splitting" and "rebating" and voted to require applicants for membership to sign the following pledge: "The undersigned hereby agrees to accept the council of the academy as the sole and only judge of his qualifications to remain a fellow." The action is an aftermath of the recent Moreland investigation into "fee splitting" and "rebating" among physicians treating workmen's compensation claimants, which resulted in a number of physicians having their privileges to treat these cases revoked. The academy is reported to have admonished a group of its fellows who were implicated in the charges. In an announcement to the press the academy is reported to have said "The practices referred to are, in the opinion of the academy, entirely contrary to the Hippocratic Oath taken by every physician on receipt of his medical degree; without his signed pledge to avoid such practices no candidate for fellowship can be considered by the academy; and on proof of guilt in such matters, a member is subject to suspension or expulsion from fellowship."

Graduate Courses.—Forty-seven part time courses in widely different branches of medicine, and five full time one week courses will be given for postgraduate physicians by the Mount Sinai Hospital in affiliation with the Columbia University College of Physicians and Surgeons. The courses will begin on September 25 and will be taught by members of the attending staff of Mount Sinai as part of the program of postgraduate medical education of Columbia University. Stress is laid in teaching on diagnosis, treatment and important technical procedures, and courses will include operative demonstrations, clinical conferences and ward rounds as well as lectures. Among the subjects covered in the fall curriculum will be allergy, anesthesia, cardiovascular diseases, electro-

cardiography, fluoroscopy, gastroenterology, gastroscopy, hematology, diseases of the kidneys and arteries, neurology, electroencephalography, ophthalmology, orthopedics, otology, pediatrics, physical therapy, proctology and tropical medicine. A second series of courses will begin on Feb. 5, 1945. The courses are not intended to train physicians to become specialists but will of interest to physicians who wish to train in laboratory methods as well as bedside instruction. The courses are divided into two groups, those open to all general practitioners and those open only to physicians who have had adequate preliminary training and experience in a related specialty. Application should be made to the Secretary for Medical Instruction, Mount Sinai Hospital, 100th Street and 5th Avenue, New York 29.

OREGON

University News.—Dr. Kenneth C. Swan, research associate in ophthalmology, State University of Iowa College of Medicine, Iowa City, has been appointed associate professor of ophthalmology at the University of Oregon Medical School, Portland.—Dr. L. Everard Napier, director of the Calcutta School of Tropical Medicine in India, lectured at the University of Oregon Medical School July 15 and 17. At the invitation of the National Research Council and under the auspices of the John and Mary R. Markle Foundation, Dr. Napier has been lecturing throughout the country on tropical diseases.

State Medical Meeting.—The Oregon State Medical Society will hold its seventieth annual session at the University of Oregon Medical School, Portland, September 2-3, under the presidency of Dr. Thompson Coberth, The Dalles. The preliminary program includes the following speakers:

Comdr. Jacob J. Enkelis (MC), (subject not announced).
Major George W. Waters, M. C., Fractures of the Elbow Joint.
Capt. Scott H. Goodnight, M. C., Clinical Notes on Malaria.
Capt. Milton Mendlowitz, M. C., Strain of the Pectoralis Minor Muscle as a Cause of Precordial Pain.
Dr. Charles D. Donahue, Eugene, Use of Stilbestrol in Carcinoma of the Prostate.
Dr. Edwin E. Osgood, Portland, Clinical Use of Penicillin.
Dr. John E. Raaf, Portland, Care of the Patient with Acute Spinal Cord Injury.
Dr. Eugene W. Rockey, Portland, Care of Colostomies.
Dr. Raymond R. Staub, Portland, Brucellosis.
Dr. James D. Stewart, Eugene, Subtrochanteric Osteotomy for Non-union of Hip Fracture.

One of the features of the meeting will be a symposium on "Medical Problems Arising Under the Workmen's Compensation Law and the Occupational Disease Law" by Dr. Douglas G. Cooper, assistant medical director, and Mr. F. I. Brown, claims supervisor, Oregon State Industrial Accident Commission, Salem.

PENNSYLVANIA

State Medical Meeting.—The ninety-fourth annual session of the Medical Society of the State of Pennsylvania will be held at the Hotel William Penn, Pittsburgh, September 19-21, under the presidency of Dr. Augustus S. Kech, Altoona. Included among the guest speakers will be:

Dr. Clyde L. Deming, New Haven, Conn., Acute and Chronic Symptoms and Diagnosis of Movable Kidney; Conservative and Radical Treatment.
Dr. James P. Leake, Bethesda, Md., The Control of Communicable Diseases.
Dr. Emil Novak, Baltimore, Some Misconceptions and Abuses in Gynecologic Organotherapy.
Dr. Ramon Castroviejo, New York, Indications for Keratoplasty and Keratetectomies, with Kodachrome Lantern Slides and Motion Pictures.
Dr. Herman E. Pearce Jr., Rochester, N. Y., The Avoidance of Difficulty in Biliary Surgery.
Dr. Earl W. Netherton, Cleveland, Eczema—Management and General Considerations.
Dr. Alexander S. Wiener, New York, Rh Factors and Their Application in Clinical and Legal Medicine.
Dr. Clayton W. Greene, Buffalo, Certain Unusual Clinical Pictures in Renal Disease.

The program also includes a number of Pennsylvania physicians. One feature of the meeting will be a panel discussion on clinical endocrinology by Dr. Edward H. Rynearson, Rochester, Minn., Dr. Charles W. Dunn, Philadelphia, and Dr. Novak.

Philadelphia

Clinics for Early Diagnosis of Cancer.—The International Cancer Research Foundation has established five clinics in Philadelphia to afford periodic physical examinations to discover early symptoms of cancer. Emphasis is placed on prevention of the disease, and the clinics are for both men and women. The clinics are located at the Temple University Hospital, Woman's Medical College of Philadelphia, Jefferson Medical College, Hospital of the University of Pennsylvania, and Hahnemann Hospital, according to the Temple University News Letter.

UTAH

Appointments at Utah.—Dr. Francis D. Gunn, associate professor of pathology, Northwestern University Medical School, Chicago, has been appointed professor and head of the department of pathology at the University of Utah School of Medicine, Salt Lake City, effective September 1, according to the *Deseret News*, July 15. Dr. Charles E. McLennan, assistant professor of obstetrics and gynecology, University of Minnesota Medical School, Minneapolis, has been appointed professor and head of the department of obstetrics and gynecology at the University of Utah. Plans were also announced to construct an animal laboratory building. The graduation of the first fourth year class at the medical school will be held September 12.

WISCONSIN

State Medical Meeting in Milwaukee.—The one hundred and third annual session of the State Medical Society of Wisconsin will be held in Milwaukee, September 18-20, under the presidency of Dr. Russell M. Kurten, Racine. A preliminary program lists the following out of state speakers, among others:

- Dr. Wallace E. Herrell, Rochester, Minn., Penicillin Therapy.
Dr. James G. Carr, Chicago, Cardiac Traumatism.
Dr. Curtis J. Lund, Minneapolis, Nutrition in Pregnancy.
Dr. Sumner L. S. Koel, Chicago, Treatment of Burns.
Dr. T. Duckett Jones, Boston, Prevention and Treatment of Rheumatic Fever.
Dr. William A. Thomas, Chicago, Histoplasmosis with Diagnosis Made from Multiple Cutaneous Lesions.
Dr. Owen H. Wangenstein, Minneapolis, Ulcer Problem.
Dr. Emil D. W. Hauser, Chicago, Low Back Pain Due to Functional Decompensation of the Back.
Dr. Samuel W. Donaldson, Ann Arbor, Mich., Professional Bureau of the College of Radiology and Its Relationship to Hospitals.
Dr. Edward A. Oliver, Chicago, The Eczematous Dermatoses.
Dr. Loyal Davis, Chicago, Surgery in the Soviet Union.
Dr. Morris Fishbein, Editor of *THE JOURNAL*, Chicago, Postwar Planning for Medical Services.
Dr. Newell C. Gilbert, Chicago, Physiologic Conditions to Be Considered in Coronary Heart Disease.
Dr. Bayard T. Horton, Rochester, Clinical Use of Histamine.
Dr. M. Edward Davis, Chicago, Modern Management of the Third Stage of Labor and Its Complications.
Dr. Henry L. Williams, Rochester, Chemotherapy in Otolaryngology.
Dr. Avery D. Prangen, Rochester, Surgical Treatment of the Extraocular Muscles—Some Suggestions.
Lieut. Col. James E. Ash, M. C., curator, Army Medical Museum, Washington, D. C., Epibulbar Tumors.
Dr. John A. Toomey, Cleveland, Present Status of the Early Treatment of Poliomyelitis.
Lieut. Comdr. James P. Conway (MC), A Study of the Spread of Streptococcal Disease.

On Tuesday morning, September 19, Dr. Winfred Overholser, professor of psychiatry, George Washington University School of Medicine, Washington, D. C., will deliver the Theresa Lemberg Rogers Memorial Lecture on "Psychiatric Problems in the Aged." Obstetric manikin demonstrations will be conducted by Drs. Davis, Lawrence M. Randall, Rochester, and Russell J. Moe, Duluth. Other features during the meeting will include round table luncheons, the secretaries' conference and motion pictures. Entertainment will be provided at the smoker by Drs. Leander J. VanHecke, Milwaukee, and Emmett T. Ackerman, Muscoda, and his wife.

GENERAL

Mary Beard Resigns from Red Cross.—Miss Mary Beard for a number of years director of the American Red Cross nursing service, has resigned for reasons of health. Her successor is Miss Virginia M. Dunbar, who has been serving as deputy to Miss Beard.

Special Society Elections.—Dr. Clarence G. Salisbury, medical director of Sage Memorial Hospital, Ganado, Ariz., was chosen president-elect of the Association of Western Hospitals at its annual meeting in San Francisco July 5 and Dr. Fred O. Butler, medical director of Sonoma State Home, Eldridge, Calif., was installed as president. Other officers include Mr. Gordon W. Gilbert, administrator of St. Luke's Hospital, Spokane, Wash., and Dr. John C. Sharp, medical director of Monterey County Hospital, Salinas, Calif., vice presidents, and Mr. George U. Wood, superintendent of Peralta Hospital, Oakland, Calif., treasurer.—Dr. Wingate M. Johnson, Winston-Salem, N. C., was elected president of the American Geriatrics Society at its annual session held in New York, June 8-10, and Drs. Walter E. Vest, Huntington, W. Va., and Edward B. Allen, White Plains, N. Y., were chosen vice presidents. Dr. Malford W. Thewlis, Wakefield, R. I., is the secretary and Dr. Richard J. Kraemer, Wickford, R. I., treasurer. The next meeting will be held in New York, June 7-9, 1945.

Contest for Hospital Design.—The Modern Hospital Publishing Company offers six awards in each of two competitions, one for the best designs for a small general hospital and two for the best designs for a small community health center. The competitions are open to any architect, architectural student or draftsman, excepting only those regularly employed by the professional adviser or by the firms or organizations of the judges. Two or more architects or an architect and a hospital administrator, consultant or health officer may work as a team. The first award in both competitions will consist of \$1,000. The other awards are \$750, \$500 and three of \$100. The competition is offered to encourage the building, in areas where they are needed, of small hospitals that are efficiently arranged, suitable for smaller communities, creditable in architecture, simple in design, in good taste, economical to build, to operate and to expand and that make maximum use of the best ideas in planning and construction; to furnish to the trustees of small hospitals ideas that will stimulate them to provide better accommodations, and to encourage architects to give more attention to the designing of good small hospitals and community health centers. The judges are Dr. Malcolm T. MacEachern, associate director, American College of Surgeons; Graham Davis, hospital consultant, W. K. Kellogg Foundation, Battle Creek, Mich.; Dr. Vane M. Hoge, chief, hospital facilities section, U. S. Public Health Service; Mies van der Rohe, professor of architecture, Illinois Institute of Technology, Chicago; Nathaniel A. Owings, Chicago; Henry Shepley, Boston, and Charles Butler, New York, all architects. Additional details may be addressed to the Modern Hospital Publishing Company, Inc., 919 North Michigan Avenue, Chicago 11.

Academy of Neurological Surgery.—The seventh annual meeting of the American Academy of Neurological Surgery will be held at the Ashford General Hospital, White Sulphur Springs, W. Va., September 7-9, under the presidency of Dr. A. Earl Walker, Chicago, whose address will be on "Neurological Surgery at the Crossroads." Among other speakers will be:

- Capt. Major H. Harris and Major George L. Maltby, M. C., Preliminary Analysis of Lumbar Sympathectomy in the Treatment of Trench Feet.
Lieut. Col. Daniel C. Elkin, M. C., Vascular Injuries.
Major Robert P. Kelly, Jr., M. C., Split Thickness Grafts in the Treatment of Osteomyelitis.
Capt. William C. Ward and Lieut. Frank F. Allbritten Jr., M. C., Presentation of Problems in Peripheral Nerve Surgery.
Dr. Edwin B. Boldrey, San Francisco, Stainless Steel Wire Mesh in the Repair of Skull Defects.
Major M. Barnes Woodhall, M. C., The Fate of Whole Fresh Homogenous Nerve Grafts in Men with Remarks Concerning Frozen Dried Nerve Grafts.
Drs. Arthur R. Elvidge and Hamilton A. Baxter, Montreal, Que., A Modification of the Roger Anderson Splint for Severe Fractures of the Facial Bones Associated with Cranial Fractures.
Col. William J. Bleckwenn, M. C., Observations on Neurosurgery and Neuropsychiatry in the South Pacific Theater.
Drs. Joseph P. Evans and Mark I. Scheinker, Cincinnati, Histologic Studies of the Brain Following Head Trauma and Decerebrate Rigidity Following Head Injury.
Drs. Theodore C. Erickson and Henry M. Suekle, Madison, Wis., Observation on the Scalenus Anticus Syndrome in War Workers.
Lieut. Col. David L. Reeves, M. C., Primary Chronic Coccidioidal Meningitis.
Major George A. Baker, M. C., Eosinophilic Granuloma of the Skull.
Dr. Wallace B. Hamby, Buffalo, Tumors of the Spinal Canal in Childhood.
Lieut. Robert H. Pudenz and Lieut. C. Hunter Shelden, M. C., Ventriculocisternostomy: Report of Four Cases.

On Saturday morning there will be a tour of the hospital and ward rounds with the medical staff of the Ashford General Hospital.

Aero Medical Association.—The sixteenth annual meeting of the Aero Medical Association of the United States will be held at the Jefferson Hotel, St. Louis, September 4-6. Among the speakers will be:

- Dr. William R. Stovall, Washington, D. C., Physical Requirements and the Private Flier.
Dr. Wilbur F. Smith, Indianapolis, Impressions of a Field Examiner on Entering the Washington Office.
Malcolm Y. McCormick, M. A., Washington, D. C., Physical Competency and Performance.
Dr. Louis B. Flexner, Baltimore, The National Research Council's Advisory Committee on Civilian Aviation Medicine.
Dr. Alvan I. Barach, New York, Development of Pulmonary Active Tuberculosis as the Result of Aeroembolism at Simulated Altitude Above 40,000 Feet.
Dr. Meyer H. Halperin, Ross A. McFarland, Ph.D., and J. I. Niven, Ph.D., Boston, Alteration in the Effects of Altitude on Vision by Glucose and Carbon Monoxide.
Dr. Thomas H. Sutherland, Marion, Ohio, The Legal Basis of Medical Safety in Aviation.
Drs. Henry F. Helmholz Jr., J. B. Bateman and Walter M. Boothby, Rochester, Minn., Studies in High Altitude Physiology.
Drs. Charles F. Code, Earl H. Wool and Edward H. Lambert and Edward J. Baldes, Ph.D., Rochester, Studies on the Physiology of Acceleration.
Dr. William R. Rowland, Randolph Field, Texas, Night Blindness in Flying Personnel—Observations on Patients: Studies at the A. A. F. School of Aviation Medicine.

Comdr. Ashton Graybiel (MC) and Lieut. W. B. Clark H-V(S), Pensacola, Fla., Disorientation in Pilots.
 Lieut. Joseph L. Lilienthal Jr. (MC), Pensacola, The Use of Hyoscine in Air Sickness.
 Lieut. Col. F. G. Hall, A. C., Dayton, Ohio, Physiologic Adjustments to High Altitudes.
 Lieut. Col. A. P. Gage, A. C., Dayton, Pressure Breathing.
 Lieut. Max David Steer, H-V(S), Pensacola, Improvement of Voice Communication in Flight.
 Capt. S. R. M. Reynolds, M. C., and Capt. H. Dohrman, M. C., Orlando, Fla., The Role of the Personal Equipment Officer in the A. A. F.
 Lieut. Comdr. Kenneth S. Scott (MC) and Lieut. Comdr. Marion T. Martin (MC), Pensacola, Aviation Safety.
 Major George H. Hass, M. C., Randolph Field, Relation Between Force, Major Injuries and Aircraft Structure with Suggestions for Safety in Design of Aircraft.
 Col. Manford S. White, M. C., Orlando, Medical Training at the A. A. F. School of Applied Tactics.
 Lieut. Richard A. Howard, Orlando, Survival Off the Land.
 Dr. George R. Harris, Pittsburgh, Physical Fitness.

Incidence of Poliomyelitis.—In the first thirty-one weeks of 1944 the United States has had more cases of infantile paralysis reported than at any comparable time shown on the records in twenty-eight years. The National Foundation for Infantile Paralysis announces. Latest figures from the U. S. Public Health Service, showing state reports through August 5, reveal a total of 3,992 cases, the National Foundation said. This is 1,226 cases more than reported for the same period last year, when the nation suffered its third worst poliomyelitis epidemic, and 1,089 cases more than in 1931, when the second worst outbreak was recorded. The records of the worst outbreak in 1916 show there were 6,767 cases by August 1 of that year. In five states where the outbreaks are in epidemic or near epidemic proportions, the total cases reported through Aug. 5, 1944 are higher than those states reported for the entire year of 1943. They are:

State	Through Aug. 5, 1944	Entire Year of 1943
New York	902	692
North Carolina	470	37
Kentucky	377	157
Pennsylvania	284	143
Virginia	205	61

The serious or threatening outbreaks this summer are confined almost entirely to states east of the Mississippi, while last year's were largely west of the river.

States which last year had high rates are now nearly normal:

State	Through Aug. 5, 1944	Comparable Period of 1943
California	196	842
Oklahoma	30	240
Kansas	36	109
Texas	116	685

Mr. Basil O'Connor, president, reported that the National Foundation has sent epidemic aid, either in emergency funds, professional personnel or supplies and equipment, into thirteen affected states. In addition to the five named they are Ohio, Tennessee, Michigan, Mississippi, Indiana, Washington, Oregon and California. Outbreaks in the latter three states earlier this year have now waned.

Dr. Bachmeyer Directs Hospital Service.—Dr. Arthur C. Bachmeyer, director of hospitals of the University of Chicago and associate dean of the university's Division of Biological Sciences, on August 1 was chosen director of study in the two year program to survey American Hospitals and their postwar expansion needs. A recently appointed commission, of which Thomas S. Gates, LL.D., president of the University of Pennsylvania, Philadelphia, is chairman, will carry out the study, which will be financed by a grant of \$35,000 each by the Commonwealth Fund of New York, the National Foundation for Infantile Paralysis and the W. K. Kellogg Foundation. The American Hospital Association will make an additional contribution of \$15,000 if it becomes necessary. It is hoped that the study will determine the adequacy of distribution of present hospital facilities and the best method for ensuring adequate hospital care and such facilities to all citizens. Members of the committee include:

Charles P. Cooper, New York, president, Presbyterian Hospital, first vice president, American Telephone and Telegraph Company.
 Katharine J. Denford, R.N., Minneapolis, director, School of Nursing, University of Minnesota.
 Albert W. Dent, New Orleans, president, Dillard University (Flint Goodridge Hospital).
 Rt. Rev. Msgr. Thomas O'Dwyer, Los Angeles, director of Catholic Charities, Archdiocese of Los Angeles.
 Clinton Golden, Pittsburgh, assistant to the president, United Steelworkers of America.
 Dr. Everts A. Graham, St. Louis, surgeon, past president, American College of Surgeons.
 Dr. Wilson L. Halverson, Sacramento, commissioner of health of California.
 Herbert Hoover, Stanford University, Calif., trustee, Stanford University (Stanford University Hospital).
 Ada Belle McCleery, R.N., Stepping Stone, Geneva, Ill., former superintendent, Evanston Hospital, Ill.
 Dr. Leroy M. S. Miner, Boston, professor of clinical oral surgery and dean, Harvard University Dental School, Boston.

Dr. Claude W. Munger, New York, medical director, St. Luke's Hospital.

Clarence Poe, LL.D., Raleigh, N. C., editor, the *Progressive Farmer*.
 Dr. Willard C. Rappleye, New York, dean, Columbia University College of Physicians and Surgeons.

Edward L. Ryerson Jr., Chicago, trustee, University of Chicago (University of Chicago Clinics), chairman of the board, Inland Steel Company.
 J. Barrye Hall, Farnville, Va., president, Southside Community Hospital.

Frank J. Walter, Denver, administrator, St. Lukes Hospital.
 Matthew Woll, Washington, D. C., vice president, American Federation of Labor.

LATIN AMERICA

Health Activities in Latin America.—*Institute of Legal Medicine.*—The Faculty of Medical Sciences of the Central University of Ecuador announces the creation of a permanent Institute of Legal Medicine in connection with the university. Dr. José Cruz Cueva, Pichincha No. 24, Quito, Ecuador, has been appointed secretary of the institute, the objectives of which are to disseminate knowledge in the field of legal medicine, the improvement of its teaching in the universities, scientific investigation and research to furnish a basis for the greater understanding and solution of medicolegal problems in Ecuador, technical cooperation with all agencies and officials engaged in the administration of justice, and the technical reform of the laws dealing with medicolegal problems. Life members of the institute will include the dean of the faculty of medical sciences and the professors of legal medicine, psychiatry, histology and pathologic anatomy, criminology and penal law and toxicology of the Central University of Ecuador.

Hospital News.—A 300 bed hospital is planned in La Paz at a cost of about one million dollars. It will be open only to workmen and their families. The project will be directed by the Caja de Seguro y Ahorro Obrero, the Workmen Health Security Institution and Savings Bank. The town has one larger hospital having accommodations of about 550 beds.

Society News.—According to *Medica*, the second National Congress of Cancer will be held early in March 1945 in Havana under the auspices of the Cuban Society of Cancer. It is planned to open to the public for the first time during the congress the dispensary of the League Against Cancer.—Dr. Oseas Sampaio was chosen president of the Associação Piauiense de Medicina, Piahy, Brazil, recently.

Puerto Rico's Proposed Medical School.—A 600 bed hospital and ten other buildings to be spread over 30 acres of land are included in the general plans for the proposed medical school in Puerto Rico to be established under the auspices of the University of Puerto Rico, San Juan, with an allotment of \$500,000 granted by local law to organize the school. The complete cost of the project will ultimately be \$4,500,000. It is planned to have a contagious disease hospital in a four story building providing 100 beds; a cancer hospital of the same size, already approved by the Insular Health Department; an ophthalmic institute of the same size; a service building with an electric plant, laundry and other services; a blood bank and other laboratories; a kennel for animals used in experiments; a pharmacy and dentistry school; class room units; a dormitory for nurses; a dormitory and cafeteria for 200 students; a psychiatric hospital, and a school for obstetrics. There would also be recreation facilities. The school would graduate fifty doctors each year.

Health Program in Trinidad.—Two million dollars will be expended in Trinidad in the coming year for the expansion of health services which include the creation of three health centers, in addition to two already in operation, the establishment of twelve rural dispensaries, an educational health campaign, improvement in the Trinidad Leprosarium, employment of additional specialists for hospitals, higher salaries for nurses, and appointment of an officer to supervise hygienic instructions in schools and colleges. Work on the construction of a tuberculosis sanatorium, deferred because of war priorities on building materials, is to begin soon; the anticipated cost will be \$1,500,000. As a part of the general program to improve health standards in the British West Indies, courses in hygiene and sanitation in all scholastic curriculums will be included. Plans are also under way to establish a laboratory designed for the research in nutritional problems in the West Indies.

CORRECTION

Antibacterial Action of Penicillin.—In the article on penicillin by Herrell et al., *THE JOURNAL*, August 12, page 1004, in the column headed "Susceptible Organisms," table 1, the term "Vibrio comma" should be "Clostridium septicum." The term "Vibrio comma" should appear at the bottom of the column headed "Insusceptible Organisms."

Prevention of Fires and Explosions in Operating Theaters

Accidents due to the ignition and explosion of anesthetic vapors led to the setting up of a committee of the Institution of Electrical Engineers to consider the electrical conditions in operating rooms and to design equipment for the elimination of explosives. The cooperation of the Medical Research Council, the British Standards Institution, the Surgical Instrument Manufacturers Association and leading surgeons was obtained and resulted in the formation of the Operating Theaters Electrical Apparatus Committee. During the early part of the war the work was in abeyance, but the prevalence of fatal explosions has led to recommendations which have now been accepted by the Ministry of Health and sent to all hospitals in the form of a warning notice to be posted in operating theaters and anesthetic rooms. The notice states that accidents are usually due to (1) ignition of anesthetic vapor by cautery, surgical diathermy, electrical switches or similar appliances; (2) overheating, short circuiting or breakage of the small electric bulbs, or their conducting wires or leads, used in various forms of endoscopy; (3) generation of static electricity resulting in trolleys, tables, blankets and even the clothing of operating personnel becoming charged with electricity. (Contact with an object of a different electrical potential may produce a spark which ignites an anesthetic vapor. The use of alcohol for cleansing the patient's skin involves similar danger.)

In describing the recommended precautions, the committee points out that hot wire cauteries and surgical diathermy present possibilities of ignition, especially near the patient's face. There is also some danger attending the use of x-ray apparatus, motor driven suction apparatus and electrical equipment for lighting, heating and sterilizing, unless it is kept away from the patient. At least five minutes before any form of cautery or diathermy is to be used, all ignitable anesthetics, such as ether, ethylene, ethyl chloride or cyclopropane, must be removed from the apparatus and a safe agent must be substituted. A simple precaution is to blow air or some safe gas through the anesthetic apparatus before use when diathermy is projected, even under a nonignitable anesthetic. It is not sufficient to turn off the ether tap, as this may not be gas tight. The ether bottle should be removed, and if it must be replaced it should first be rinsed out. The presence of oxygen and/or nitrous oxide, although these are not ignitable, increases the risk of ignition of other gases. Surgical lamps are often used with some form of regulating resistor. These are usually made for 2.5 or 3.5 volts. It may be dangerous to increase the voltage beyond this to meet the surgeon's request for more light. All insulated flexible wire connected with surgical lamps should be inspected and renewed. If this is not done, the insulation may become faulty or some of the wire strands may be broken, although the lamp appears to function normally. Technical advice should be obtained on methods to limit the current and voltage to values which greatly reduce the risk of ignition even if a short circuit occurs. Foot switches should be flame proof. Insulated apparatus, such as rubber tired trolleys, can be electrified in various ways—for instance, by drawing a dry blanket or towel across them. All anesthetic and operating instrument tables and all

trolleys, if insulated by nonconducting rubber tires, must be fitted with trailing chains which make good contact with the floor. This method is useless when the floor is covered with dry, nonconducting rubber, cork carpet or linoleum. Anesthetists and others should remember that under suitable conditions they themselves may become charged by their own movements, and shoes incorporating "conducting rubber" may be used as a safeguard on conducting floors. The general use of this rubber for tubing and tires would tend to prevent accidents. Under war conditions, it is pointed out, dampening of the floor may have to be adopted instead. The generation of static charges is facilitated by a dry atmosphere. Hence the danger is greater in time of high barometric pressure. Some security may be obtained by slightly dampening face pieces, bags, tubing and floors. If it is necessary to make or unmake metallic unions or carry out similar alterations on anesthetic equipment, all ignitable gases must first be cut off.

Diethylstilbestrol in Cancer of the Breast

At the Section of Radiology of the Royal Society of Medicine the treatment of about 100 cases of advanced cancer of the breast with diethylstilbestrol was discussed. Dr. Frank Ellis said that correspondents in the *British Medical Journal* had drawn attention to this treatment and some radiotherapists therefore decided to try it. Cases of advanced carcinoma of the breast often came for radiotherapy, they reasoned, and if a more effective treatment could be found it was important to know it. Owing to the short period of observation, only preliminary reports could be collected. He described 31 cases, in all of which except 1 the effects of diethylstilbestrol could be noted without any complicating effects of radiation. Some were too advanced for radiotherapy; others were on the waiting list for it; and still others had passed the stage when further irradiation could be useful. The doses of diethylstilbestrol were relatively large unless the patients were intolerant. The average was 15 mg. daily. In some cases, but in none which showed improvement, the administration was followed by nausea and vomiting. Other manifestations were activity of the breasts, with pigmentation, tenderness of the areola and in some cases resumption of menstruation. Eight patients showed improvement; their average age was 67.6 years. Fifteen, with an average age of 53.5 years, became worse under treatment. Two became worse during the administration but improved, both subjectively and objectively, after it was stopped. His conclusion was that diethylstilbestrol might make the malignant condition of a younger woman worse but might have value for an older woman. It produced no improvement in bone metastasis.

Dr. S. B. Adams said that of 10 patients 4 showed improvement, 1 being a woman aged 82. In 3 cases the lesions grew in size during the treatment, though the main lesion shrank. In the first case treatment began in July 1943. Only 1 mg. of diethylstilbestrol was given daily. There was definite improvement. There was originally a deep cancer crater of the breast with diffuse infiltration of the chest wall and skin involvement. This healed, leaving a fibrous scar with two small residual nodules. The liver had enlarged since the treatment started, he said, though whether or not this was due to secondary deposits could not yet be stated.

Dr. Alexander Haddow described 13 cases, several of which had been previously treated surgically or by high voltage x-rays and had shown recurrence. Diethylstilbestrol was given in total doses varying from 75 to 676 mg. over periods of from four to twenty-four weeks. Administration was by mouth or intramuscular injection, sometimes by both. In cases responding to the treatment red lesions tended to show a purplish tinge or pallor. Small skin nodules were flattened and

occasionally disappeared. Larger nodules and masses might undergo partial regression. In these 13 cases there was continued advance of the disease in 9, temporary improvement in 3 and definite and more lasting benefit in 1. Favorable advances were much more likely in the older women, this series also demonstrated.

In the whole series recorded by various observers there were 69 patients under the age of 58, of whom 43 did not improve and none showed spectacular improvement. Of 52 over the age of 58 at least 17 improved and 6 or 7 showed spectacular improvement, amounting in some to complete disappearance of advanced disease. Prof. E. C. Dodds said that in patients over 50 it was important to determine the general systemic effect of estrogen therapy because treatment of disorders of the menopause with synthetic estrogens showed great physical and psychologic effects, and these were likely to influence the general condition of the patient with carcinoma. Professor Dodds expressed surprise at the smallness of the dosage reported by some of the observers. It seemed to him that it would have been worth while to give massive doses, he said, and he was also surprised that more powerful synthetic estrogens than diethylstilbestrol were not tried.

BRAZIL

(From Our Regular Correspondent)

July 8, 1944.

Rabies in Rio de Janeiro

At the last meeting of the Brazilian Society of Hygiene, Dr. J. P. Fontenelle, professor of public health and director of the Division of Health Information of the Rio de Janeiro City Health Department, presented a paper dealing with the rabies situation in the city. After pointing out that, according to Rosenau, human rabies was never registered in Australia, an insular country, and that the disease had been stamped out many years ago in Denmark, Sweden, Norway and the British Isles, Dr. Fontenelle said that the mortality statistics of the large cities of the United States show that the annual death rate from rabies has been at the average level of 0.03 per hundred thousand for an aggregate of more than 35 million population in the last decade. In the city of Buenos Aires, Argentina, the mortality returns for the last five years give a mean annual death rate of 0.04 per hundred thousand for a population of 2.5 million, but in Rosario, Argentina's second city, with a population of a little more than 500,000, the mean annual death rate for the last five years is 0.33 per hundred thousand. As for Brazil, Dr. Fontenelle studied the mortality from rabies for the decade 1933-1942 in nine of the largest cities, the present population of which ranges from 113,000 to 1,980,000. For eight of these cities the mean annual death rate from rabies for this period was as follows: Rio de Janeiro (40 deaths), 0.23 per hundred thousand; São Paulo (28 deaths), 0.23; Recife (28 deaths) 0.21; Salvador (8 deaths) 0.27; Porto Alegre (6 deaths) 0.23; Belo Horizonte (9 deaths) 0.47; Belem (14 deaths), 0.66, and Fortaleza (17 deaths) 1.00.

It is the opinion of the author that the control of rabies in a city like Rio de Janeiro consists mainly in the control of stray dogs, many of which are infected by the disease, which often goes unreported by laymen. During the first half of this year, out of many animals examined, 103 have been recognized as affected by rabies: 98 dogs, 3 cats, 1 monkey and 1 rabbit. Therefore it is really the dog, but usually only the "stray dog," which is a concern to the public health.

Many facilities are being offered to the population for the preventive Pasteur treatment of the victims of dog bites; all the fifteen health centers and ten of the municipal hospitals give free treatment, using the Fermi vaccine prepared at the Public Health Laboratory of the city.

Antirabic Service

In May 1930 the Instituto Pinheiros of São Paulo started an antirabic service with the following procedure:

1. The physician requests the first doses of antirabic vaccine by telegraph or telephone.
2. He receives at once a box with six doses.
3. He completes an information form giving an account of the accident and mails it back to the institute.
4. The institute classifies the severity of the case and makes further periodic remittances of recently prepared vaccine.

In remote towns the institute maintains, preferably in the local hospital in a refrigerator, a number of doses of vaccine valid for four months for the immediate beginning of treatment: These are the so-called antirabic stations, which act as follows:

1. On beginning a treatment, the station notifies the institute.
2. By return mail a fresh box of vaccine is sent to replace the one in use, together with doses for the continuation of the treatment in the case just begun.
3. Whenever the valid limit of a vaccine has expired at a station, immediate replacement is made.

The stations in very remote towns, where communication with the institute is difficult, are in contact with intermediate stations, which receive vaccines of recent preparation every week and which are able to classify the severity of the cases and provide for the continuation of treatments.

From May 1930 to June 30, 1942, 12,073 persons were treated, 695 with a vaccine of the Fermi type, in a 6 per cent suspension, phenolized at 1 per cent; 8,238 with a 5 per cent suspension; 3,140 with a 4 per cent suspension. Results are as follows: real failure, 0; false failure, 0.024 per cent; neuro-paralytic accidents, 0.008 per cent; cases of shock characterized by a syncopal state immediately after the injections, passing and without after-effect, 0.19 per cent; cases of badly characterized shock, 0.06 per cent; general reactions, 0.08 per cent. There were 205 antirabic stations on June 30, 1942, 204 stations in Brazil, and 1 in the capital of the republic of Paraguay.

The decentralized service solves the economic side of antirabic vaccination, which is of great importance in a vast country like Brazil, with difficulties in communications, and where salaries are low.

The solution of the economic problem signifies an important social attainment as it gives the benefits of science both to the individual with means, who could leave his home town and stay for weeks under treatment in a town where there is a Pasteur institute, and to persons who could not afford to travel to the place of treatment indicated.

Marriages

FRANK ERNEST PERRON JR. to Miss Jeannette Benoit, both of Manchester, N. H., in Newton, Mass., recently.

ASHBY TURNER RICHARDS, Harrisonburg, Va., to Miss Evelyn Rosaline Suter of Staunton, June 14.

HARRY HALL WOMACK JR., Fort Worth, Texas, to Miss Margaret Harris of Galveston, May 22.

DAVID L. GREENLEES, Greensboro, Ala., to Miss Ester Schreckengost of Butler, Pa., July 17.

LOUIS W. PUTZIG, Blanchard, Mich., to Miss Vera Stevens of Six Lakes in Dearborn, June 24.

JOHN TABB WALKER to Miss Evelyn Chamblin Murrell, both of Richmond, Va., July 6.

CHARLES W. IOBST, Emmaus, Pa., to Miss Barbara J. Strobel of Allentown, July 15.

KENNETH P. KNUDSON, De Forest, Wis., to Miss Ruth Higdon, May 13.

GEORGE VASH to Miss Virginia Evans, both of Hinsdale, Mass., June 28.

Deaths

Frederic Atwood Besley ☉ prominent surgeon and leader in surgical organizations, died August 16, aged 76, in the Victory Memorial Hospital, Waukegan, Ill., following a prostatectomy.

Dr. Besley was born in Waukegan, April 19, 1868. He received his early education at the Chicago Manual Training School. After graduating at Northwestern University Medical School in 1894 he served an internship and residency at Cook County Hospital until 1896. In 1900 he was named professor of surgery at the Postgraduate Medical School, Chicago, a position he held until 1908; for a year in 1901 he held a similar appointment at the Woman's Medical College of Northwestern University. In 1899 he joined the staff of Northwestern as clinical instructor in surgery, subsequently advancing through the years until 1915, when he was made professor of surgery.

During the first world war Dr. Besley served as chief surgeon of the Northwestern University Base Hospital Unit number 12. He was with the English forces soon after the entrance of the United States in the war, later serving with the American forces in France. He was commissioned as a major and was retired with the rank of colonel.

After the war Dr. Besley established in Waukegan the Besley-Waukegan Clinic. He had been a member of the staff of a number of hospitals including Cook County, Wesley Memorial and Mercy hospitals, Chicago, and the Victory Memorial Hospital, Waukegan. He was consultant to the Veterans Administration Facility, Downey.

He was a founder member of the American College of Surgeons in 1913, serving as treasurer from 1926 to 1937, president and member of the board of regents from 1937 to 1938, when he became secretary, a position he held at the time of his death. From 1926 to 1939 he was chairman of the college's committee on industrial medicine and surgery. He was also a founder member of the American Board of Surgery. In 1905, with the late Drs. Franklin H. Martin, Allen B. Kavel, John Hollister, all deceased, and Dr. William R. Cubbins, Dr. Besley served as a founder member of the editorial board of *Surgery, Gynecology and Obstetrics*, holding active membership on the board since its establishment.

He had been a member of the board of directors and treasurer and executive vice president of the Surgical Publishing Company, a member of the American Surgical Association and of the Chicago Surgical Society, serving the last group early in his career as treasurer and later president. He was also president of the Lake County Medical Society in 1930. In 1941 he was appointed a member of the Commission on Physical Rehabilitation of the Health and Medical Committee of the Federal Security Agency.

Wilbert B. Hinsdale, Ann Arbor, Mich.; Homeopathic Hospital College, Cleveland, 1887; formerly dean and professor of the theory and practice of medicine and clinical medicine at the University of Michigan Homeopathic Medical School; president of the American Institute of Homeopathy in 1913 and the Michigan Academy of Science, Arts and Letters in 1931; member of the American Association for the Advancement of Science and the Michigan State Archaeological Society; had been in charge of the Great Lakes division, University of Michigan Museum of Anthropology; health officer in Ann Arbor for many years and served as a member of the board of education; formerly medical director of the University of Michigan Homeopathic Hospital; for many years member and for five years president of the board of trustees of the Michigan Tuberculosis Sanatorium in Howell; for a long period a member of the board of trustees of the Hiram College, Hiram, Ohio; author of "Primitive Man in Michigan," "The Indians of Washtenaw County," "The First People of Michigan," "Archaeological Atlas of Michigan" and "Distribution of Aboriginal Population of Michigan"; died July 25, aged 93, of arteriosclerosis.

Lawrence Joseph Rhea, Montreal, Que., Canada; Johns Hopkins University School of Medicine, Baltimore, 1906; member of the American Association of Pathologists and Bacteriologists, the Association of American Physicians, International Association of Medical Museums, and the Canadian Medical Association; professor of pathology at McGill University Faculty of Medicine, where he was director of the Pathological Institute; assistant professor of pathology at the Harvard Medical School, Boston, 1912-1913, instructor, 1909-1910, and assistant in pathology, 1908-1909; held the rank of major during World War I, with number three Canadian General Hospital, Royal Canadian Army Medical Corps; formerly resident in pathology at the Peter Bent Brigham Hospital, Boston; director of the pathologic laboratory of the Montreal General Hospital, where he died July 3, aged 67.

Edmund F. Collins ☉ Detroit; Western University Faculty of Medicine, London, Ont., Canada, 1912; a fellow of the American College of Hospital Administrators; life member of the American Hospital Association and Michigan Hospital Association; past president of the Greater Detroit Hospital Council; treasurer and member of the board of trustees of the Michigan Hospital Service; member of the American Congress of Obstetrics and Gynecology; first associated with the Grace Hospital as assistant resident physician in 1916 and held numerous executive positions until his appointment as director in 1937; appointed treasurer of the hospital in 1943; died June 29, aged 55, of coronary thrombosis.

Adolphus William Foertmeyer ☉ Cincinnati; Medical College of Ohio, Cincinnati, 1905; also a pharmacist; assistant professor of psychiatry at the University of Cincinnati College of Medicine; member of the American Psychiatric Association and the Central Neuropsychiatric Association; since January 1942 probate court alienist; for two terms county coroner; formerly federal jail physician; served overseas during World War I; major, medical reserve corps, U. S. Army, not on active duty; on the staffs of St. Mary's, Bethesda, Christ, Jewish, Cincinnati General, Deaconess and Good Samaritan hospitals; died June 24, aged 64.

Stephen Trent Barnett ☉ Atlanta, Ga.; University of Virginia Department of Medicine, Charlottesville, 1896; past president of the Fulton County Medical Society; member of the Southern Medical Association; fellow of the American College of Surgeons; served as assistant to chair, clinical gynecology, Atlanta College of Physicians and Surgeons; professor of obstetrics and clinical gynecology at the Atlanta Medical College from 1907 to 1915; visiting gynecologist at Grady, Emory University, Crawford W. Long Memorial, Georgia Baptist hospitals and St. Joseph's Infirmary; died June 27, aged 73.

John Henry Gilpin, Cheboygan, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902; member of the Michigan State Medical Society; served overseas during World War I; formerly Indiana commander of the Veterans of Foreign Wars; at one time deputy health commissioner, health commissioner, secretary of the board of health and school physician in Fort Wayne, Ind.; served as commandant of the Indiana State Soldiers' Home in La Fayette; formerly county coroner; district health officer of Cheboygan, Presque Isle, Montmorency and Alpena counties; died June 22, aged 67.

David Hartin Boyd ☉ Pittsburgh; Harvard Medical School, Boston, 1906; specialist certified by the American Board of Pediatrics, Inc.; associate professor of pediatrics at the University of Pittsburgh School of Medicine; member of the American Academy of Pediatrics; past president of the Pittsburgh Academy of Medicine; served overseas during World War I; attending pediatrician, Allegheny General, Children's and Presbyterian hospitals, Pittsburgh, and the Columbia Hospital, Wilkensburg; consulting pediatrician, Sewickley Valley Hospital, Sewickley; died July 10, aged 64.

William A. Harris, Spotsylvania, Va.; Medical College of Virginia, Richmond, 1901; member of the Medical Society of Virginia; served three terms in the general assembly as delegate from Fredericksburg and Spotsylvania County; a lieutenant colonel in the medical corps of the U. S. Army during World War I and served in France; served as county coroner, as secretary of the board of public roads and as county health officer; formerly member of the board of visitors of Virginia Polytechnic Institute; died suddenly May 25, aged 66, of coronary thrombosis.

Frederick William Adamson, Lake Worth, Fla.; Northwestern University Medical School, Chicago, 1894; drowned at West Palm Beach, June 21, aged 76.

O. Prescott Bennett, Washington, Ill.; Chicago Homeopathic Medical College, 1889; College of Physicians and Surgeons, Chicago, 1890; represented his township on the Tazewell County board of supervisors from 1928 to 1932, holding chairmanship for one year; served overseas during World War I; chief of staff of Washington Hospital; died June 21, aged 75, of coronary thrombosis.

Nicholas Francis Bray, Springfield, La.; St. Louis College of Physicians and Surgeons, 1908; member of the Louisiana State Medical Society; died June 16, aged 64, of carcinoma of the esophagus caused by injury to the neck received in an automobile accident.

Prentice M. Bristow, Stanton, Texas; University of Tennessee Medical Department, Nashville, 1905; served as city and county health officer; died in the Big Spring Hospital, Big Spring, June 12, aged 66, of carcinoma of the liver.

Ray Callis Bunch ☉ Nashville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1916; on the staffs of the Protestant, Nashville General and Vanderbilt hospitals; died June 22, aged 53, of hypertension.

Garrard Peyton Cherry, Mangum, Okla. (licensed in Texas under the Act of 1907 and in Oklahoma by years of practice); member of the Oklahoma State Medical Association; died May 14, aged 82, of senility.

Thomas J. Costello, Seattle; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; formerly on the staff of St. Joseph's Hospital, Lewiston, Idaho; died June 18, aged 68.

Francis William Davis, New York; University of the City of New York Medical Department, New York, 1893; member of the Medical Society of the State of New York; served on the staff of the New York Hospital; died in St. Vincent's Hospital June 12, aged 82, of cerebral thrombosis and diabetic acidosis.

Charles Neilson Denison, Waldoboro, Maine; Long Island College Hospital Brooklyn, 1893; formerly health officer of Cheshire, Conn., and New Hartford, Conn.; served as a member of the staffs of the St. Mary's Hospital, Waterbury, Conn., and Miles Memorial Hospital, Damariscotta; died June 7, aged 73, of cardiac asthma.

Lloyd Byron Dochterman, Williston, N. D.; Detroit College of Medicine, 1900; member of the North Dakota State Medical Association; also a pharmacist; health officer of Williston; served during World War I; member of the library board; on the staffs of the Mercy and Good Samaritan hospitals; died June 6, aged 66, of retroperitoneal hemorrhage.

Willard F. Doolittle ☉ New York; Columbia University College of Physicians and Surgeons, New York, 1902; an Affiliate Fellow of the American Medical Association; died in St. Luke's Hospital June 5, aged 72.

Andrew Francis Downing, Cambridge, Mass.; Harvard Medical School, Boston, 1904; member of the Massachusetts Medical Society; at one time examiner for the Massachusetts Civil Service Commission; served on the staffs of the Boston Dispensary, St. Elizabeth's Hospital and the Massachusetts General Hospital, Boston, and the Cambridge City Hospital; died June 2, aged 66, of chronic myocarditis.

Ralph Orr Early ☉ Oklahoma City, Okla.; Rush Medical College, Chicago, 1901; served during World War I; died in St. Anthony Hospital June 6, aged 64, of cerebral hemorrhage.

Anthony Bartholomew Erlain ☉ Cashtown, Pa.; Laval University Faculty of Medicine, Quebec, Que., Canada, 1929; served during World War I; contract surgeon with the U. S. Army for six months; died in Pittsburgh June 2, aged 45, of coronary occlusion.

Ewing Oliphant Evans, San Antonio, Texas; Kentucky School of Medicine, Louisville, 1892; member of the State Medical Association of Texas; president of the city school board from 1918 to 1922; surgeon for the Mexican International Railroad and the Coahuila and Alamo Coal Companies from 1895 to 1902; died June 8, aged 75, of carcinoma of the colon.

George W. Fletcher, Montrose, Ark.; Memphis (Tenn.) Hospital Medical College, 1896; member of the Arkansas Medical Society; served as president of the Ashley County Medical Society; died May 23, aged 74, of chronic nephritis.

Forrest Henry Frey ☉ Wausau, Wis.; Rush Medical College, Chicago, 1913; past president and secretary of the Marathon County Medical Society; on the staffs of the Wausau Memorial Hospital and St. Mary's Hospital, where he died May 31, aged 55, of cerebral hemorrhage and chronic nephritis.

Otto Albert Gahl, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; died in the City of Chicago Municipal Tuberculosis Sanitarium, June 16, aged 61, of pulmonary tuberculosis.

Albert Mouzon Gantt, Houston, Texas; Louisville (Ky.) Medical College, 1902; member of the State Medical Association of Texas; at one time on the staff of St. Paul's Sanitarium in Dallas; died June 2, aged 68, of coronary thrombosis.

Arthur Clesson Hagedorn, Gloversville, N. Y.; Albany (N. Y.) Medical College, 1892; member of the Medical Society of the State of New York; for many years coroner of Fulton County; on the staff of the Nathan Littauer Hospital, where he died June 23, aged 75, of coronary occlusion.

Germain B. Hale, West Liberty, Ohio; Chicago Homeopathic Medical College, 1894; served as county coroner; died June 11, aged 71, of duodenal ulcer and hemorrhage.

George Dempster Hamlen, Bayside, N. Y.; University of the City of New York Medical Department, 1890; at one time instructor in obstetrics and gynecology at the Cornell University Medical College and on the staff of the Bellevue Hospital in New York; died June 5, aged 77, of heart disease.

Foster Pierce Harbin, Brunswick, Ga.; Atlanta Medical College, 1914; member of the Medical Association of Georgia; associated with the Glynn County Board of Health, in charge of the mobile health unit; died June 14, aged 55, of dilatation of the heart.

Fleet Hiram Harrison ☉ Imlay, Nev.; Missouri Medical College, St. Louis, 1897; a captain in the medical corps of the U. S. Army during World War I; physician and surgeon for the Southern Pacific Railroad; at one time health officer of Alpine County, Calif.; on the staffs of St. Mary's and Washoe County General hospitals, Reno; died in the Southern Pacific General Hospital, San Francisco, June 16, aged 69, of coronary occlusion.

William Cullen Hawken ☉ Detroit; Detroit College of Medicine and Surgery, 1928; medical examiner for the board of education; on the staffs of the Mount Carmel Hospital, Receiving Hospital, St. Mary's Hospital and the Providence Hospital, where he died June 7, aged 42, of arteriosclerotic hypertension with cerebral edema.

Alexander S. Holden, Ellijay, Ga.; Atlanta Medical College, 1897; died in a hospital in Atlanta April 16, aged 78.

Gregory H. Hovnanian, Chicago; Medico-Chirurgical College of Philadelphia, 1890; died June 9, aged 80, of pulmonary tuberculosis.

Harry Newell Howe ☉ Greenfield, Mass.; Columbia University College of Physicians and Surgeons, New York, 1899; served on the draft medical advisory board during World War I; president of the Franklin District Medical Society, 1916-1917; served on the board of health and as school physician; on the staff of the Franklin County Public Hospital, where he died May 11, aged 72, of coronary thrombosis.

John Franklin Iden, Dresden, Ohio; University of Louisville (Ky.) Medical Department, 1894; member of the Ohio State Medical Association; on the staffs of the Good Samaritan Hospital and the Bethesda Hospital, Zanesville, where he died June 11, aged 75, of chronic myocarditis and generalized arteriosclerotic cardiovascular disease.

Allan Smith Ironside, Haddonfield, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1889; on the staff of the West Jersey Homeopathic Hospital, Camden; died May 31, aged 76, of chronic myocarditis, toxemia and purulent cystitis.

William Francis James, Honolulu, Hawaii; Medical Department of Tulane University of Louisiana, New Orleans, 1893; honorary member of the Hawaii Territorial Medical Association; veteran of the Spanish-American War; for many years acting assistant surgeon in the U. S. Public Health Service; died May 23, aged 83, of senility.

Paul Lemmer Jenny ☉ Pittsburgh; University of Pittsburgh School of Medicine, 1928; instructor in physical therapy at his alma mater; on the staffs of the Passavant and Elizabeth Steel Magee hospitals; died May 28, aged 43, of cerebral embolism.

Reuel Hammond Jones ☉ New Carlisle, Ohio; Ohio Medical University, Columbus, 1905; died May 17, aged 68, of fibrosarcoma.

Jerome Howard King, Mansfield, Ohio; Cleveland Medical College, Homeopathic, 1894; formerly county coroner; died May 13, aged 74.

Andrew Jackson Kisner, Natchez, Miss.; Memphis (Tenn.) Hospital Medical College, 1910; died June 1, aged 58, of chronic myocarditis and myocardial degeneration.

William Carroll Lindsay, Kellogg, Idaho; Northwestern University Medical School, Chicago, 1910; member of the Idaho State Medical Association; past president of the Shoshone County Medical Society; served as a member of the department of law enforcement; served as health officer of Kellogg; formerly health officer of Shoshone County; on the staff of the Providence Hospital, Wallace, where he died June 4, aged 61, of hemorrhage due to gastric ulcer.

Luther M. Linker, Elmira, Ill.; Louisville (Ky.) Medical College, 1895; died June 14, aged 77, of mucous colitis.

Harold Baughman Miller, Lincoln, Neb.; Jefferson Medical College of Philadelphia, 1890; also a pharmacist; formerly professor of materia medica and therapeutics and electrotherapeutics at the Nebraska College of Medicine; member of the

medical staff of the Security Mutual Life Insurance Company; on the staff of St. Elizabeth Hospital, where he died May 22, aged 82, of uremia and renal insufficiency.

Thomas Franklin Petway, Atlanta, Ga.; Atlanta School of Medicine, 1909; member of the Medical Association of Georgia; died in the Crawford W. Long Hospital May 22, aged 65, of acute pyelonephritis.

William A. Repp Ⓢ Detroit; Detroit College of Medicine, 1895; also a pharmacist; formerly associate professor of gynecology at his alma mater; fellow of the American College of Surgeons; a founder and consulting gynecologist of the Florence Crittenton Home; attending physician and surgeon to St. Vincent Orphan Asylum; chief consultant at St. Mary's Hospital, where he was a member of the staff for more than fifty years and where he died June 19, aged 71, of cardiac thrombosis.

Arthur W. H. Seiple, Larned, Kan.; Southern Homeopathic Medical College, Baltimore, 1898, member of the Kansas Medical Society; died in St. Rose Hospital, Great Bend, May 10, aged 74, of uremia, prostatic obstruction and diabetes mellitus.

Warren Seabury Simmons, Long Island City, N. Y.; College of Physicians and Surgeons, New York, 1892; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; adjunct professor of anatomy at the Long Island College Hospital, Brooklyn, from 1904 to 1914; served on the staffs of the Bushwick, Swedish and St. John's hospitals in Brooklyn; died May 2, aged 77, of heart disease.

David English Smith Ⓢ Bonne Terre, Mo.; Washington University School of Medicine, St. Louis, 1914; Army Medical School, 1917; formerly a major in the medical corps of the U. S. Army; chairman of the staff, Bonne Terre Hospital; died May 5, aged 55.

Robert Thomas Stearns, Scituate, Mass.; Harvard Medical School, Boston, 1902; died April 20, aged 68.

Charles Frank Sullivan, Houston, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, Fort Worth, 1918; died May 23, aged 54.

Walter Lee Swindell, Swanquarter, N. C.; Baltimore Medical College, 1908; deputy health officer of Hyde County; physician for the local draft board; died June 12, aged 65, of heart disease.

Theodore Evelyn Townsend, Westwood, N. J.; Long Island College Hospital, Brooklyn, 1891, served as a member of the staff of the Hackensack Hospital, Hackensack, where he died June 18, aged 74, of carcinoma of the pancreas.

Frank Landale Tucker, Brooklyn; College of Physicians and Surgeons, New York, 1891; senior surgeon and formerly member of the board of directors of the Brooklyn Eye and Ear Hospital; died May 28, aged 77, of intradermal carcinoma of the foot.

James Arthur Tucker Ⓢ Baton Rouge, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1904; for many years attending surgeon to the Louisiana State University and the Louisiana State School for the Deaf; on the staffs of Our Lady of the Lake Sanitarium and Baton Rouge General Hospital; died May 8, aged 65.

Edward Joseph Tulleys, South Salem, Ohio; the Hahnemann Medical College and Hospital, Chicago, 1899; member of the Ohio State Medical Association; on the staff of the

Chillicothe Hospital, Chillicothe, where he died June 1, aged 69, of cerebral hemorrhage.

Maud M. Foy Uhl, Glendale, Calif.; University of Buffalo School of Medicine, 1891; died May 2, aged 76, of chronic myocardial degeneration.

McClellan Vance, London, Ohio; Eclectic Medical Institute, Cincinnati, 1887; died May 8, aged 82, of cerebral hemorrhage.

Maurice B. Van Cleave, Terre Haute, Ind.; Hering Medical College, Chicago, 1900; member of the Indiana State Medical Association; past president of the Vigo County Medical Society; served as city health officer; past president of the staff of St. Anthony's Hospital; died June 11, aged 69, of organic heart disease and coronary sclerosis.

Charles Emmett Walker Ⓢ Sanatorium, Miss.; University of Tennessee College of Medicine, Memphis, 1916; served in France during World War I; assistant superintendent of the Mississippi State Tuberculosis Sanatorium; died June 26, aged 54, of coronary thrombosis.

Robert F. Wells, Manchester, Md.; Baltimore Medical College, 1892; died June 1, aged 78, of peritonitis and gangrene of the cecum.

Betty Whitson, Boise, Idaho; Washington University School of Medicine, St. Louis, 1941; interned at the Flower

and Fifth Avenue Hospitals in New York; resident physician at the Medical Center of Jersey City, N. J., where she died May 20, aged 32.

Hal Drummond Wilmeth, Barinston, Neb.; Lincoln Medical College, Eclectic, 1916; died in the Veterans Administration Facility, Knoxville, Iowa, May 4, aged 52, of coronary occlusion.

Thomas L. Wilson, Bellwood, Pa.; College of Physicians and Surgeons, Baltimore, 1891; member of the Medical Society of the State of Pennsylvania; for many years Bellwood councilman and medical examiner for Bellwood borough and Antis township schools; died May 7, aged 81, of hypostatic pneumonia.

CAPT. HARRY P. SINGLEY, M. C.,
A. U. S., 1909-1944

LIEUT. (JG) MARTIN H. BRAUN
(MC), U.S.N.R., 1914-1943

Manoug Garabet Yardume, Boston; Harvard Medical School, Boston, 1900; served as medical consultant for the John Hancock Insurance Company; associated with the Massachusetts General, Faulkner and Peter Bent Brigham hospitals; died June 19, aged 72, of angina pectoris.

KILLED IN ACTION

Martin Herman Braun, Kew Gardens, N. Y.; Howard University College of Medicine, Washington, D. C., 1940; interned at the Harlem Hospital in New York; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on June 12, 1942; aged 29; declared missing in action on Nov. 12, 1942; killed in action in the Atlantic area; presumptive date of death Nov. 13, 1943, according to the Navy Department.

Harry Paul Singley, Ventnor, N. J.; Jefferson Medical College of Philadelphia, 1936; member of the Medical Society of New Jersey; served an internship at the Western Pennsylvania Hospital, Pittsburgh; commissioned a first lieutenant in the medical corps, Army of the United States, on June 13, 1942; later promoted to captain; killed in the invasion of France, June 6, aged 34.

Bureau of Investigation**Correspondence****STIPULATIONS****Agreements Between Federal Trade Commission and Promoters of Various Products**

Following are abstracts of stipulations in which promoters of "patent medicines," medical devices and cosmetics have agreed, following action by the Federal Trade Commission, to discontinue certain misrepresentations in their advertising. These stipulations differ from the "Cease and Desist Orders" of the Commission in that such orders definitely direct the discontinuance of misrepresentations. The abstracts that follow are presented primarily to illustrate the effects of the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act on the promotion of such products:

Athygienic Foot Powder and Athygienic Foot Glove.—That these products are remedies for corns or foot ailments generally were misrepresentations which the Wilson Industries, Inc., of Chicago agreed to eliminate from their advertising in a stipulation that they entered into with the Federal Trade Commission in October 1943.

Blue Bonnet Mineral Water Crystals.—This product is sold by Zeta M. Pack, trading as Loyal Distributing Company, Wheeling, W. Va. In September 1943 this person stipulated with the Federal Trade Commission that she would cease representing that the preparation will correct excess acidity, build up the system, keep the body healthy, or help one to regain good health; that it will increase resistance to colds, grippe and other ailments, insure good appetite or sound sleep or restore energy; that it will be beneficial for conditions of fatigue, listlessness or lack of "pep," or rid the system of, or keep it free from, poisons. She further agreed to discontinue any advertisement which represented that the product is in all cases harmless, or which failed to reveal that it should not be taken by persons suffering from abdominal pain or other symptoms of appendicitis; provided, however, that such advertisements need only contain the statement, "Caution: Use only as directed" if the label instructions for use include a warning to the same effect.

Dar-Sal.—This is a dehydrated product of goat's milk put out by J. F. Darrington, trading as Darrington's, Marshfield, Ore. In September 1943 Darrington stipulated with the Federal Trade Commission to cease representing that Dar-Sal is made by a secret process or possesses unique or special properties which are not present in other dehydrated products of goat's milk; that it has any value when used in connection with the treatment of run-down conditions, nervous disorders, stomach trouble, eczema, asthma, hyperacidity, rheumatism, paralysis or arthritis; that it is a cold preventive or will improve the user's health or build up his resistance to infectious diseases.

Dr. Carolus M. Cobb's Nasal Spray for Sinus Relief.—That this will relieve sinus trouble or the pain of headaches associated therewith, or open the sinus passages, were misrepresentations which Estelle Cobb Brown, East Lynn, Mass., agreed to eliminate from the advertising in a stipulation that she entered into with the Federal Trade Commission in September 1943.

Dr. True's Elixir.—In September 1943 the Federal Trade Commission accepted a stipulation from Dr. J. F. True & Company, Inc., Auburn, Maine, and its advertising agency, the S. A. Conover Company, Boston, in which these concerns agreed to discontinue any advertisement which failed to reveal that the "Elixir" should not be used in the presence of symptoms of appendicitis, such as abdominal pain, nausea or vomiting. The stipulation permitted, however, that such advertisements need contain only the statement, "Caution: Use only as directed" if the same warning were included in the directions on the label. In an earlier case (June 1937) the True concern had stipulated with the Commission that it would no longer advertise that the product was useful in treating ordinary ailments of children, and would safeguard health, gave children double protection, and contained no harmful ingredients.

"My Own Story of My Diabetes."—This is the title of a publication sold by George V. Harnetty, San Diego, Calif. In September 1943 Harnetty stipulated with the Federal Trade Commission to cease representing that by reading this work, a person "can learn a cure for diabetes." He further agreed not to publish or cause to be published any advertisement concerning this publication which would fail to reveal the material fact that the treatment referred to in the advertisement involves the use of a chemical or drug which will have irritant effects and may seriously interfere with the proper functioning of injured or diseased kidneys, and that its prolonged use may injure kidneys that are normal.

Vit-Mins and Vita-Food.—These are two names for one product put out by V. E. Michael of Ashtabula, Ohio. In October 1943 he stipulated with the Federal Trade Commission that he would no longer represent in his advertising that the preparation is the most complete vitamin or mineral product ever offered for sale; that it insures a vigorous personality, a disease-resisting body, good teeth and a clear complexion; that it improves eyesight, relieves fatigue, reduces nervousness and aids digestion; that it prevents sinus trouble, catarrh, headaches, arthritis, rheumatism and ailments of the liver, kidneys and heart, and assists in overcoming excess weight and preventing infection from entering the body.

DUSTING POWDER FOR SURGICAL GLOVES

To the Editor:—In THE JOURNAL, Dec. 11, 1943, in a study of possible substitutes for talcum powder, Verda, Kidd and I stated that potassium bitartrate was a satisfactory dusting powder but that it tended somewhat to shorten the life of rubber gloves. This statement is subject to correction. We found later, after changing the brand of glove we had been using, that there was no determinable deteriorating influence on the life of the glove. We were prompted to investigate this particular phase of the work by a personal communication to us from the Research Laboratory of the Wilson Rubber Company, stating that a very carefully checked set of experiments made by the laboratory failed to reveal any adverse effect of potassium bitartrate on either latex or pure gum rubber gloves.

A second point of importance that we set out in our paper is the impossibility of using starch as a dusting powder because of the gelatinization resulting from the reaction of starch to steam sterilization. Since the publication of our paper, the Research Laboratories of the Corn Products Refining Company have cooperated with us most kindly and most enthusiastically in the attempt to overcome the gelatinizing property of starch. They have finally developed, by the application of new processes, recently developed by them, a special starch dusting powder that does not gelatinize when subjected to boiling or to steam sterilization and that has no deteriorating effect on the gloves. We have been using a sample of this new starch dusting powder for twelve weeks in the operating rooms of the Barnard Free Skin and Cancer Hospital and have found that it meets all clinical requirements. Both the surgeons and the operating room personnel have found it thoroughly satisfactory. Experiments on animals showed this new starch dusting powder to be totally innocuous.

This new starch dusting powder, unfortunately, cannot yet be furnished for general use, because current difficulties with equipment priorities may preclude its manufacture in quantity until after the war. In the meantime we have been receiving such favorable reports concerning the potassium bitartrate powder that we advise its substitution for talcum until such time as the new starch can be produced in quantity. Talcum cannot be removed from the operating room at too early a moment.

M. G. SEELIG, M.D., St. Louis.

Director of pathology, the Barnard
Free Skin and Cancer Hospital.

SULFADIAZINE IN NASOPHARYNGITIS

To the Editor:—Regarding the article "Sulfadiazine in the Treatment of 200 Cases of Acute Catarrhal Nasopharyngitis" by Capt. F. B. Faust and Capt. J. H. Simmons in THE JOURNAL, June 24, page 552, "hospital days" as a determining factor in the response of a disease to a therapeutic agent is an extremely loose one, especially in a station hospital in the Army.

Many patients who would normally be considered cured and discharged are often maintained as patients because of technical or administrative reasons. As a result, statistics solely based on hospital days in an army installation may not be entirely accurate.

Furthermore, it is doubtful that the degree of morbidity of nasopharyngitis can be based solely on the extent of temperature elevations. Many nasopharyngitis patients have acute symptoms and appear severely ill in the presence of normal temperatures or slight elevations above normal.

Even assuming for the sake of argument that hospital days could be accepted as reliable criteria for determining therapeutic results, the only important conclusion that could possibly be reached from the authors' statistics is omitted, viz that the routine administration of sulfadiazine is without value in the treatment of nasopharyngitis, which fact is generally accepted by most clinicians. This conclusion might be drawn from the following statement from the article in question: 'The total hospital days in the series treated with sulfadiazine was 648 days. The total hospital days in the control series was 462 days. The average number of days was 5.6 for both series.'

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Statutory Restrictions on Advertising by Physicians Valid.—A law enacted in Maryland in 1943 (Acts, 1943, c. 600) prohibits physicians from advertising. However, the law permits a physician (1) to use a personal professional card not larger than 3½ by 2 inches, on which may be printed his name, title, address, specialty, telephone number and office hours, (2) to mail to bona fide patients a removal notice not larger than 5 by 7 inches containing the information permitted on a personal professional card and (3) to exhibit on the building in which his office is located not more than two signs on which may be placed his name and degree, the letters of which shall not exceed 3 inches square and to exhibit such a sign on the door of his office. A physician violating the provisions of the law is subject to a fine of from \$50 to \$300 for each offense. The law also denominates a violation of its provisions unprofessional conduct, which, in turn, is one of the causes set out in the medical practice act for the revocation of a license to practice medicine.

Davis, a licensed physician and who prior to the enactment of the 1943 law customarily advertised his skill in the treatment of venereal diseases, brought suit against the state of Maryland and certain individuals constituting the State Board of Medical Examiners for a declaratory judgment that the 1943 statute was unconstitutional. Since he had ceased to advertise, he alleged, because of the prohibition of the statute his professional income had been cut in half. The statute was unconstitutional, he claimed, because (1) it was not a valid exercise of the police power of the state but deprived him of his property without due process of law and (2) it was arbitrary and discriminatory and deprived him of the equal protection of the laws guaranteed by the federal constitution. A demurrer was interposed by the defendants, based on the theory that a state is immune from suit by an individual. The trial court offered Davis an opportunity to amend his bill of complaint so as to eliminate the state of Maryland as a party and on his refusal to amend sustained the demurrer and dismissed the bill. Davis then appealed to the Court of Appeals of Maryland.

The appellate court first discussed the propriety of using the declaratory proceeding to test the constitutionality of a statute and held that it was proper under the circumstances present in this case. The court next discussed the question as to whether or not the immunity of a state from suit is modified by the enactment of legislation providing for declaratory judgments, holding that even in a declaratory judgment proceeding the state is immune from suit and that hence the action of the trial court was proper in dismissing the bill of complaint because the state was made a party defendant to the proceedings.

Even though, for this reason alone, affirmance of the decree adverse to Davis was required, the court undertook to discuss the constitutional questions raised by Davis. The right to carry on any lawful business, trade or calling, said the court, is subject to regulation by the legislature under the police power of the state whenever necessary to promote in some degree the public health, morals or welfare. The legislature in enacting the statute in question aimed to aid in maintaining the high standard of ethics of physicians. The state has the power to see that only persons with special training and skill shall undertake the difficult and responsible duties of dealing with the health and lives of the people. The state is vitally concerned in attracting young people of ability to the practice of medicine and also in making it possible for those who are engaged in practice to survive without facing unreasonably com-

petition, thus leaving them free to improve their qualifications without the necessity of devoting a large part of their time and effort to ruthless competitive pursuit for patients. The Maryland legislature determined that physicians of mediocre ability are likely to make up for lack of genuine merit by knowledge of mass psychology and skill in appealing to the emotions and hopes of the uninformed and credulous. Under the traditional method of professional advancement as a result of recommendations of satisfied patients, the progress of a practitioner may be slow but it bears more relation to merit, whereas mediocre practitioners who advertise extensively can obtain new patients by clever publicity as fast as the discovery of their mediocrity causes the loss of patients. It is well established that the state may lawfully forbid any advertising by medical practitioners that solicits patronage for the advertisers. *Laughney v Maybury*, 145 Wash 146, 259 P 17. The legislature continued the court, had the right to determine, and did determine, that the public interest would be injuriously affected by unseemly competition of physicians for patients without any restraint as to methods of advertising and that the regulation of advertising by physicians is necessary for the public health, morals and welfare.

Davis argued that he was not objecting to a law prohibiting deceptive advertising or schemes to take advantage of the public, or to advertisements offering professional superiority, guaranteed work or free examinations. He contended, however, that the restrictions imposed by the 1943 act are stricter than are necessary for the public health, morals or welfare. As illustrative of the type of advertising prohibited by the 1943 act but which advertising he contended should be permitted he exhibited one of his advertisements reading as follows:

Do you suffer from gland troubles? Call today and get my honest opinion of your condition. Thousands are sick and ailing from neglect. Call today and start yourself on the road to health. One visit may save you many years of worry. Charges moderate. Terms for all.

Necessarily, answered the court, there are limits to the valid exercise of the police power of the state. Otherwise the state legislature would have unbounded power and the constitutional restrictions would be meaningless, since it would be enough to say that any piece of legislation was enacted for the purpose of conserving the health, morals or welfare of the people. If, therefore, a statute designed for the public health, morals or welfare has no real or substantial relation to those objects or is a manifest invasion of rights secured by the fundamental law, it is the duty of the court to adjudge accordingly and thereby give effect to the constitution. But the police power is broad in scope and the legislature is vested with large discretion to determine not only what is injurious to the health, morals or welfare of the public but also what measures are necessary or appropriate for the protection of those interests. The exercise of the police power may inconvenience individual citizens, increase their labor or decrease the value of their property. The courts will not interfere with the exercise of power except where the regulations are arbitrary, oppressive or unreasonable. The wisdom or expediency of the regulations is not subject to judicial review. Of course, the police power is subject to the limitations imposed by the state and federal constitutions on every power of government, and the legislature will not be allowed to invade the fundamental liberties of the citizen. But unless regulations are so utterly unreasonable and extravagant in their nature that the personal and property rights of the citizen are interfered with or destroyed unnecessarily and in a wholly arbitrary manner without due process of law, they do not extend beyond the power of the legislature to enact and they form no subject for interference by the court. Applying this test, we find that the statute under review is a valid exercise of the police power of the state.

Davis contended, lastly, that the 1943 act was an unconstitutional discrimination because the restrictions on advertising set forth in that act are limited to physicians and do not extend to other professional classes. The state, said the court, is not bound to deal alike with all these classes or to strike at all evils at the same time or in the same way. It can deal

with the different professions according to the needs of the public in relation to each. The decree of the trial court dismissing the complaint was accordingly affirmed—*Davis v State*, 37 A (2d) 880 (Md, 1944).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1934 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Ophthalmology, Cincinnati

27:467-588 (May) 1944

Metabolism of Cornea: Studies on Oxygen Consumption of Corneas of Riboflavin and Vitamin A Deficient Rats O. S. Lee Jr. and W. M. Hart.—p. 488.
*Use of Tyrothricin, Bacterial Extract, in Treatment of Marginal Ulcers of Cornea S. Bloomfield.—p. 500.
Exophthalmic Ophthalmoplegia: Report of Case with Thyrotoxicosis of Unusually Long Duration I. D. Fagin, R. W. Pagel and H. H. Sand.—p. 504.
Duties and Training of Orthoptic Technician W. B. Lancaster.—p. 515.
Treatment of Asthenopia—Nonpathologic and Nonrefractive in Origin R. H. Pino and Greta L. Hultin.—p. 520.

Congenital Cataract Following German Measles in Mother.—Reese directs attention to a report from Australia of an epidemic of German measles and the occurrence of congenital cataract and other anomalies in infants born to mothers who had German measles during gestation. He cites 3 cases observed in New York within the past few months. All 3 of Reese's patients had congenital cataracts and congenital heart lesions. All mothers contracted German measles within the first month of pregnancy, which was during a rather severe epidemic of German measles in the East. The following questions present themselves in connection with these anomalies: 1. Is the infection of the mother German measles? 2. Why hasn't the occurrence of congenital anomalies in the children so infected been noted before? 3. Are the congenital anomalies which are now appearing the result of a more virulent type of German measles or of an altered type, which may have gained access to this country through an increased traffic with Australia? 4. Has the cause and effect relationship between other infections of the mother in the first three months of pregnancy and congenital anomalies existed in the past but has not been recognized? 5. Can prophylactic measures be taken to prevent pregnant women from contracting German measles during the first three months of pregnancy? 6. Should abortion be induced in pregnant women who contract exanthems in the first three months of pregnancy?

Tyrothricin in Treatment of Marginal Ulcers of Cornea.—According to Bloomfield the most frequent type of marginal ulcer of the cornea is that associated with the more severe catarrhal conjunctivitis. In these cases the keratic complication is considered an extension of the septic process in the conjunctiva. Treatment with the usual antiseptics, occasionally supplemented by cauterization of the corneal lesion, usually results in rapid healing of the ulcer. Another group of marginal corneal ulcers, which is common in old people, is not associated with conjunctival inflammation. These arise as marginal, subepithelial infiltrates which coalesce and break down to form superficial erosions crescentic with the limbus. Local ciliary injection is usually present. Such superficial ulcers usually heal readily when antiseptic applications or cauterization and pressure dressings are employed. At the author's hospital 4 patients with this type of corneal ulcer were recently treated with tyrothricin because the ulcer was refractory to the usual treatments. Tyrothricin, a stable mixture of gramicidin and tyrocidine, is prepared from cultures of *Bacillus brevis*, a saprophyte found in sewage and soil. The poor absorbability and highly potent bacteriostatic action render it a safe and

effective antiseptic against gram positive organisms by topical administration or the irrigation of infected body cavities. Tyrothricin was used with gratifying results in 4 cases of corneal ulcer. The drug appears to be an effective therapeutic agent in this condition. It may be safely applied to the conjunctival sac in effective concentrations.

Werner's Syndrome, S. T. Herstone and J. Bower.—p. 639.

Bone Metastases as First Sign of Cancer of Gastrointestinal Tract.—Bertin points out that cases in which bone metastasis is the first sign are rare. Three persons sought relief from symptoms caused by bone involvement. None of these patients presented important symptoms referable to the gastrointestinal tract. In 1 case an earlier diagnosis might have been made if bleeding from the rectum which occurred at intervals over a period of five years had been carefully investigated. In 2 cases there was nothing in the history or examination to suggest the presence of a deep seated malignant disease. In 1 case the metastatic lesion of the rib was painless at the time the chest roentgenogram was made. The bone lesions in the other 2 cases were moderately painful and showed definite tumor formation. Cancer of the digestive tract was not suspected in any of the 3 cases. The probable location of the primary growth was suggested by the microscopic examination. Gastrointestinal x-ray studies were made only after the pathologic diagnosis of adenocarcinoma had been made, and in each case the primary growth was found in the gastrointestinal tract: once in the stomach and twice in the sigmoid colon. Many of these cases are missed because it is usually not practical to make a complete x-ray examination of the entire osseous system unless there is a suspicion or sign or symptom suggesting bone involvement. The 3 cases were discovered in a series of 186 cases of carcinoma of the gastrointestinal tract over a period of ten years.

Salmonella Cholerae Suis Meningitis: Report of Case and Review of Literature on Salmonella Meningitis, E. R. Niter.—p. 425.

Myocarditis Associated with Dietary Deficiency.—The subject of Toreson's report was a girl aged 15 years with a history of prolonged malnutrition who died of a diffuse isolated myocarditis. Heart disease was known to have existed for at

least six months before death. Severe failure of the right side of the heart was progressive; left bundle branch lesion, heart block and ventricular fibrillation preceded death. The heart showed dilatation and hypertrophy with acute, subacute and chronic, noninfective inflammatory lesions diffusely distributed throughout the myocardium. The lesions were most extensive in the inner third of the myocardium, and in places they encroached on the endocardium. Mural thrombi were found in both auricles and in both ventricles. The possibility that the myocardial lesions may have been incited by prolonged dietary deficiency is suggested by the history of prolonged malnutrition. Deficiency of thiamine is particularly suspected.

Fatal Spontaneous Potassium Intoxication in Uremia.—Marchand and Finch report 2 cases in which potassium intoxication resulted from oliguria and failure of renal excretion. No potassium was given other than that contained in the diet and in the blood which was transfused into the first patient. The second patient did not have a blood transfusion and took no food during the week before death. The failure in excretion of potassium resulted in an increase in the concentration of potassium in the serum to 9.8 and 10.1 milliequivalents, while the concentration in the pericardial fluid was 9 and 8.8 milliequivalents and that in the spinal fluid 4.5 milliequivalents per liter at death. Serial electrocardiograms showed the characteristic changes leading to cardiac arrest by the action of potassium, including evidence of auricular arrest and progressive delay of conduction in the ventricles. The symptoms were those of uremia. Consciousness persisted up to the time of death in the first case but became clouded in the second case. In the first case the intravenous injection of a solution of calcium gluconate resulted in transient restoration of regular rhythm. The cessation of respiration in each case was preceded by circulatory failure, and there was evidence that the heart was arrested in diastole. In each of these cases the development of a high concentration of potassium in the serum was associated with failure of renal excretion sufficient to produce other evidence of azotemia. There was no indication of any toxic effect from potassium until after the interval of oliguria, and it is evident that there was no significant failure in excretion of potassium until after failure of water excretion had begun. The three sources from which the high concentration of potassium in the serum appears to have been derived were diet, red cells introduced by transfusion of blood and tissue metabolism. Of these the last in itself has regularly sufficed to cause death of animals with experimental anuria. In the second case the elevated level of potassium appears to have been derived largely from tissue metabolism, since no transfusion was given and no food was taken in the last week of life.

Subacute Endocarditis Associated with Spirillum Infection.—Hitzig and Lieberman observed an unusual case of subacute endocarditis in which the causative micro-organism was *Spirillum minus*. This organism was isolated six times from the blood in dextrose and tomato bouillon and grown in an atmosphere of 3.5 per cent carbon dioxide. Its relation to the causative organism of rat bite fever was established by its morphologic characteristics, its pathogenicity and serologic effects in man and its invasiveness for mice. Despite the unusual micro-organism, the clinical course and the changes observed at necropsy were strikingly similar to those observed in cases of the common form of subacute bacterial endocarditis due to *Streptococcus viridans*. The classic features observed in this case were low grade fever with occasional increases in temperature, endocardial murmurs, splenomegaly, multiple visceral and subcutaneous embolization, microscopic hematuria, petechiae, Osler and Janeway lesions and subarachnoid hemorrhage as terminal event. That the endocarditis was subacute was clearly established by its long duration, i. e. an interval of nineteen weeks from the earliest febrile episode to the termination of the illness. The isolation of *Spirillum minus* from the blood culture led to speculation as to the cause and pathogenesis of the endocarditis. At first there was doubt as to the etiologic role of the micro-organism identified as *Spirillum minus*, since there was no history of rat bite. On closer investigation it was

found that the food ingested by the patient at the water front was exposed to rats and wild cats. The patient also had direct contact with alley cats, a fact which might be significant, since a case of rat bite fever following a cat bite has been reported.

Interstitial Cell Tumors of the Testis: Report of 3 New Cases. E. F. Nation, H. A. Edmonson and R. W. Hammack.—p. 415.

Retroperitoneal Rupture of Duodenum.—Johnson reports the case of a boy aged 10, who was hospitalized twenty hours after having been struck by an automobile. The right side of his abdomen and back became progressively more tender, and he vomited whenever he attempted to take water; there was no blood in the vomitus. He had a normal bowel movement the following morning and normal urination. The abdomen was slightly distended and was more rigid on the right side. The points of greatest tenderness were the right costovertebral angle, the flank and the upper right quadrant of the abdomen. There was clear transmission of the cardiac sounds over the entire right side of the abdomen (Claybrook's sign). A few borborygmi were heard. There was a small area of ecchymosis slightly to the left of the umbilicus. A roentgenogram with the patient in the upright position showed no evidence of air in the peritoneal cavity, and the intestines were normal. Laparotomy was performed. The large and small bowel, stomach and urinary bladder were examined before a small area of edema and yellowish discoloration of the parietal peritoneum just lateral to the flexion of the duodenum was investigated. The visceral peritoneum was incised and explored, the lesion being easily found on the lower later curve of the posterior part of the duodenum. Mobilization of the duodenum was essential to identification and closure of the rupture. Drainage lasted several weeks. The author found 52 cases of retroperitoneal rupture of the duodenum by blunt trauma recorded in the literature between 1916 and 1943. In 7 of these the lesion was not found at the operation. Cure was obtained in 26 cases. Whenever edema, bile staining, hematoma or emphysema occur over the retroperitoneal area of the duodenum, the surgeon must explore. The rupture must be closed, but a short circuiting operation should be done only if the closure of the rupture produces obstruction. Proper drainage of the peritoneal cavity and the retroperitoneal space is essential. The stomach or duodenal tube must be used to put the traumatized area at rest. Sulfonamide drugs should be employed intelligently. Complications may arise following the treatment, the most serious of which are peritonitis, retroperitoneal cellulitis and duodenal fistula.

Intravenous Administration of Fat for Nutritional Purposes.—Dunham and Brunschwig found that dogs on a diet of commercial dog food of low fat content exhibited changes in the characteristics (iodine and saponification numbers) of the depot fat. Dogs receiving the same diet plus intravenous infusions of emulsified fat of appreciably different quality from dog fat did not exhibit sufficient differences from the control group in alteration of the iodine and saponification numbers to indicate appreciable physiologic storage of such infused fat. Changes in melting points of the depot fats in some of the animals given infusions, however, did suggest some storage of infused fat. Protein sparing effects were not demonstrable by intravenous injection of highly emulsified fat (except in 1 of 5 dogs), but such effects did result when comparable amounts of an emulsion were administered by mouth. This further indicated lack, or extreme limitation, of utilization of intravenously administered fat. Microscopic examination of tissues taken after infusions

ot fat showed increased fat in the liver, in macrophages in the spleen, in tubular epithelium of the kidneys and scattered sparsely in capillaries and macrophages in the lungs. After administration of coarser or less stable emulsions there were large fat globules in sinuses in the liver, often in the Kupffer cells and in sinuses in the spleen, increased fat in the renal tubules and glomeruli and pulmonary capillaries loaded with fat. The foreign fat diminished with the passage of time. There was an increased amount of hemosiderin in macrophages mobilized in the regions of accumulation of foreign fat especially in the spleen. The fat infusions produced severe secondary anemia, which disappeared after the infusions were discontinued. The infusions of fat were probably responsible for the deaths of 9 of 24 dogs, hence such infusions are not without danger. The surviving dogs appeared to maintain good health.

Resistance to Treatment in Early Syphilis—Katz stresses that resistance to therapy in syphilis is a serious problem for physician and patient and a menace from the public health point of view. He reports 3 such cases. Case 1 displayed an ocular relapse occurring after insufficient treatment and "cure" after intensified arsphenamine therapy. In case 2 a periostitis and precocious tertiary skin lesions developed while weekly injections of mapharsen 0.06 Gm. were being given but responded well to intensive therapy with arsphenamine. In case 3 resistance to neoarsphenamine 0.75 Gm. given once a week was observed and mucous patches and papular secondaries with spirochetes and periostitis developed. An interesting feature was the persistent seronegativity. Symptomatic cure was achieved with mapharsen 0.06 Gm. twice a week. In all 3 cases therapy previously considered as adequate failed to arrest progression of the syphilitic infection while intensified arsenical therapy brought about clinical and serologic cure. The author observed numerous patients in whom mapharsen given once a week, failed to reverse the positive blood tests, while more intensive therapy with either mapharsen or arsphenamine brought about serologic reversal in a short time. If general improvement serologically or otherwise does not occur with intensified therapy and change of drug such measures as injection of foreign protein, ultraviolet ray therapy and high vitamin intake may prove of value. If not, fever therapy in conjunction with arsenotherapy may be tried. The author has not observed resistance to treatment in primary or secondary syphilis when 0.06 Gm. of mapharsen was given twice a week. Mapharsen given once a week in a dose of 0.06 Gm. is insufficient for the treatment of early syphilis.

Program for Rehabilitation—Vonachen, medical director of the Caterpillar Tractor Company of Peoria, Ill., points out that this company realized about eighteen months ago that some of its thousands of employees now in service would return with physical handicaps. A survey was made in which each supervisor listed the jobs in his department which could be performed by employees with the handicaps listed on survey cards. With this information the personnel division, with its knowledge of "job analysis," was ready to interview the individuals and then present the applicant to the medical division for its approval of the specific job chosen. A personal interview followed, impressing on the employee the necessity for care and safety in his work. Many of the employees with physical handicaps are attending special classes given by a training school in order that they may advance in their quest of independence. This program has been successful, for the vast majority of these people have a production safety and absentee record above normal. They are paid the same rate as normal persons, they are shown no special favors and are in no way considered as accepting charity. In Caterpillar's handicapped group are only those with the loss of one or both extremities, pronounced deformities, loss of one or both eyes, loss of hearing and speech, and those with healed tuberculosis, heart disease and the like. At present Caterpillar has approximately 800 such handicapped employees, and this number is remarkable when consideration is given to the fact that it builds heavy machinery. After Caterpillar assured itself of the success of this program in its plant, it felt that the plan should be carried forward to the community. The idea was offered to the Peoria Manufacturing Association, and from this came "The Peoria Plan for Human Rehabilitation—Civilian and Military," which the author believes is the first to be established in a community with a complete working organization.

Roentgen Study of Primary Atypical and Bacterial Pneumonia.—Stein and Kresky state that during the twelve months from August 1942 through July 1943 2,062 cases of pneumonia were seen at the Regional Station Hospital in Sioux Falls, S. D.; 950 were bacterial pneumonias and 1,112 were primary atypical pneumonias. From a review of these cases they have come to the conclusion that any attempt to determine the probable etiology of a case of pneumonia from the roentgenogram alone is an extremely inaccurate procedure. Cases of primary atypical pneumonia may present an x-ray appearance indistinguishable from that of pneumococcal or other bacterial pneumonias, especially the early and/or resolving stages of the latter. Contrary to most descriptions in the literature, the authors have seen many cases of atypical pneumonia which did not originate in the hilar regions and extended outward but occurred as circumscribed foci in the periphery of the lung field. They have also seen primary atypical pneumonias occurring in the upper lobes with x-ray findings simulating those of tuberculosis, as mentioned by Moore and his associates. They present 19 cases which demonstrate the variations of x-ray shadows in both bacterial and primary atypical pneumonia. Any attempt to establish an etiologic diagnosis from the x-ray findings alone, without a knowledge of the clinical symptomatology, laboratory findings and clinical course, is certain to result in inaccurate diagnoses.

Roentgen Study of Primary Atypical Virus Pneumonia.—Levene and Sterman report studies in 100 consecutive cases of virus pneumonia observed in the Department of Radiology of the Massachusetts Memorial Hospitals. From a roentgenologic standpoint virus pneumonia appears to be a disease of the tracheobronchial system with secondary changes in the lungs. It produces fairly characteristic pulmonary changes. These consist of tracheobronchitis, peribronchitis, focal atelectasis, edema and emphysema. The presence of emphysema militates against total lobar atelectasis, so that uniform consolidation is infrequently observed. Roentgenograms show clearing of the lungs on the seventeenth day and a return to normal on the twenty-fifth day. Resolution progresses centripetally, the peripheral portions of the lungs being the first to clear. Roentgenologic evidence of interstitial pneumonitis and partial atelectasis may remain long after clinical cure. Since this may suggest the possibility of the development of chronic complications, particularly of bronchiectasis, it would appear to be good practice to take a roentgenogram of the chest on the day of discharge and another, where indicated, at a short interval thereafter.

Etiology of Postarsphenamine Jaundice.—Beattie and Marshall point out that apparently two types of hepatitis occur during arsenic therapy: (1) an early type, which is usually mild and appears within the first two weeks after the first injection of the drug, and (2) a late type, which may appear at a variable time after starting treatment but usually becomes obvious between the twelfth and seventeenth weeks of treatment. They are concerned with the late type, which at their clinic increased from 2 per hundred cases of early syphilis under arsenic treatment to 46 per hundred cases. Observations indicated that although syphilis and the arsenicals can produce liver damage they cannot be responsible alone for the increase in jaundice. Ruge had made the observation that in the German navy the incidence of jaundice in the syphilitic bore a relation to the incidence of infective (nonspirochetal) jaundice in the general population. The present rapid rise in the incidence of jaundice among the syphilitic in Britain also has been observed over a period when infective hepatitis was becoming increasingly common in the general population. The authors investigated the possible role of infection in 119 cases of postarsphenamine jaundice in which all the antisymphilitic treatment was administered at one clinic. The length of the incubation period and the possibility that an infective agent had been transmitted by inoculation suggested that postarsphenamine jaundice might be identical with the jaundice which occurs after the administration of human blood products or of yellow fever vaccine containing human serum. It was suggested by MacCallum early in 1943 that if transmission of the infective factor in postarsphenamine jaundice was due to inoculation of infective material contained in imperfectly sterilized syringes, then if each patient was given a syringe at the beginning of his treatment and received injections only by that syringe the transmission of infection ought to be eliminated. It was decided to give each of 10 patients with early syphilis a new and unused syringe for his exclusive use for all his injections. Such syringes and needles were washed and boiled both before and after each injection. Because of posting to units away from the command only 4 of the 10 were observed beyond one hundred and twenty days after the first treatment. No case of jaundice appeared in this group in spite of the fact that the patients were in contact for about the first fourteen days of treatment, and subsequently at least once each week, with men who later developed postarsphenamine jaundice. The authors present considerations which suggest that there is an X disease which has an incubation period of about twenty-eight to thirty days and is transmitted by contact

and a Y disease, which has an incubation period of eighty to one hundred days and is transmitted by inoculation of infective material (blood, serum or plasma). An attack of Y disease presumably confers no immunity against X disease. Evidence that an attack of X disease confers no immunity against Y disease is scanty and incomplete but is suggestive. Relapses of Y disease have been explained mostly on the grounds of an infection with X disease.

Nervous Complications of Infective Hepatitis.—According to Lescher, nervous symptoms occur occasionally during spirochetosis icterohemorrhagica and also, but even more rarely, during infective hepatitis. Meningitis is the nervous complication most commonly encountered in both diseases. Disease of the nervous parenchyma, though it does occur, is rare in both infections. The authors describe meningitis in a patient with spirochetosis icterohemorrhagica and also in 2 patients with epidemic hepatitis. In 1 of these 2 polyneuritis developed, and in the other hemiplegia, presumably due to an encephalitis, occurred within a few weeks of the attack of epidemic hepatitis. While the possibility of coincidence has been kept in mind, the probability is that the hepatitis and the nervous complications are but two phases of the same disease. This combination may be found to be not quite so uncommon as was formerly supposed, especially if the presence of latent jaundice is looked for in all cases of infective nervous disease of doubtful etiology.

Application of Dust-Laying Oils to Hospital Bedclothes.—According to Harwood and his associates the treatment of bedclothes with dust-laying oils for the purpose of reducing dustborne infection in hospital wards has been investigated. The application of from 3 to 7 per cent of liquid petrolatum or of technical white oil to bedclothes caused a large reduction of dustborne bacteria in the air of hospital wards. Two distinct methods of applying the oil to bedclothes were studied: (a) impregnation with oil dissolved in a volatile organic solvent, (b) impregnation with concentrated oil-in-water emulsions. Neither of these processes permits accurate control of quantities, while both methods entail a recovery process for the unused oil and would present considerable difficulty in large scale operation in a hospital laundry. The National Institute for Medical Research invited the cooperation of the British Launderers' Research Association with regard to this difficulty, and an investigation was carried out in which the use of dilute aqueous emulsions for oiling was considered in detail. As a result of this work an efficient and economic process has been evolved. It has been found possible by the use of suitable emulsifiers to oil hospital bedclothes to any required degree by means of very dilute oil-in-water emulsions. The particular advantage of the present process is that complete exhaustion of the emulsion takes place, and there is therefore no necessity for applying an oil recovery process to the used liquor. Both positively charged and negatively charged oil emulsions have been employed, either separately or in equivalent amounts. The cation active emulsifier "fixanol C" and the anion active emulsifier "tecpol" have been used in the present investigation, but there is no reason why other commercial emulsifiers of similar types should not be used. The methods described are applicable on a large scale in any hospital laundry that observes a correct washing technic.

Oiled Floors to Control Respiratory Infection.—Anderson and his associates investigated the oiling of floors to see if it could be used to cut down the spread of air borne infections among soldiers in barracks. The experiment involved men in two army units, A and B, each of which was a large training center occupying one complete barracks. Oiling of floors was carried out in unit A, while, in unit B, which served as a con-

trol, the floors were untreated. The two barracks were almost identical in structure, and the men in the two lived and worked under closely comparable conditions. In unit A the wooden floors of all barrack rooms, sleeping huts, offices and lecture rooms were treated with spindle oil at regular intervals. The oil was applied in such a way as to leave an imperceptible film on the surface after thorough impregnation of the wood. Oil treatment of the floors of unit A began in November 1942. The oil was noninflammable and caused no unpleasant smell. The surface dried in about six hours. One gallon of oil was enough to treat about 1,000 square feet of floor space. Second and subsequent applications were made at intervals of about four weeks. After treatment the floor was not scrubbed but was easily kept clean by brushing or occasional moppings with a rag moistened in oil. The floors of unit B—the control unit—were left untreated, and in both units careful weekly records were kept of all men reporting sick with a respiratory infection during the seventeen weeks ended March 27, 1943. In the unit where floors were oiled the average rate of respiratory infections was 7 per thousand men, as against 38 per thousand men in the control unit. No major outbreak of respiratory infection appeared in the test unit; in the control unit an outbreak of almost epidemic proportions prevailed between the middle of February and the first week of March.

Neurologic Syndromes Due to Tuberculosis of Nervous System.—Matte L. and Galecio G. report 5 cases of tuberculosis of the nervous system complicating primary pulmonary tuberculosis in infants and young children. Neurologic symptoms were present in 4 cases. The first patient exhibited symptoms of a cerebral tumor. The second and third patients presented hemiplegia as the first symptom of terminal tuberculous meningitis of ten and five days' duration respectively. The fourth patient complained of acute supraorbital neuralgia for the last four months in the course of primary pulmonary tuberculosis of nine months' duration. Necropsies showed primary pulmonary tuberculosis with cavitation and hematogenous spread of tuberculosis in all of the cases. A large cerebellar tuberculoma was found in the first case. A large cerebral tuberculoma was present in the second and third cases. Multiple cerebral tuberculomas were encountered in the fourth case. Neurologic symptoms of definite value for the diagnosis of cerebral tuberculoma did not appear in the last three cases in which tuberculoma was a necropsy finding. The cause of death in the cases reported was tuberculous leptomeningitis.

Book Notices

The Evolution of Tuberculosis as Observed During Twenty Years at Lymanhurst, Minneapolis Board of Public Welfare, 1921 to 1941. Price, \$2.50. Paper. Pp. 253, with Illustrations. Minnesota Public Health Association. St. Paul, 1944.

This volume is the result of twenty years of observation and study of tuberculosis among children and young adults who as far as possible were observed to determine how the disease evolves in the bodies of persons who are infected in infancy, childhood and early adult life.

The tuberculin test, the author believes, affords the best criterion of the accomplishments in tuberculosis control over a period of years as well as the present situation.

During the first ten years stereoscopic x-ray films were made of the chests of all children, regardless of the tuberculin reaction. Never was any evidence of clinical tuberculosis found in the lungs of nonreactors. Therefore, x-ray inspection of the chest was discontinued. Moreover, single films were substituted for stereoscopic films. In 1934, after adequate trial, x-ray film on paper base was as satisfactory as on celluloid base, and therefore the paper x-ray film of the standard size was subsequently employed. It was concluded that no x-ray film, regardless of base or size, is adequate for final diagnosis. X-ray film inspection of the chest is indispensable in detecting the presence of disease which has attained macroscopic proportions, but microscopic etiology can never be determined with accuracy from the shadows of macroscopic lesions alone.

Among those who had primary tuberculosis as manifested by the tuberculin reaction, the x-ray film revealed evidence of such lesions in only about 30 per cent. The x-rays cannot be considered a substitute for the tuberculin test, but neither is the tuberculin test a substitute for the x-rays. In observing the chests of the same individuals over a period of years, it was found that the location of the lesions in those who develop chronic clinical pulmonary tuberculosis can often be determined by x-ray inspection two or three years before they cause significant symptoms or become contagious and usually before other phases of the physical examination are of any avail. Despite these findings, the physicians did not abandon palpation, percussion and auscultation, which often bring to light evidence of disease in certain areas of the lungs and in other parts of the body which do not lend themselves well to x-ray inspection.

After thirteen years of observation and study, it was decided that treatment of children with the first infection type of tuberculosis is of little avail, either immediately or remotely, and therefore it was recommended that the treatment division of the Lymanhurst School be abandoned and that the funds be diverted to more effective tuberculosis work; namely, testing as many children as possible with tuberculin, the reactors to be examined periodically after attaining adulthood, and examining their adult associates for contagious tuberculosis and breaking the contact as soon as possible. This necessitated a clinic for adults where such contacts could be examined, which was established in 1935.

Observations proved that the first infection type of tuberculosis is an extremely benign disease. Over the twenty year period no child was found to be significantly ill from this form of tuberculosis. However, it prepared the way for reinfection clinical forms of disease by causing sensitivity of the tissues to tuberculo-protein and often by providing tubercle bacilli for reinfections. Acute forms of the disease, such as meningitis, miliary disease and pneumonia, are reinfection types of tuberculosis. Nearly always when an opportunity exists one can detect the presence of primary tuberculosis before these highly destructive reinfection forms appear.

The belief that children under 5 years of age tolerate infection with tubercle bacilli poorly was not substantiated. In a group of 813 children who were found to be reactors to tuberculin between birth and the age of 5 years 11 (1.35 per cent) died of meningitis, miliary tuberculosis or tuberculous pneumonia. Eleven others as children developed extrathoracic clinical tuberculosis, of whom none died. There were 9 who later developed chronic pulmonary tuberculosis. The average age at which this occurred was 14.5 years, the youngest being 8 and the oldest 18 years. All the remaining children of this group

remained free from clinical tuberculosis throughout the period of observation.

Various methods of finding clinical cases of pulmonary tuberculosis were tried, but it is pointed out that the only entirely satisfactory method consists in testing all persons in a community with tuberculin, making x-ray films of the chests of the reactors periodically and examining those who have shadows to determine the cause of their disease.

Since the first infection type of tuberculosis does not confer dependable immunity, as does an attack of smallpox, attempts to produce immunity by other methods are based on a shaky premise and do not appear to be the proper approach to the solution of the problem. The only known satisfactory method of preventing tuberculosis in the human body consists in creating an environment free from tubercle bacilli.

This volume has added much valuable information to the literature of tuberculosis and should be read by all physicians interested in the diagnosis, treatment and prevention of the disease.

Reaction to Injury: Pathology for Students of Disease Based on the Functional and Morphological Responses of Tissues to Injurious Agents. By Willey D. Forbes, M.D., Professor of Pathology, Duke University and Pathologist to the Duke Hospital, Durham, N. C. Cloth. Price, \$9. Pp. 797, with 332 illustrations. Baltimore: Williams & Wilkins Company, 1943.

"In its present form this book is made up of two of the four parts called for in the original plan of the work. The two parts constitute a clearly defined entity, dealing with the nature and causation of disease and with the resistive reaction: the inflammatory process and all the infectious diseases that arise therefrom." Interest centers in the individual as a whole and the old, more conventional treatment of the subject as "special" pathology has been avoided. In the preface the author explains that in order to meet the needs of continuous education and to provide opportunity for cultivation of knowledge of the basic science of disease "a specific theme has been adopted, and the materials have been selected, arranged and dealt with in such a way that the theme is always evident—disease is a matter of the abnormal outcome of a constantly changing relation between the ultimate biological unit, the cell, and its environment."

Part one, approximately one sixth of this volume, is an introduction to the study of disease. The evolution of present day concepts of the nature of disease is presented in an interesting and stimulating fashion, so devised as to give the beginner an important and all too frequently neglected historical background. The etiology and pathogenesis of disease receive particular emphasis; especially notable is the elaborate classification and discussion of pathogenic agents of the plant and animal kingdoms. According to the author's plan "the individual is considered to be capable of reacting in only three essential ways, (1) by resisting, (2) by submitting and (3) by effecting an adaptation. These three reactions, therefore, are taken to be the basis of all disease, and the recognized disease entities are considered to be the expressions of the elaboration of one of several of these reactions."

Any general plan for the formal presentation of a subject as complex as pathology must represent some sort of compromise and thus be open to certain adverse criticism. The plan followed in this work is no exception. One of the most difficult and complex parts of pathology, the inflammatory reaction, is introduced at the beginning without the preparation that a detailed study of simpler reactions, e. g. hyperemia, hemorrhage, edema or various degenerative processes, would afford. Such sharp distinctions are made between the various "parts" of pathology in this work that the student is often presented with what must seem to him a fairly complete discussion of a disease, yet some very important complication or end result of the disease may not be included because it does not fit in with the particular phase of pathology being discussed. An example of this is found in the discussion of chronic osteomyelitis, in which no hint is given of the possibility of amyloidosis as a complicating factor. Similarly, for rheumatic heart disease there is practically no discussion of its most important sequel, the heart failure which often follows long after the acute inflammatory episode, due to cicatricial changes. In spite of the evident intention to emphasize general principles and mechanisms, the

result is not all that might be desired. Too often a comparatively brief discussion of general principles is followed by the presentation of numerous disease entities which seem to be rather detached from one another and but weakly connected with the important principles which they are supposed to illustrate. Of 646 pages concerning resistive reaction to injury it seems rather disproportionate to devote but two thirds of a page to metabolism and functions in inflamed tissues, two and one-half pages to the functional significance of the elements of the inflammatory exudate, and but one page to a general discussion of repair of tissues following the inflammatory reaction. It is difficult to criticize fairly half a work without knowledge of just what the other half contains. It does appear, however, that in a "completed treatment of resistive reaction to injury" cirrhosis of the liver and asthma, for example, should be considered and, furthermore, that some general statements should be made regarding the role that hyperplasia, metaplasia, hypertrophy, regeneration and fibroplasia may have in a resistive reaction to injury.

A major defect of this volume, and one which detracts especially from a new work, lies in the selection of reference material. For example, concerning such an active subject as rheumatic fever the average date of publication for the 70 references given lies between 1924 and 1925. Less than 10 per cent of these were published within the last ten years. Similarly for the subject of experimental nephritis the most recent of the 11 references is 13 years old, antedating one of the most important advances in this field: the production of glomerulonephritis with nephrotoxin. Heffron's monograph on the pathogenesis of lobar pneumonia is referred to twice, with the implication that this represents the last word on the subject. This work is 13 years old and does not include some of the important experimental data on which our present day concepts of this disease are based. Even in the field of virus diseases, where new knowledge is increasing rapidly, the most recent of 11 reference on general considerations of virus diseases is 7 years old.

Especially commendable in this book are the portions which deal with specific granulomatous diseases, and the large sections on virus and rickettsial diseases. There are numerous illustrations of exceptional quality from the standpoint both of technical excellence and of suitability. The material is well indexed except for an occasional rather important omission, e. g. hyperemia and rheumatic fever (listed as acute rheumatic fever). The text is well printed on paper of excellent quality and the volume is attractively and sturdily bound.

It is doubtful that this work will supplant the several excellent single volume textbooks of pathology now in use; however, it presents many exceptional features including a rather complete coverage of the acute inflammatory diseases. Part I provides an excellent introduction to the study of pathology and disease in general.

Small Community Hospitals. By Henry J. Soultmays, Director, Division of Rural Hospitals, The Commonwealth Fund, and Geddes Smith, Associate, The Commonwealth Fund. Cloth. Price, \$2. Pp. 132. New York: Commonwealth Fund; London: Oxford University Press, 1941.

This is a book of importance to any one who wishes to establish a hospital of 50 beds or less. Its practical point of view will appeal to members of the medical profession and to leaders of the community who might be given some responsibility in the establishment of a small hospital. Many of the subjects discussed will apply to institutions having a larger bed capacity, but the reader is cautioned that all remarks cannot apply to hospitals having more than 50 beds. Larger institutions can expect to have the services of a qualified pathologist and a qualified radiologist to supervise the laboratories. Small institutions cannot afford adequate supervision but should nevertheless strive to maintain some professional supervision of these departments. Exception should be taken to the apparent reliance on recently graduated technicians of commercial training schools. Undoubtedly small, recently established hospitals would profit by obtaining the services of experienced technicians and preferably a technician who is registered by recognized organizations such as the Registry of Medical Technologists or the American Registry of X-Ray Technicians.

Common Skin Diseases. By A. C. Roxburgh, M.A., M.D., B.Ch., Physician in Charge of the Skin Department and Lecturer on Diseases of the Skin, St. Bartholomew's Hospital, London. Seventh edition. Fabrikoid. Price, 18s. Pp. 453, with 192 illustrations. London: H. K. Lewis & Co., Ltd., 1944.

This is the seventh edition of Roxburgh's book to appear since its first publication in 1932. That fact itself attests its value. Like the previous editions, it is a clearly written book designed for the general practitioner, with emphasis on the commoner diseases, their differential diagnosis and practical therapeutic procedures such as the practitioner is in a position to give. It is a book written from experience, rather than a compilation of abstracts from the literature, and written with a style that is readable, conversational and understandable. The type is large, the stock excellent and the photographic illustrations plentiful, large and clear. It does not pretend to be a complete treatise or reference work, yet it contains information about the newer things, as the vitamins, sulfonamides, penicillin, the influence of war on certain dermatoses and industrial dermatitis. Emphasis throughout the book is placed on the broader conception of dermatology rather than on minutiae. Within its scope it is an excellent book that fully deserves recommendation.

The War and Mental Health in England. By James M. MacIntosh, M.D., Professor of Preventive Medicine, University of Glasgow. Cloth. Price, 85 cents. Pp. 91. New York: Commonwealth Fund; London: Oxford University Press, 1944.

This monograph includes two parts. The first part contains chapters on the process of adjustment, the lonely year 1940-1941, defense, preparation and alliance 1941-1942 and the end of the beginning 1942-1943. The second part contains chapters on hospital services, voluntary organizations for mental health, professional education in mental health and some problems of the future. The author discusses the psychodynamics of normal thinking and abnormal thinking as well as many other mental aberrations deftly, simply and accurately. His proposal to educate every one regarding proper, normal and clear thinking is commended. When the war is over people must begin to busy themselves with the vocations, jobs and responsibilities they had before. When mental disease develops it must be treated as is any other disease, as quickly as possible. Education in regard to mental health according to the author should begin early in life and be continued throughout life. There are myriads of excellent ideas in this small publication.

Poliomyelitis: The Relation of Neurotropic Streptococci to Epidemic and Experimental Poliomyelitis and Poliomyelitis Virus. Diagnostic Serologic Tests and Serum Treatment. By Edward C. Rosenow, M.D., Professor of Experimental Bacteriology, University of Minnesota, Mayo Foundation, Rochester. Vol. A44 The International Bulletin for Medical Research and Public Hygiene. W. L. Cuzco, Editor-in-Chief. Paper. Pp. 87, with 26 illustrations. New York, Brussels & London: International Bulletin, [1944].

The author summarizes his researches over many years on the problems indicated by the title. No new evidence is presented in support of his well known views with regard to the causation of poliomyelitis, but he gives a comprehensive, painstaking and helpful account with full references of the many experiments and observations previously reported in medical journals. His hope is that the monograph "will meet the objections that have stood in the way of a general acceptance of the primary streptococcal causation of poliomyelitis and the streptococcal source of the virus."

Healthful Living for Nurses. By Harold S. Diehl, M.S., M.D., Sc.D., Professor of Preventive Medicine and Public Health and Dean of the Medical Sciences, University of Minnesota, Minneapolis, and Ruth E. Boynton, M.S., M.D., Professor of Preventive Medicine and Public Health and Director of the Student's Health Service, University of Minnesota. Cloth. Price, \$2.50. Pp. 331, with 31 illustrations. New York & London: McGraw-Hill Book Company, Inc., 1941.

This textbook on healthful living for nurses is complete, authentic and readable. It is amply documented, the references being given chapter by chapter, together with discussion suggestions. It is organized as a textbook for the obvious purpose of being used in nurses' training schools. As such, it should be of the greatest usefulness. It is liberally illustrated with charts, diagrams and drawings. It can be recommended without reservation.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CLOTTING OF MENSTRUAL BLOOD—SIGNS OF FETAL DISTRESS DURING LABOR

To the Editor:—What pathologic or physiologic changes occur in the menstrual blood when clots form? In the normal woman one does not expect to find clots. I realize that fibroid tumors and other glandular disturbances may produce clots, but I should like to know why this occurs. If meconium appears in the vaginal discharge of a patient who is having a normal labor and the fetal heart rate becomes rapid, changing from 140 to 170, what would one expect as the cause and what can be done? Such a patient was examined rectally; there was dilatation of about two fingerbreadths, there was no evidence of cord prolapse and the patient was in good condition. At this time she was given a hypodermic of vitamin K but the baby died a few hours after birth and at the time of birth showed asphyxia. I have often seen meconium stained amniotic fluid when the baby would be perfectly normal. Are there any precautions or any special procedures that should be taken when meconium stained fluid appears during the course of labor before the cervix is dilated?

M.D., Washington.

ANSWER.—Under normal conditions menstrual blood does not clot, because in passing through the endometrium it undergoes certain changes which tend to inhibit coagulation. The nature of these changes is obscure, but presumably some anticoagulant substance is added or some ingredient of the blood necessary for clotting is removed. Since blood obtained from a needle prick of the cervix does clot, it is clear that the anticoagulant mechanism resides in the endometrium. While this mechanism is adequate for the usual quantity of menstrual bleeding, it may be unable to cope with excessive hemorrhage, and under these circumstances clots develop. As a rule, therefore, clot formation in the menstrual discharge means a more rapid escape of blood from the endometrium than is normal.

The two most dependable signs of fetal distress in labor are a slow fetal heart rate (under 90) and irregularity. A rapid rate (170 and above) and meconium stained amniotic fluid are less trustworthy signs and may be present in cases in which the fetus is entirely normal. Accordingly, the latter two signs should not be regarded as indications for immediate delivery unless the cervix is fully dilated with the head on the perineum. If the cervix is not fully dilated the best results will be obtained in the long run if labor is allowed to continue. Indeed, operative intervention prior to complete dilatation is rarely justified even if unequivocal signs of fetal distress occur, because (1) the trauma imposed on the baby by such an operation often does more harm than the continuation of labor and (2) it is not right to jeopardize the mother's outlook by a traumatic operation for the sake of an infant whose chances of survival are already dubious. The administration of oxygen to the mother in such cases may be helpful. A rapid fetal heart rate is presumably the result of a temporary vagal paralysis, but the causes which bring about the latter condition are not definitely known.

AGGLUTINATION OF TYPHOID-PARATYPHOID AND DYSENTERY ORGANISMS

To the Editor:—What is the significance of a positive serum agglutination test for paratyphoid A in a titer of 1:320 in a patient who had a severe attack of diarrhea lasting forty-eight hours four months before? Could a recent immunization against typhoid and paratyphoid produce agglutinins against paratyphoid organisms? M.D., South Carolina.

ANSWER.—It is assumed that the Flexner bacillus, *Shigella paratyphenteriae*, is meant by paratyphoid A. Though normal human serum frequently agglutinates this organism to a high titer, often 1:150 and sometimes higher, a titer of 1:320 in the absence of agglutinins for Shiga's bacillus is suggestive of infection. The agglutinin titer usually drops rapidly after recovery, and its persistence for as long as four months might be taken to suggest a carrier state. However, the significance of the presence of agglutinins for dysentery bacilli, and the Flexner bacillus in particular, is questionable and should be interpreted with caution; the only completely satisfactory diagnostic test is the isolation of the bacillus from the feces.

A recent typhoid-paratyphoid immunization might produce an anamnestic rise in dysentery agglutinins but probably not to the observed titer. Though a number of strains of the Y type of Flexner's bacillus have been found to contain Salmonella anti-

gens VI and XIII (Bornstein, Siegbert; Saphra, I., and Daniels, J. B.: *J. Immunol.* 42:401 [Dec.] 1941) the occurrence in dysentery bacilli of antigens present in the typhoid bacillus and the paratyphoid A and paratyphoid B bacilli has not as yet been observed.

NEURITIS PROBABLY FROM IODIZED POPPY SEED OIL IN SPINAL CANAL

To the Editor:—Five cc. of iodized poppy seed oil was injected intrathecally and cisternally because of pain, hyperesthesia and anesthesia along the course of the 6th cervical dorsal nerve roots C₆ through C₈ on the right, with generalized weakness of the right arm. For twenty-four hours following there was severe headache, general malaise and a temperature of 102. For two weeks the patient could not lie flat because of pain in the lumbar and sacral regions. This disappeared to be followed by coccygeal neuritic pain on sneezing or on laughing heartily. Three months after injection there were severe neuritic pains in the right sacroiliac region, right hip and right posterior thigh, coming on after standing or walking and relieved by lying down. Are the pains due to the injection? Should an attempt be made now after almost four months to remove the oil? How is that done? The patient is a 35 year old man.

M.D., Rhode Island.

ANSWER.—One would have to consider the possibility of a protruded cervical disk in this patient. It is rather unusual to have a unilateral neuritis.

The coccygeal neuritic pain produced on sneezing and laughing following the injection of iodized oil suggests that the patient has probably developed some neuritis as the result of the oil. The removal of the oil is probably advisable. However, before this is done another fluoroscopy should be made with the oil of the lumbosacral area and of the cervical area either to verify or to disprove the presence of protruded disks in both locations. Following this, the iodized oil should be removed with a spinal puncture needle placed in the fourth lumbar space according to Kubik and Hampson's technic (Removal of Iodized Oil by Lumbar Puncture, *New England J. Med.* 224:455 [March 13] 1941), which consists in adjusting the table so that the volume of oil is placed about the tip of the spinal puncture needle, at which time gentle suction with the use of a syringe should effect a thorough removal. It is true that the last remaining drops of oil have to be recentered about the needle in order to remove it thoroughly. The centering of the oil about the needle is done with the aid of the fluoroscope.

IMPAIRED HEARING FROM ACOUSTIC TRAUMA

To the Editor:—A man aged 38 who claims no previous trouble with his hearing developed bilateral total deafness while working as a chipper in a shipyard. His Wassermann reaction is negative. A change of position has not improved his hearing. A neurologist states that there is no neurologic basis for his loss of hearing and that it is not psychogenic. His ear drums are normal. If chipping noises are the cause of his deafness, what is the pathogenesis? Would this be considered as an accident or an occupational disease?

J. Douglas Barry, M.D., Wilmington, Del.

ANSWER.—Impaired hearing from acoustic trauma is characterized either by a slowly progressive hearing loss beginning for the tone of 4,096 vibrations or, if there has been a sudden loud sound close to the ear, there may be an acute onset of a hearing loss. It would seem unlikely that a bilateral total deafness such as described could be the result of acoustic trauma and could be classed as occupational. The pathogenesis of deafness from acoustic trauma is an initial fatigue of the auditory nerve followed by progressive degeneration as the exposure continues.

JUNGLE ROT

To the Editor:—Will you kindly send me all the information you have on the treatment, prognosis and pathology of a disease known as jungle rot? Will you tell me something about the etiology and contagiousness of the disease?

M.D., California.

ANSWER.—The United States Army Medical Department has no information concerning the disease called "jungle rot." Perhaps the term applies to a condition known as "Barcoo rot," which is a synonym for "desert sore" or "veld sore." References to this condition may be found on page 1107 of Stitt's "Diagnosis, Prevention and Treatment of Tropical Diseases" by R. P. Strong and on page 679 of the eleventh edition of "Manson's Tropical Diseases" by Philip Manson-Bahr.

From Panama comes information that the terms "jungle rot" and "tropical rot" are used by laymen to describe any sort of sore developing on the body, usually a severe form of mycotic fungus, mold or yeast infection.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE
DEPARTMENT, MAY-AUGUST 1944

Titles have been listed or abstracts made of important articles in the following journals in the Current Literature Department of THE JOURNAL during the past four months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1933. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "OS," Organization Section; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 1264.

A

AADTP Mixture: See Diphtheria, Immunization
A B C nostrums, 737—BI
A. F. of L.: See Industrial Trade Unions
A.S.T.P.: See Education, Medical
ABANDONMENT of Patients: See Medicolegal
Abstracts at end of letter M
ABBOTT-Miller Tube: See Miller-Abbott tube
ABDOMEN: See also Gastro-intestinal Tract;
Pelvis
appendix in left lower quadrant, 820
cancer, supraclavicular signal node in, [Viacava] 233—ab
disease, mechanics and pathways of pain, [Rivers & Roodenburg] *421
hemorrhage, intra-abdominal apoplexy, [Haugen] 934—ab
injuries, retroperitoneal rupture of duodenum, [Johnson] 1212—ab
injuries, treatment of peritonitis after, [Hejduk] 937—ab
pain: tender over aorta, use ergotamine tartrate for, (reply) [Perelson] 92
pain, with obscure febrile illness, 177
surgery, abdominoperineal resection for rectal cancer, [Coller] 315—ab
surgery, early rising after, [Powers] *1080
Viscera: See Viscera
ABDOMINAL Belt, effects on blood pressure after sympathectomy, [Gambill] 379—ab
ABNORMALITIES: See Crippled; under specific organ or region; Bladder dilatation; Luangs; Patella; Spline; Urethra stricture; Uterus
ABORTION, criminal, danger of intrauterine soap pastes, [Wellerstein] *205; (fatal fat embolism from interruption) [Strassmann] 673—C
criminal abortionists prosecuted, Minn., 1150
criminal, German sentenced to death for, 712
criminal, osteopath ends life while on trial, Minn., 665
criminal, osteopath sentenced for, Calif., 664
Rh factor and, [Reynolds] 456—ab
statistics; control by antepartum allowance, France, 855
threatened, prauono and progesterone for, [Fluhmann] *4
ABSCCESS: See Furunculosis; Ulcers; under organ affected as Liver
ABSENTEEISM: See Industrial Health, workers, absenteeism
ABSORPTION: See under organ, region or substance concerned as Fat; Sulfonamide Compounds; Vitamins A
ABT, ISAAC A., nominated for A. M. A. Distinguished Service Award, 563—OS
ACADEMIC freedom and medical education, 533—E
ACADEMY: See American Academy; National Academy; under Societies at end of letter S
ACCELERATED Courses: See Education, Medical
ACCIDENTS: See also Disasters; Trauma; World War II, casualties
fatal, falls leading cause of, 74
First Aid for: See First Aid
Industrial: See Industrial Accidents
ACCLIMATIZATION, equilibrium involved in, 353—E
ACETANILID poisoning from B. C. headache powder, [Kracke & Platt] *107
ACETATES, dermatitis from, [Hall] *184
ACETYL Derivatives of Sulfonamides: See under names of specific sulfonamides as Sulfanilamide
ACETYL-BETA-METHYLCHOLINE Chloride: See Mlecholy
ACETYLCHOLINE, etiologic role in myasthenia gravis, 790—E
ACHALASIA: See Stomach, cardiospasm
ACID, acetylsalicylic, aspirin as home canning powder (Council report) *353
acetylsalicylic, prothrombopenia induced by, effect of vitamin K and ascorbic acid, [Shapiro] *546; (correction) 923

ACID—Continued

Amino Acids: See Amino Acids
p-aminobenzoic, in vitiligo, [Beinhauer] 232—ab
ascorbic, effect on prothrombopenia induced by aspirin, [Shapiro] *546; (correction) 923
ascorbic, for anemia in children, [Davidson] 175—ab
ascorbic, loss in minced salads after using steel vs. plastic knives, 276—E
ascorbic, minimum needs of adults, [Kyhos] 385—ab
ascorbic, tablets, N.N.R., (Smith-Dorsey) 1093
boric, 5%, impregnated gauze for burns, (Joint Council report) *973
boric, labelling changed, 505
boric, to be colored, (Chicago) 159; (New York) 161; 729
boric, use in home canning, (Council report) *355
Cevitamic: See Acid, ascorbic
chronic, dermatitis from, [Hall] *184
citric, in tablet emergency ration, 494—E
heptadecarboxylic, bismuth salt of in lonsillitis, [Stovin] 382—ab
hydrochloric, plus sodium thiosulfate solutions for scabies, 879
lactic, injection destroys motor end plates, 791—E
lactic, milk mixture as corrosive poison for premature infants, [Young & Smith] *1179
Mesoxalic, Ureide of: See Alloxan
Nicotinic, Diethylamide of: See Nikethamide
nicotinic, Nicotinamide, N.N.R., (American Pharmaceutical) 1098
Picric: See Trinitrophenol
sulfuric, dermatitis from, [Hall] *184
Tannic: See also Burns, treatment
tannic, liver necrosis from, [Harkins] *335
tannic, toxic effects, 507
ACIDITY, Gastric: See Stomach
of sweat, effect on pearls, 238; (reply) [Alexander] 1074
ACIDOLATE as skin cleanser for acne vulgaris, [Swartz & Blank] *30
ACNE: See also Chloracne; Furunculosis
vulgaris after using androgens, [Thompson] *19
vulgaris, liver extract in, [Marshall] 85—ab
vulgaris, pregnant mare serum for, [Biringer] 753—ab
vulgaris, sulfated oil (Acidolate) as skin cleanser, [Swartz & Blank] *30
ACROMIOCLAVICULAR Injuries: See Shoulder
ACTINOMYCOSIS, treatment, sulfonamide, [Benbow] 993—ab
treatment, penicillin, [Herrick & others] *1009
ACTIVITY, early postoperative [Powers] *1079
early puerperal, [Rotstein] *838
ADDICTION: See Alcoholism; Cannabis Sativa; Narcotics
ADDISON, WILLIAM, origin of cell theory in pathology, 912—E
ADDISON'S DISEASE and chronic adrenal insufficiency, [Thorn] *11
functional renal insufficiency in, [Lazaro] 293—ab
treatment desoxycorticosterone effect on blood pressure, [Perera & others] *1030
treatment, desoxycorticosterone, heart size in, [McGavack] 379—ab
ADENITIS: See under Lymphatic System
ADENOMA, chromophobe, of pituitary, with hypogonadism, [Thompson] *17
Toxic, of Thyroid: See Goller, Toxic
ADENOMYOSIS: See Endometriosis
ADHESIONS, meningeal, use of fibrin foams and fibrin films, [Ingraham] 310—ab
ADOLESCENCE, heart rates after exercise in, [Gallagher & Brouha] *835; *836
health of R.A.D. girls, Germany, 1143
physical defects in, [Witzbach] *823; [Gallagher & Brouha] *834; 850—E
precocious puberty in boys and androgens, [Kenyon] 751—ab
Youth Allah, physical development, 300

ADRENALIN: See Epinephrine

ADRENALS: See also Addison's Disease
blood chemical changes in manic-depressive psychosis dependent on, 277—E
cortex extract, clinical use, [Thorn] *10
cortex extract for burn shock, [Harkins] *534
cortex extracts, untoward effects, (Council report) *786
Cortex Hormone (crystalline): See Desoxycorticosterone
cortex insufficiency, [Thorn] *11
Hemorrhage: See Waterhouse-Friderichsen Syndrome
Hormone (sympathetic): See Epinephrine
inhibit release mechanism in cancer, [Goldweber] 512—C
pituitary interrelated to, 1054
roentgen irradiation in angina pectoris, [Raab] 451—ab
tumors, [Cahill] 597—ab
tumors; 17-ketosteroids in urine, [Callow] 875—ab
ADVERTISING: See also Medicolegal Abstracts at end of letter M
A. M. A. Cooperative Medical Advertising Bureau, 645—OS
of drug products, names of diseases in, (Council discusses) 209
of special purpose foods, (Council discusses) 429
"patent medicine" ballyhoo on radio, 150—E
ADVISORY Board for Medical Specialties, *147; *1132
AERODONTALGIA: See Teeth
AERONAUTICS: See Aviation
AEROSOL OT, wetting agent given orally, 320
AFRICA, War in: See World War II
AFTERBIRTH: See Placenta
AGAR, brain-heart infusoid blood agar to identify streptococci, [Pilot] *1037
AGE, Adolescent: See Adolescence
carcinogenic effect of estrogens in mice, 33—E
middle age, mortality rates over and under 50, 1162
Mother's: See Maternity
Old: See Old Age
AGGLUTININS AND AGGLUTINATION of typhoid-paratyphoid and dysentery bacillus, 1218
Rh: See Rh Factor
tests, obtaining blood from infants for, [Sauer & others] (footnote 4) *949
AGGLUTINOGEN, Rh: See Rh Factor
AGITATED Depression: See Psychosis, manic depressive
AGRANULOCYTOSIS, ACUTE, familial chronic, [Benez Cesar] 815—ab
ALBUMIN, [Ussery] 396—ab
Allt: See also Oxygen; Pneumatic borne infections, oiled floors to control, [Anderson] 1215—ab
Compressed: See Calsson Disease
conditioning of Army hospitals in India, 493
disinfection, Guth Lamp, 1189
disinfection, penicillin for, 1011—E
injection for orbit roentgenography, [de Abreu] 358—ab
Presence in Cavity: See Pneumothorax
Pressure Gun: See Grease gun
pressure (low), myocardial infarction from, [Hammonds] 812—ab
AIR FORCE: See Aviation; World War II
AIR PASSAGES: See Respiratory System
AIRPLANES: See Aviation
ALBUMIN in Urine: See Albuminuria
unknown type isolated by Straub called sktu, 217
ALBUMINURIA, allergy relation to, 1071
ALCOHOL, Addicts: See Alcoholism
Problem in relation to crime and mental disorders, [Kolb] 591—ab
ALCOHOLISM, delirium tremens, hypertonic saline in, [Silverman] 356—ab
program, Michigan, 73
ALEPPO Ball: See Leishmaniasis of skin
ALUTIAN, medical mission to study, 920
ALIMENTARY Tract: See Digestive System

- ALKALI, use in sulfadiazine therapy, [Rohr] 874-ab
- ALLERGY: See Anaphylaxis and Allergy
- ALLIES: See World War II
- ALLOCATIONS: See Priorities and Allocatable
- ALLOXAN diabetes with complications, [Bailey] 938-ab
- ALLOYS, aluminum, dermatitis from, [Hall] *183
- ALPHA Omega Alpha Lecture: See Lectures "ALTERNATIVES" and Iodides, 177
- ALTITUDE, high: See also Aviation
high, myocardial infarction in gnomes, [Hammonds] 312-ab
- pains, [Rosenblum] 871-ab
- ALUMINUM, dermatitis from, [Hall] *183; *184
- hydrolytic gel effect on gastric secretion, [Adams] 809-ab
- powder for silicosis, [Crombie] 872-ab; 1001
- ALVARENGA Prize: See Prizes
- AMALOT dermatitis from, [Schwartz] *188
- AMBULANCE: See also Hospitals, ships; Hospitals, train
- plane, evacuation of wounded, (173,000 in 1943) 37; 177; (Navy inaugurates coast to coast service) 283, (to U. S.) 435, (2,000 in Burma) 853, (in Burma; Col. Phelinger's account) 916
- service, civilian, 639
